If the wires are properly proportioned and through any means those of opposite polarity (positive and negative) are brought into metallic contact, a path of low resistance is then established and an excessive flow of current results with the same consequences as before.

Derived circuits established to and through the earth caused by defective insulation, even though the points of contact be widely separated, will bring about this same result.

It is true that safety fuses are brought into play to prevent occurrences of this kind, but it is not an unusual thing to find fuse wires at the junction of circuits and branches far in excess in carrying capacity of the wires they are designed to protect, and it is not unusual after the fuse wire has performed its functions by melting, to find it replaced by one whose fusing point is many times in excess of the original; and I have known cases where, after the failure of the largest fuse wire to maintain the continuity of the circuit, copper wire was substituted therefor.

I next come to the fuse blocks or bases. The earlier types were of wood, contact between wires and fuse secured under screw heads. The inevitable shrinkage of the wood destroyed the contact, and heat or a series arc was the first result, and later a fire, insignificant or of considerable magnitude according to circumstances. Too often these devices were concealed from view, thus increasing the hazard.

Next come the switches for turning on and cutting off this supply of current. When mounted on wooden bases they were capable of doing all the mischief ascribed to the wooden base cut-outs. In addition to this may be cited imperfect contacts, introducing an excessive amount of resistance and increasing the temperature to an unsafe point. The inexcusable practice of placing switches of insufficient capacity is sure to bring about the same results.

That undesirable trio, the combination fixtures for gas and electric lights, the cheap insulating joint and wood or fibre base cut-out, concealed under the metal canopy of the fixture, has been and is now another fruitful source of trouble and added fire hazard. The heat from the gas burners on a large fixture causes the fibre insulation to shrink, permitting the gas to escape, in small quantities at first, but steadily increasing in volume. The contact between the screw head and fuse is destroyed from the same cause, a slight arc established, the escaping gas ignited, the fibre in the joint burned, and a burning gas flame, limited only by the size of the pipe, is the result.

Next in order comes that twin brother in iniquity of the swinging gas jet, the so-called flexible cord, to the ends of which are suspended so many incandescent lamps. The best of this is not safe in some locations, such as show windows or any other place where it is in close proximity to inflammable goods, while the cheaper grades are positively dangerous in nearly all places. While the use of this may be admissible for suspending lamps in the usual way in buildings which in themselves are of slow burning construction, and contain little that is inflammable, the practice of fastening it to the walls or ceilings, either by means of cleats or staples, or concealing it between floors and partitions cannot be too severely condemned. Such a practice adds another to the fire hazards of electricity.

Next comes the wires for incandescent electric lighting, their character and the methods of installing them. It goes without saying that the very best of insulating covering is none too good for electric light wires. It should be water-proof in many positions, while there are cases where this is not necessary. Another desirable quality it should possess is non-inflammability, but very little of the best grades of insulation for wires possesses this desirable feature. Wires covered with any known grade of insulation, held in place by wooden cleats, add to the fire hazard to a greater or less degree, depending on their location, the distance between opposite poles, and the care with which they are placed in position. Wires that are concealed between floors, ceilings and partitions, where not supported on non-inflammable insulators, and are permitted to rest on gas, steam, water or hot-air pipes, or other conductors, dependence being placed on the covering of the wire to prevent electrical contact, add to the fire hazard. When wires of opposite polarity are run through a single hole in wooden joist, beam, stud or partition, and are laid side by side without proper means of separation, they add to the fire hazard, due to the fact that the best form of insulation has a limited life, and to the other fact that the ever-present rodent finds some forms a dainty morsel when nothing better can be had. As a result of their feast an arc may be established, and if the insulation is highly inflammable, a fire between the ceilings and partitions is rather apt to follow. Loose connections and poorly made joints are another addition to the fire hazard. Joints when improperly made and not soldered soon become a source of danger. Solder alone will not insure a perfect joint and immunity from excessive heat at this point.

The practice of enclosing two wires of a circuit covered with a high grade of insulation in an insulating tube that is itself highly inflammable is another addition to the fire hazard.

All the causes assigned for increased fire hazard to this system of electric lighting is applicable to the system known as the alternating or transformer system, with the exception of the fact that the amount of current it is possible to convey into a building is limited to the capacity of the transformer. The lamps used on this system are usually what are known as fifty volts, and the current necessary to bring them to a state of incandescence is about one ampere. A 75 light transformer then could deliver only about 75 amperes.

I have endeavored as far as possible within the limits of this paper to give most of the causes for increased fire hazards due to electricity. It is due, however, to those engaged in the various branches of electric industries and those who use electrical energy for light, power or the transmission of intelligence, to state that many of the devices I have condemned are not now manufactured, although many are still in use, and that many of the bad practices that I have condemned are not indulged in by reputable men and firms.

I firmly believe that electricity in the service of man can be rendered docile and harmless, but to point out the manner in which this desirable end can be attained is beyond the scope of this paper and the limit of the time allotted to me at this meeting. This, however, might be made the subject of another paper.

I will now close by saying that the man or firm who will take advantage of the limited knowledge of electricity possessed by the average citizen, and install electric wires in such a way as to increase the fire hazard, should be deemed guilty of a misdemeanor, and should fire result should be deemed guilty of arson. The electric lighting company who would connect its service wires and furnish current to a building unsafely wired should be deemed an accessory before the fact and punished accordingly.

It is within the power of those engaged in installing electric lights and wires and furnishing electricity for light and power to greatly reduce the fire hazard, and stop the complaints of underwriters of the increased number of fires due to electricity.

DISCUSSION.

At the conclusion of Captain Brophy's paper the Chairman called upon Mr. Parshall, of the General Electric Company, to speak on the topic. In complying with this request Mr. Parshall said that the General Electric Company had facilities for manufacturing and supplying every kind of electrical apparatus for the distribution and utilization of current. Besides supplying such apparatus they had also issued full and explicit instructions and directions to their customers and the public generally how properly to handle electrical machinery. In reference to the absorbing subject of losses by fire occurring through electricity, he could say that such loss had been proven to be not more than 1 per cent. of the entire loss. In Boston there had been several great conflagrations which had been attributed to electricity though it was not proven. In Philadelphia, St. Louis and other cities, fire losses through the electric current had been but a small fraction of 1 per cent.

Something had been said about the dangers of inside wires. It was true there might be some slight danger at times, but if only the public would show a willingness to pay a little more for electrical appliances, things could be made safe enough. Cheap work and cheap labor were a mistake in such a business.

With a view to allaying public fear as to the dangers of overhead wires, his company had all along maintained that all low potential wires should go underground. Such a change had been completed in London, Chicago and elsewhere, with gratifying results, and it would be well to insist on the change being made over here.

In connection with the subject of fire hazards, the great trouble of overhead wires was the obstacle they raised in the way of those who had to fight the fires. The supposed dangers attending the transmission of power did not exist to the extent supposed. The electric current had been found to be so useful and convenient that nowadays people forgot to use the most ordinary precautions in dealing or handling it, but the action now being taken by the various insurance corporations was stirring up public interest, and more care would be used in future. Even manufacturing and construction companies engaged in electrical work were now interested in doing the best work only. Because of the appearance and rumored dangers of electric wires, the public had become prejudiced against them. Take the reports of the various fire departments throughout the country, and it would be found that the number of fires caused by electricity did not reach 2 per cent. of the entire number. In view of what had been said and written at various times about the dangers of electricity, the different companies stood ready to do everything necessary to obviate all dangers. The interests of the people and the interests of the electrical fraternity were identical, and as public needs indicated themselves the electricians were always ready to be up and doing.

A gentleman who spoke for the New England Telephone and Telegraph Company said that his company had nearly solved the problem by placing all but a few of their wires underground. The rest would disappear shortly. Captain Brophy was asked if the introduction of electricity had increased the fire risks, to which that gentleman replied that it had not increased those risks by increasing the number of fires.

Professor Charles R. Cross, of the Massachusetts Institute of Technology, remarked that the unwillingness shown by the public to pay a fair price for electric devices had been somewhat overstated. In the early days of the business poor apparatus was too often put in, the use of which shook public confidence in the value of electric lights. Improvements, however, had been made year after year, though even to-day some poor machines were still being sold and used. After any serious conflagration the investigations disclosed that not always were the best devices used. What applied to construction work likewise applied to the machines themselves. Manufacturers had put out machines they would rather not have sold but for the public demand. Originally a current of 6 or 7 amperes was supplied and was considered sufficient; to-day a current running from 60 to 70 amperes was a common thing. When the demand was simply for everything of the very best quality, the manufacturers would be ready to meet the demand.

Col. Hewins said that it was not always the fault of the manufacturers that other than the best apparatus was supplied. The demand for cheap goods was the source of much of the evil. Several years ago the New England Electric Exchange accomplished great good by the improvements it encouraged in every department of the business, and such an organization would be of value even to-day.

Mr. T. Wright of the General Electric Company, in answer to a question from the chairman if anyone present could inform the meeting if there was known to be an efficient underground conduit in existence, said that for some time he had been working on that special thing and had found that there were many and great difficulties to be surmounted. Different styles of conduits had been experimented with, including the Bentley-Knight system, but none as yet had been found practicable. In Europe they had been somewhat more successful in such work, though even there the only conduit system that could be considered a success was the system in use in Buda-Pesth. The terrible weather of winter was the great obstacle to be overcome in this country, and it remained to be seen if that obstacle could be successfully dealt with.

Mr. Blodgett, electrical superintendent of the Boston and Albany Railroad, who presided over the meeting, closed the discussion by relating several instances in which the telegraph system of the Western Union Company had been more or less seriously affected by induced currents from electric railways operated at quite long distances from the place where the effects of these currents were noted.

A vote of thanks to Captain Brophy closed the proceedings.

The Cost of Steam Power Produced With Engines of Different Types Under Practical Conditions; with Supplement Relating to Water Power.

BY CHAS. E. EMERY, PH.D.[*]

DISCUSSION.

The President—I think the impression which many of you have received is the same as my own—of surprise that there is so little difference between the total cost of power for the different classes of steam engines. Any one who has been called upon to make a selection of a steam plant, and has received from fifteen to twenty bids from different builders, together with the claims for economy made by each, has been much in doubt as to the wisdom of a final judgment. I must confess that I myself have often been confused by the conflicting claims, and I think the paper which has been presented to-night will aid every engineer in settling these oftentimes puzzling questions.

The conclusions which Dr. Emery has reached in the matter of the use of water power in plants for the electric transmission of power is similar to that which I arrived at some time ago. Before I go into any details, however, I shall ask Professor Forbes—who I see is present, and who by reason of his experience and his present connection should be well qualified, not only to give us his views upon steam plants, but particularly upon combined hydraulic and electric plants—to say a few words upon this subject.

Prof. George Forbes—Everybody, I am sure, must appreciate what enormous importance this paper is going to be to us all. No doubt there are many others here who have been in the same position in which I have been placed in the course of the last year, who have had to make a special examination of this very question, and all those who have had to deal with the utilization of large quantities of water power, estimating the value which that water power is to those who are exploiting it, must have been forced to do what they could to estimate the value of the horse power when developed in the most economical means by steam power. I have in these investigations during the last year had the good fortune to be assisted by the experience of some of the most experienced engineers in this country, including one whom we all respect, who is mentioned by the author of this paper, Mr. Leavitt; and I would only say generally that the conclusions which have been come to by myself and those who have given me their assistance agree extremely well with the conclusions at which Dr. Emery has arrived. I must say that Dr. Emery has put the case in a much more general way and much more applicable to a great variety of circumstances that actually do exist in practice than any estimates I have ever seen of the actual cost of the horse-power, and consequently it is possible for us in any particular case that we are considering to pick out the conditions which most nearly approach what is in the case that we are studying. And while I may say that some estimates I have seen of the cost of a horse power per annum, especially on a ten hours a day service, come out a little below what Dr. Emery has produced, I must add that in those cases certain items of expenditure have been omitted, and in the cases where a lower estimate has been arrived at the compiler has been professedly trying to produce the lowest figure which the users of water power would ever have to contend against.

I would feel that it is hopeless without having given a great deal of time to prepare remarks on this paper to say anything much to the point. But I would ask the author one or two questions about it. In the first place as to the cost of the coal I noticed that the heat-producing power of the coal is assumed to be the same in all cases. Now I fancy that these tables may lead to a little misunderstanding in the minds of some. I imagine some one taking up this table and saying: "Now what will it cost us at such and such a place to produce a horse-power per annum? There is coal purchasable at this place at $2.00 per ton. There is also coal purchasable at $4.00 per ton." He will naturally say I will choose the coal at $2.00 per ton. That gives him a certain definite price on this estimate; but, of course, the slack at $2.00 per ton would only produce about one-half the heating power of coal at $4.00 per ton. In giving the price of coal it seems to me it ought to be mentioned what the calorific power of the coal is, and I would ask Dr. Emery whether he has in all these cases considered the calorific power of the coal practically the same.

I would ask Dr. Emery whether he considers that 500 horse power is a sufficiently big amount to be considered. I mean are the standing expenses of a 500 horse-power plant sufficiently divided over the power to make it fair? If you went to 10,000 horse power, for instance, would the standing charges be less in proportion to the horse power, or is 500 horse power sufficient to take up the whole of the value of the fixed expenditure? That is to say, are all the brains and all the bodies that are at work on the plant fully occupied with 500 horse power or would a larger unit modify the result?

I will not take up the time of the meeting with remarks which I feel are not of very great value, and I will only make a few remarks about the supplementary portion relating to water power. The cost of putting in the plant has been taken at probably $140 per horse power without electrical transmission. Now it seems to me it is almost an impossible thing to make a definite estimate like that, the cost of the water power applied depends so entirely upon the local conditions in the first place, and secondly upon the magnitude of them. Where you have got a large head the cost is generally very much less than where you have a very low head. When you have to dam up a river, of course the expense per horse power of the preliminary work is generally much greater than with a waterfall, and of course the cost of the actual turbines is very much greater when we have low heads than where we are using a very considerable head. Another point is that the cost per horse power in the use of water power diminishes enormously with the magnitude of the works. When you are dealing with 100,000 H. P. the cost for each horse power becomes very much less indeed. I should say that this $140 was a price that would be fair for a moderate fall and for very few thousand horse power. But when you come to larger amounts I think it would be considerably less.

The President—I wish to say a few words concerning the transmission of power by electricity over long distances with water power as the prime source of energy. I have always tried to avoid being over enthusiastic in dealing with a commercial question of this character. The habit is too common to assume, now that electric transmission is a possibility, that possession of a water power is necessarily something of a bonanza, and that all that is necessary to convert it into tangible wealth are a few electrical adjuncts. Both the economies and the possibilities in electric transmission are overstated, too many conditions are overlooked, too many possibilities of failure ignored. I made the statement some years ago that it was very questionable whether in an ordinary case transmission from a water power to a city twenty to twenty-five miles away with reconversion in a sub-station and redistribution for lighting or power purposes was an attractive commercial enterprise, and that if a man wished to distribute power in a manufacturing district he would probably do better to put in a well equipped steam plant of large size, well located with regard to railroad facilities, with supply of coal at reasonably low rates, and distributing at a constant potential of 500 to 600 volts, than he would to attempt to replace the steam plant by a system of electric transmission with water power behind it twenty miles away. I believe the general statements which Dr. Emery has given here to-night confirm this conclusion, and that we should avoid expecting to much from the transmission of power by electricity. I am not authorized to make any statement concerning the intentions of the promoters of the enterprise with which the last speaker is connected, but I believe that I am safe in saying that this great development of water power at Niagara Falls, which is so interesting from the standpoint of the hydraulic engineer, is not designed so much for transmission of power to a distance as it is for local transmission and for the local development of manufacturing industries requiring large units of power. The electric railway engineer is frequently called upon to pass upon the question whether for railroad purposes it is possible to use water powers even ten or fifteen miles away from the centres of distribution, and he cannot but appreciate the lack of sound information upon that subject, and the folly of many of the visionary assumptions made by railway managers with regard to this problem.

---

[*] Read at the Seventy-fifth Meeting of the American Institute of Electrical Engineers, New York, March 21, 1893. (See ELECTRICITY, Vol. IV, No. 11.)

Prof. Forbes—Might I say, as a sequel to what you have just stated, of course the question of the cost of the work at Niagara we have worked out very fully, and I think I may say that we know what it is going to cost, both the electrical transmission to Buffalo and everything, but you will readily see that it is hardly possible for me to speak very freely about that just at the present time. But as to the question of transmission to a distance, although it is naturally the desire of those associated with it to develop the power in the immediate vicinity, in the meantime the extra cost of transmission to a distance of fifteen or twenty miles is almost insignificant. When the details of these plans are published you will be astonished to see what a very little difference that really does make when we come to the actual machinery that will be put down.

The President—Perhaps I do not make myself sufficiently clear in that matter. Take the case at Buffalo for example; let us see how electricity is used there. There are, generally speaking, the arc and incandescent light plants, the stationary power service and the railroad systems. The arc lamps run on constant current circuits with varying potential. Some of the incandescent lights probably run on alternating current circuits; others run on 110 and 220 constant potential circuits. Railway motors run in a 500 volt constant potential circuit. These various systems of distribution are distinct in themselves. They have practically but one thing in common, that is, they are driven by steam engines. The moment you leave the belt of the steam engine or its coupling and go to the dynamo the character of the transmission is changed. Now to operate these various systems from a distant source of power there is only one thing that is practically possible, that is to substitute for the boilers and engines in the several stations represented by different financial interests, or in some common station controlled by all, motors driven by the electric plant twenty miles away which is in turn driven by turbine wheels. The substitution of the secondary part of this plant is not practicable; it has a character determined by the local demands and conditions. There is undoubtedly a field for the transmission over long distances of large units of power for special purposes, and also under conditions where the cost of coal is prohibitory and where perhaps it cannot be obtained at all, but I think that from a general commercial standpoint the statement I have made will be found correct in practical experience.

I appreciate that Professor Forbes is in a somewhat delicate position in speaking of what is to be done at the Niagara plant, and perhaps I ought not to have suggested so plainly that he was somewhat better posted than most of us as to the actual cost of transmission for the distances in question and for the larger units.

Mr. Samuel McElroy—To an engineer who has been a long time in practice, a paper like this, replete with the study of a profoundly analytical mind, comes not only as a most valuable contribution to its subject matter, but as a characteristic index of the professional progress of the day.

The time when many professional men were much troubled with petty personal jealousies, and with the idea that their shop secrets were their most valuable stock for employment, has happily been changed. The advanced progress of science, keeping step with, but always in advance of, the material progress of the country, and the beneficial results of society life, have done much to improve the systems of mutual help and to broaden the standards of professional service, and the result, as one of various indications, is shown in papers which condense in a few columns a wide range of experimental and practical research and result, for the direct benefit of professional brethren.

We have then, rising above the class which is content with a low standard of work, and adds little to the general fund of information, and the class which dwells continuously in the confined atmosphere of school-boy mathematics, rapidly developing into splendid, aggressive life, the men of true professional dignity, who neglect no details which involve principles, but give principles their true rank. These are the burners of midnight oil; men who love their work for its own sake, and not for what it pays; who are too high minded to waste time in personal jealousies; students too ardent to turn aside for commonplaces, and ever ready to put their most valuable acquisitions at the service of their professional brethren, as such papers as this illustrates.

One of the specially valuable features of this paper is its careful condensation into a brief space of a wide range of experimental practice, and how a wide grasp of such practice simplifies apparently contradictory or complicated conditions every experienced engineer learns the more he learns.

In the feverish spirit of the day, which for want of just this balance of forces tends to run to excess after every new theory, very great waste of time and money is made, which better habits of concrete analysis would have corrected. We go through spasmodic public excitements often which are only spasmodic. Not so very long ago, the whole railway world was astir over the merits of the " broad gauge " railroad track, and trunk lines like the "Erie" and others must have six and seven feet gauges. Some years after, the same fever ran to a three and a-half feet gauge; and it is only lately that common sense has brought our general railway system into standard gauge, and even this the pedagogues of the profession are continually tampering with.

The question of cost of steam power in itself, and as developed by different classes of engines adopted, or now being adopted, is here carefully analyzed in its proper commercial condition. Steam power, we see here, means something more than a boiler, a cylinder and a line of shafting. It means not only boiler plant and cost, with all the accessories; not only engine plant and attachment; engine house, chimney and appurtenances; coal supply, combustion rate and cost; but other conditions are important. There are daily operation as to running time; relative engine friction; pressure economy; feed water temperature, evaporation, spare pipes and valves; repair, depreciation, supplies; interest on construction and plant; inspection, insurance, taxes, dividends, surplus power and like conditions, which enter into the general problem of use and cost, and are here carefully analyzed and tabulated.

As to these analyses, their basis of arrangement is so clearly explained that special corrections for special cases can readily be applied.

As in my own expert practice I have frequently been required to demonstrate the economy, fitness and special value of water power, if I should venture any opinion on the valuable analysis here made, of comparative steam and water power, it would be to say only this:

That it is quite certain that water falls and flows to the sea by gravity much more cheaply than coal can be mined, and is likely to outlast coal; that water power plant is far less expensive, as a rule, than that of steam, and its daily care much less expensive; that at the centres of such power, Lowell, Lawrence, Holyoke, Cohoes, etc., their common annual rental of about $20 per H. P. (ordinary mill day) has induced the most elaborate outlay of capital, and resulted in very remunerative income.

I think, therefore, that on general analysis water power does not cost as much as steam. While it must be admitted that very expensive reservoirs and other structures, as at Lowell and Lawrence, aggregate what Dr. Emery's analysis shows; yet at Lowell the "Central Pacific" mill prefers in low runs to pay $60 per H. P. for surplus water to using its own steam plant; that for somewhat large consumption of special power, $3.00 per week is a common steam power price at Lowell, Boston, New York and other places.

The estimated cost of development on the Hydraulic Tunnel of Niagara is about $2,238,750 for a capacity of 119,000 H. P., or about $10.50 per H. P., for slopewalls, cribs, races and gates, and tunnel. The rates, as published, are for 5,000 H. P. and over, $10 per H. P. per year; 4,500 H. P., $10.50; 4,000 H. P., $11, down to 300 H. P., $21. On the old Hydraulic Canal, powers have been leased as low as $4 for 600 to 1,000 H. P., and $5.30 for 250 to 300 H. P. Such leases are, of course, improperly cheap, as are, in fact, the general rates of the new tunnel.

On the Kennebec River, Maine, I found a working power, at Carritunk Falls, under 28 feet fall, of about 7,000 H. P. This river, on its upper basins, has remarkable natural reservoirs of about 229 square miles, with about six feet available storage, in a main basin of 2,860 square miles. A main dam of 80 feet controls the flow, and nature has singularly formed the races and wheel pit; so that the cost of these items is much less than that of Niagara.

In cases like this, then, the superior economy of water power must be conceded; and in pulp mills, as at Carritunk, the large quantity of water needed is also an important item of cost.

These, however, are not criticisms on the elaborate and most valuable paper of Dr. Emery; they furnish modified conditions of use, which no engineer will apprehend and appreciate more thoroughly than he.

Mr. J. F. Holloway—I read with pleasure the paper that Dr. Emery has prepared, and I want to say that I agree heartily with my friend, Mr. McElroy, in the complimentary remarks he made about the paper. The paper is one that will be of great value to mechanical as well as electrical engineers. It is evidently the result of a great deal of study and care on the part of the author, and in its result it is to some extent surprising; and yet, after all, it coincides very closely with ideas that I have had all of my life—that this is a world of compensation, that we do not get all the good things in one place without having to take some other things that are not quite so good.

The results he shows are as between the more common and the highly refined engines, and the ultimate results that are shown in his paper are not so widely different, and that will be, I think, a matter of some surprise to many, until they investigate the matter in the direction and to the extent in which Dr. Emery has investigated it. The common idea is, that to get the best results you must get the most refined mechanism, and considerable money is often spent in that direction without knowing how much in other respects the total value of the saving is brought down to the results obtained by the plainer and more common machines.

Prof. John H. Barr—I came down here this afternoon to hear the third reading of this paper. I had the privilege a short time ago of hearing a dress rehearsal of it, and read it to-day on the cars. I hope this, however, is not the final reading as it is one of the things that grows on me.

I noticed a reference to the condition of affairs at the Calumet and Hecla mines. My first engineering experience was gained at the Calumet and Hecla mine, and while I was there in a subordinate capacity and perhaps not entirely competent to judge of things, I think it quite probable, if not certain, that the conditions have by this time been so modified that a different policy might be pursued with economy, so far as distribution of power is concerned. The great work done at Calumet by Dr. Leavitt is of the highest interest to engineers, and if he has kept his eye rather constantly on columns *c* and *f* of the table given in this paper, it can be said that few men have done as much with a pound of coal as he.

The Falls of St. Anthony is cited as an exceptional case where nature has greatly favored the locality in water power; and while its water power had a very important influence in the development of the city located near it, I doubt if its present influence is as great as most people think. I believe that steam mills at other places can now compete on very fair terms with the mills on the water power at St. Anthony. The supply of water is so variable that all the more important mills have to have large steam plants—steam plants sufficient to practically run the entire mill. The interest, and all costs except running expenses, go on for this part of the plant whether the mill is run by steam or water. The cost of labor also is largely maintained whether run by steam or water, because the engineers have to be employed throughout the year in order to have them when needed. The value of land and high taxation, or rent, put these mills at a disadvantage, largely compensating the gain due to running by water part of the time.

Mr. C. O. Mailloux—In regard to the utilization of water power when used to generate electricity to transmit to a distance, there is one factor that appears to me to be of importance as affecting the question whether a given transmission scheme is financially practicable or not. I refer to accessory machinery and apparatus, particularly that needed for regulation and control, the importance and the cost of which I think are often underrated if not neglected in making estimates on the cost of machinery necessary to utilize the energy of water power by transmission to distant points. What would be the result when transmitting 5,000 horse power electrically, from a generator driven by a turbine, supposing the load was suddenly and totally relieved by the circuit being opened through a main fuse blowing out, or a break in the wire, or supposing it were suddenly thrown on without giving time for the governor to act; or again, suppose the load were constantly fluctuating as it does on most railroad circuits. It occurred to me that something would happen of interest to science and possibly the coroner also. We can hardly have fly-wheels sufficiently large to take care of these fluctuations, as they must be of enormous size.

I have always found the principal difficulty of electrical transmission projects to be to dispose of the electrical energy after it is transmitted, and especially to distribute it or deliver it to the consumer in a satisfactory manner.

Prof. Forbes—I would say that in the case of the Niagara transmission that question has been thoroughly threshed out and we have got a fly-wheel, not at all gigantic in comparison with the revolving armature, which completely takes care of that. In two seconds the regulator will have acted and the fly-wheel will have taken care of it up to that time.

The President—I think in the larger plants where five or six thousand horse power units are used there will be less difficulty possibly than is anticipated, because as a rule, where transmission from a single source of such large units to distributed work for stationary purposes there is a certain averaging up of the duty which will prevent such sharp variations of the load as have been indicated, and hence I do not think there will be so much difficulty on the large water power transmissions; still, these variations have to be guarded against and it is more difficult to meet them in a water plant than in a steam plant.

Dr. Emery—It is unfortunate that the paper is so long that few have had time to study all the points in their different bearings and relations to each other, and I am quite sorry that one whom we esteem so highly as Prof. Forbes should have received a copy only an hour before the meeting. I should have been very much pleased to have his remarks, excellent as they were, based upon a more thorough study of the paper. I quite agree with him on the point he makes in regard to the quality of the fuel. This matter should be emphasized in every way. At the same time it is not neglected in the paper. I will read Section 25, page 111, upon that point:

"In column *m* is shown the weight of water which it is assumed will be evaporated per pound of coal. The assumption is 8½ pounds, except in the last case where it has been fixed at 9½ pounds. Although 9 and 9½ pounds evaporated can be obtained under actual conditions readily with boilers of good proportion and construction, it is thought that 8½ pounds is as much as can be depended upon in average practice. It is, in fact, greater than is obtained in most cases, though less than is claimed in exceptional ones. This rate must be considered somewhat in relation to the price of coal. If cheap coal is to be used which will not give 8½ pounds evaporation, the results must be sought in the column of the table applying to coal of a higher price."

The last clause of the quotation, it will be seen, exactly covers the point made by Prof. Forbes in regard to cheaper coals. They will not give 8½ pounds evaporation. The better grades of anthracite coal of buckwheat size will rarely evaporate over 8 pounds of water from actual pressure and temperature, and for the poorer qualities 7½ pounds or even less can only be depended upon. If, therefore, such coal cost $2.00 per ton, the results in the table should be mentally interpolated between those for $2.00 and $3.00 per ton. A glance at the figures in the two columns will show that any such difference will not appreciably alter the relative performance of the different engines if the same coal be used in all cases. The absolute results for a particular engine would of course be changed.

The next question is whether or not 500 horse power is a sufficiently large unit for general consideration. Prof. Forbes did not use the term unit, but I think that will express his meaning. I used 500 horse power as being more generally applicable than a larger unit. It is in fact much larger than the average, but sufficiently large to secure maximum performance in the engine. The results would not be materially changed if we were to consider larger plants as multiples of a 500 horse power plant. The cost of fireman would not change at all, and though one engineer on watch might care for an engine of more than 500 horse power in a large plant, a chief engineer would also be employed at a higher salary, so that the labor account would not be greatly modified. The table is therefore about right for any large plant.

Prof. Forbes—For how small a plant is it right?

Dr. Emery—I do not think that the operating expenses of a steam plant of 2,500 horse power or containing several units of that size would vary from one of 500 horse power, or made up of several units of that size, sufficiently to predict in advance which would have the advantage. As already stated, one engineer on watch would take care of more horse power in large units, but the number of men required to do the overhauling on the spare engine and the salary of a chief engineer or general superintendent would balance, or more than balance, the apparent saving for attention. For electric lighting work the principal saving due to the use of 2,500 horse power or other large units would be in the cost of real estate and buildings. In New York City, for instance, the area is limited, land is high priced, and the larger units take less floor space, so that considerably more engine power can be crowded into the same space, and this may make considerable saving in first cost.

Prof. Forbes, in the short time he has had to examine the paper, has not quite understood my first remarks in relation to the cost of water power. Moreover, the preliminary statement in the supplement to the paper is necessarily incomplete and was rendered much more so in attempting to abstract it. Prof. Forbes says: "The cost of putting in the plant has been taken at probably $140 per horse power without electrical transmission." I wished to be understood that $140 per horse power was about the maximum amount that could be expended to develop a water power on a 10-hour basis in competition with steam, and I showed that the expenditures on the Merrimac had reached this sum and that if they could be recalled they would not now be warranted. It was not intended to intimate that water power could not frequently be developed for a less sum.

It will be observed that I have not attempted to discuss the details of electrical transmission. President Sprague has pointed out the nature of the difficulties. I, however, desire to call attention to the fact that the method I have adopted is the proper one. The total cost of plant to deliver the power from the waterfall to the work to be done, which I typify as a jack-shaft, cannot, in competition with steam and cheap coal, greatly exceed $140 per horse power on a 10-hour basis and $200 and upward per horse power on a 24-hour basis. This cost of plant includes, first, the original investment in the general development of the water power which to the consumer may appear as rental charged by the water power company; second, the cost of installing turbines and dynamos to generate the electric current; third, the cost of the electric line, and, fourth, the cost of the motors which turn the wheels, or the illustrative jack-shaft, at the point of delivery. *The motor must be included in the cost*, as then only is the result comparable with steam power on the basis shown in the table. The comparison is independent of the work done by such jack-shafts, as in either case it can be employed in generating electric current at lower tension for general distribution, or utilized directly to operate large mills or manufactories.

I trust that further discussions may be sent in by manufacturers and engineers to whom the paper has been sent, and will be specially obliged for any information tending in particular cases or under particular conditions to modify the statements as to costs and prices given in the paper as a basis for comparison. I have been assured this evening by the operating superintendent of an electric station, who does not wish to rise, that my estimates of the cost of supplies, repairs and renewals is too low to apply to high speed engines of large size operating electric plants. This is an important point which I hope will be fully elaborated by those at liberty to talk freely on the subject, as it may show the desirability of using engines of fairly slow speed rather than the cheaper ones running at high speeds compared with their size. Engines of the old slow speed type are now run much faster than formerly, and it may be that a compromise class of engine will soon be designed to which neither of the common names can be applied, which will be cheaper than the slow speed engine and yet not run so rapidly as to cause the difficulties which some have experienced with certain types of high speed engines.

The President—I had intended to point out, which I will now do very briefly, that it is most important in considering the transmission of power by electricity from original water power plants that the conditions of construction under least cost should be considered. Some few years ago I prepared a paper which was read before the Franklin Institute which brought up that question. The conditions were given for continuous current transmission, although they would probably need to be modified for alternating current transmission, and I presume the same general laws will hold.

Removal Notice.

After May 1, Mr. George Cutter, and his large line of specialties, will be found at 851-855 The Rookery, Chicago. An increased business has rendered larger quarters a necessity.

Captain William Brophy.

This gentleman, whose portrait we herewith publish, is entitled to rank as one of the best known and most highly esteemed men in this country. For many years he has been identified with the insurance interests, and at the present time is electrical engineer and inspector for the Associated Factory Mutual Insurance Companies whose headquarters are in Boston.

Ever since the introduction of electric lighting and power on a commercial basis, Captain Brophy has occupied a similar position, and it is no exaggeration to say that there are few men in the country better equipped with practical knowledge of every branch of the electrical business, while as an insurance expert he has no superior.

CAPTAIN WILLIAM BROPHY.

In the pursuance of his business and the discharge of his responsible duties he has had to travel all over the United States, and it is doubtful if there is a large electric lighting or power plant anywhere which he has not visited, inspected and reported upon.

In connection with that whilom useful organization, the New England Electric Exchange, which did such valuable work a few years ago, Captain Brophy was one of the moving spirits. He aided in its foundation, and took an active part in its administration to the end of its career.

Many of the young men to-day occupying responsible positions as superintendents and managers of central stations or isolated plants are deeply indebted to Captain Brophy for the valuable assistance they have from time to time received from him in the way of instruction and encouragement, for he has a sincere love for young men who are capable and ambitious, and we know of many who can testify to the kindly manner in which they have been helped over difficulties, had problems solved for them, by this veteran worker in the two important fields of electricity and insurance, while investors, capitalists and property owners everywhere esteem him highly for the valuable assistance he has always rendered in bringing about reforms and improvements in the art and practice of installing electrical apparatus of every kind so as to secure the highest efficiency and economy in service with a minimum of risk to life and property.

Captain Brophy has a very happy faculty of lucidly presenting statistics, arguments and explanations pertaining to his business. He has read many excellent papers at electric light, power, street-railway and insurance conventions, which are entitled to rank in their published form among the most valuable contributions to the literature of electricity and insurance. In the present issue of our journal will be found his latest utterance on "Fire Hazards of Electric Lighting," a paper which was read before the Boston Society of Arts on Thursday evening, 13th inst., and evoked an interesting discussion of the subject now engaging so much public attention.

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

European Lighting Practice.

Mr. W. S. Barstow, of the Brooklyn Edison Company, who has lately returned from an extended trip abroad, taken in company with Mr. C. L. Edgar, of the Boston Edison Company, for the purpose of making a thorough inspection of British and Continental central station practice, has kindly consented to prepare a series of articles for ELECTRICITY embodying the results of his investigations.

Mr. Barstow is widely known as a progressive central station manager. Many of the ideas which he has gathered will be put into practice in the new Pearl street station of the Brooklyn company which is now building.

It is high time for central station men throughout the country to realize that the Europeans have passed us in many points, not so much perhaps in the main features of the apparatus as in details, which make either for economy or waste as they are properly or improperly arranged. With competition growing sharper each year, and with dozens and scores of cities all but ready to build municipal plants, the course of wisdom for central station men is to do everything possible to reduce the cost of current to themselves, and to lose no chance of gaining practical information, such as Mr. Barstow's articles are sure to contain. It is in this way that the municipal plant craze may be soonest disposed of, and the business of selling current at a profit be put upon a solid footing.

* * *

Figures and Words.

In another column will be found a thesis on the above subject to which we are pleased to give special prominence. It should be clipped out and pasted up in a conspicuous place in every electrical laboratory in this country.

Mathematical errors in the electrical science have been numerous, all-pervasive and hard to kill. They have delayed the progress of the art, have been the cause of many fruitless hours of laboratory research, and to-day are the direct cause of the non-success of many kinds of apparatus. Capitalists who have backed the inventions of men who are mathematicians only have invariably lost money until the services of the man who was something more than a mathematician were enlisted.

The expression, "hard-headed men who have not been educated out of their common sense," is worthy to rank with the brightest pearls of language.

It is far from our purpose to urge that mathematical formulas and deductions are useless, and should be discarded. They are essential in their proper place, but they must, in order to be of value, include every factor entering into the problem considered. In many cases deductions have been drawn from mathematical solutions involving a large number of independent variables although such a solution is an acknowledged impossibility. In others there exists a certain amount of empiricism and for the purpose of deduction they are worse than useless—they are pernicious. Having once made their appearance in a reputable technical work, they are accepted as correct by succeeding writers, and are quoted as authority for years after the practical worker has proved their fallacy.

Mr. Edison has said that in his experience whatever has been proved to be impossible by the mathematical authorities has been the easiest invention to produce.

While this is perhaps an exaggeration, more than one instance could be cited in support.

Mathematicians who have been long enough out of college to test in actual experience the deductions which they were taught to believe in as containing the very essence of truth have had their idols broken, their faith shattered, because of the mistaken applications or fatal omissions in their calculations.

While it would indeed be sacrilege to say anything "disrespectful concerning the multiplication table," it should be used as the wise physician uses his formula of drugs—with great discrimination. And as in many cases the physician renounces drugs, and recommends pure food and wholesome exercise, so in electrical work mathematics should often be laid on the shelf and common sense be given full swing.

* * *

Alternating Current Distribution.

The advantages which are offered by the alternating current for transmission over long distances are so obvious that this system has become thoroughly established in central station work in spite of the drawback which it has felt from the lack of a satisfactory motor for existing lines. At present the multiphase systems seem to point to the solution of this question, and considerable work in this field is being done both in this country and abroad. Elsewhere will be found a description of such a system which is being operated in Pittsfield, Mass., from which both lighting and power are run on the same circuits.

The motor business has grown to be a large factor in central station work and is especially desirable as it falls during the day run when the dynamos are only called upon to operate a few lamps. The load diagrams of the average central station show that the chief output of current is confined to perhaps five or six hours a day, and during the remaining time probably not over ten or fifteen per cent. of the capacity of the station is utilized and the efficiency of the system is considerably reduced.

Besides this, the distances which can be economically reached by direct currents of the pressures ordinarily used for lighting are limited by the cost of copper to five or six miles, so that to supply power by direct currents beyond that distance requires special machines and separate circuits.

The multiphase alternating current can be used for lighting alone as well as the ordinary single-phase current, and is specially adapted to power transmission from central station as this can be run on the same circuits with the lamps without introducing any serious complications.

In the plant mentioned above, the two-phase current has been chosen as the most simple of the multiphase type, and because the two outside wires of the system may be connected at the switchboard and used as one wire if it is desired to throw the circuit onto a single-phase machine.

The weight of wire necessary for this system is also considerably less than that used in the ordinary single-phase system for the same load and drop.

The transformers for lighting should be divided about evenly between the two sides of the system, but are not necessarily exactly balanced, as a difference of load does not affect the regulation. It is for this reason more easily operated and less troublesome than the three-wire system.

The present transformers in use for lighting can be used by breaking one of the connections and making connection to the third wire. Where motors are needed, a special transformer is put up with connections made to all three wires.

* * *

The Situation Up to Date. The victory of the Columbia Lamp Company at St. Louis is far-reaching in its effect on the general business. It means the breaking down of the Trust's lamp monopoly before it was fairly established.

The evidence introduced was of so conclusive a character, it seems unlikely that it will be ignored by Eastern judges when motion is made to reopen the factories which have been closed under proper bonds for the protection of the owners of the Edison patent.

Judge Hallett's decision places the independent interests in as strong a position as they have ever occupied, and with the overwhelming sentiment of the community at large in favor of dealing with independent concerns in preference to a Trust, the downfall of the Electric Trust is practically settled.

The publication of a vague and unsatisfactory statement of its condition has unsettled the confidence of its Boston backers, and General Electric's stock on Saturday last touched the lowest point since the organization of the company. With the tide of business turning steadily away from the Trust, a reduction of the dividend rate must soon be announced.

The General Electric Company will soon be compelled to assume its proper place in the field —merely that of one company among many, striving to sell its own goods. Its claims to exclusive rights are already a laughing-stock.

The outlook is bright for honest business methods, and very dark for Monopoly with its ten-year contracts.

* * *

If the money which has been spent in the attempt to sustain the Edison lamp patent had been spent in perfecting the Edison lamp, central station men and consumers would not have had so vital an interest in the production of non-infringing lamps, or in upsetting the Edison claims.

* * *

If Brother De Camp, of Philadelphia, is confronted with a municipal plant by-and-by, we wonder if he will be able to discover the reason why such a move on the part of the city became a necessity? The news from Detroit points a moral to every combine in the lighting business. It should be heeded. And the Detroit combine was fairness itself compared with the Philadelphia Trust.

Burst the hewgags, split the drums;
Lo, the day of justice comes!

* * *

The Columbia Lamp Company put up their money and made their fight, almost unaided, and against the judgment of nine out of ten men in the trade. Mr. Rhothamel led the forlorn hope, and he has won.

* * *

It will be in order now for the Buckeye Company to announce that they have resumed the manufacture of incandescent lamps and are ready to take orders and make shipments.

* * *

We salute Messrs. Peale & Packard. They held the fort like old soldiers.

* * *

Monopoly has a pain in the back.

* * *

The pirate Bernstein and Thomson-Houston lamp factories may now continue unmolested.

* * *

If Columbia lamps are lawfully made in St. Louis, why can they not be lawfully sold in New York or Philadelphia?

* * *

" O frabjous day, calloo, callay ! "

Trolley Patents Issued.

" Will Astonish the Public."

An inspired Associated Press despatch from Washington reads as follows :

"It will probably astonish the public to learn that, although thousands of trolley electric cars are in operation throughout the United States, and have been for several years, the question as to who was actually the inventor of the trolley is one which has been a subject for contention and litigation before the Patent Office for several years, and that during this period several claimants for this honor have been contesting for the issuance of patents thereon for which applications were made long ago.

"The question as to who was actually the inventor has at last been practically settled by the issuance to the Thomson-Houston Electric Company, as assignee of Chas. J. Van Depoele, of two broad foundation patents covering the trailing trolley, so-called, which is what is known in connection with electric railways as the trolley. The General Electric Company, into which the Thomson-Houston Company was merged something like a year ago, will become owners of these patents, the possession of which, with other patents upon the same device previously granted to Chas. J. Van Depoele and assigned to the Thomson-Houston Company, will practically give them control of the use of the trolley throughout the United States, and the issuance of patents to them is considered a great victory for the General Electric Company, and one from which must result increased earnings to the company."

It will indeed astonish the public when they learn that all these statements are correct. But they have not yet learned it.

It usually takes further proceedings than the *issuance* of a patent to establish fundamental claims, and still further proceedings to exact royalties.

One thing, however, that does not astonish the public is, that the General Electric people are making a desperate effort to steady up a tottering stock market.

The despatch above mentioned also states that Mr. Van Depoele " had become a comparatively rich man *through the generosity* of the Thomson-Houston Electric Company." This is, indeed, astonishing.

Trolley Magnates in Town.

John A. Seely, the head of the firm of John A. Seely & Company, railway constructors and trolley road equippers, of New York, and Edwin S. Perot, Cornelius Gallagher and James P. McQuade, of the National Construction Company, New York, who are also officers of the Norristown Passenger Railway Company, are in town to-day on business connected with the trolley.—*Norristown (Pa.) Times.*

Detroit Electrical Works.

Final Attempt to Raise Money.

The secretary of the Detroit Electrical Works, Mr. Joseph E. Lockwood, has sent out to the stockholders a detailed statement of the present financial status of the company, and suggesting three or four plans for raising money.

Our advices from Detroit are to the effect that nothing short of a receivership can re-establish confidence and pull the company out of the hole into which it has been dragged by the incompetency of the present management.

Appreciative Employees.

F. S. Terry Banqueted.

A very pleasant surprise was given to Mr. F. S. Terry, of the Ansonia Electric Company, at Chicago, on the 19th inst., by the heads of the various departments under him. The surprise consisted in a banquet at the Union League Club Rooms and the presentation of a very handsome gold embossed morocco autograph album, containing the individual signatures of the donors.

The Hon. George B. Shaw presided as toastmaster, and in a very neat speech presented the gift.

The event was occasioned by Mr. Terry informing his employees that each one would be given two weeks vacation and every Saturday afternoon to see the World's Fair.

Among the invited guests were John R. Fletcher, J. B. Wallace and B. F. Freist.

The Trust in Philadelphia.

The Legislative Committee appointed to investigate the Electric Light Trust in Philadelphia was in session last week, and proceeded with the examination of witnesses. All the members of the committee were present, Major Samuel A. Losch, of Schuylkill County, presiding.

There were many interesting developments in the testimony, showing how companies had been frozen out and the city territory parcelled out to avoid all competition.

The committee has not yet completed its report.

The Chicago Consolidation.

The Chicago Edison Company and the Chicago Arc Light and Power Company have taken formal legal action to confirm the consolidation of the two companies. The consolidation was practically concluded some three months ago. The new company will be known as the Chicago Edison Company and will have the same officers as the old company by the same name, but will be managed by C. H. Wilmerding, former manager of the Chicago Arc Light and Power Company.

A Clean Bill of Health.

The Statement Was Correct.

(Boston Special in Wall Street Papers.)

" In view of the appearance of a *scarlet-colored pamphlet* on General Electric written in the interest of bears on the property, it may be well to state that some time ago the board of directors constituted Messrs. Henry L. Higginson and T. Jefferson Coolidge, Jr , of Boston, and H. McK. Twombly and C. H. Coster, of New York, a committee on accounts, and it is this committee that has had full charge of the General Electric accounting, and they have devoted a great deal of their time to the subject and have placed the General Electric bookkeeping upon a most conservative basis."

The case must indeed be desperate when Mr. Coffin will allow a statement of this nature to be made with official sanction.

The time was when Boston believed Mr. Coffin. How long is it since it became necessary for four of his business associates to guarantee that Mr. Coffin had told the truth ?

Grosvenor P. Lowrey.

Grosvenor Porter Lowrey, senior member of the firm of Lowrey, Stone & Auerlach, was striken with apoplexy shortly after 6 o'clock on Thursday night last at his home, 121 Madison avenue, New York City, and died at 9:30 o'clock that night. Mr. Lowrey came of an old Dutch family, and was born in North Egremont, Mass. After receiving a common school education, he studied law under Andrew H. Reeder, at Lafayette College, and was admitted to the bar in 1854. Kansas was made a Territory in 1854, and Mr. Reeder was appointed its first Governor by President Pierce. Mr. Lowrey became Gov. Reeder's private secretary, and accompanied him to Kansas. It was at the beginning of the struggle which resulted in Kansas becoming a free State. Gov. Reeder and Mr. Lowrey were Free State men. During the temporary triumph of their opponents they and many other Free State men were indicted for treason, and they fled from the State in 1856. Returning to the East, Mr. Lowrey engaged actively in the support of John C. Fremont, then running for the Presidency. During the session of the New York Legislature in 1856-7 he was the Albany correspondent of the New York *Evening Post*, and in the following spring he settled in this city as a lawyer, entering the firm of Porter, Lowrey, Soren & Stone. Ex-Judge John K. Porter was the head of this firm for many years.

In the course of his career Mr. Lowrey had been the legal adviser of many great corporations, among them being Wells, Fargo & Company, the Western Union Telegraph Company, the Gilbert Elevated Railroad and its successor, the Metropolitan Elevated Railroad Company, the B. & O. Railroad Company, the B. & O. Telegraph Company and the United States Express Company. He became acquainted with T. A. Edison through his connection with the Western Union Company.

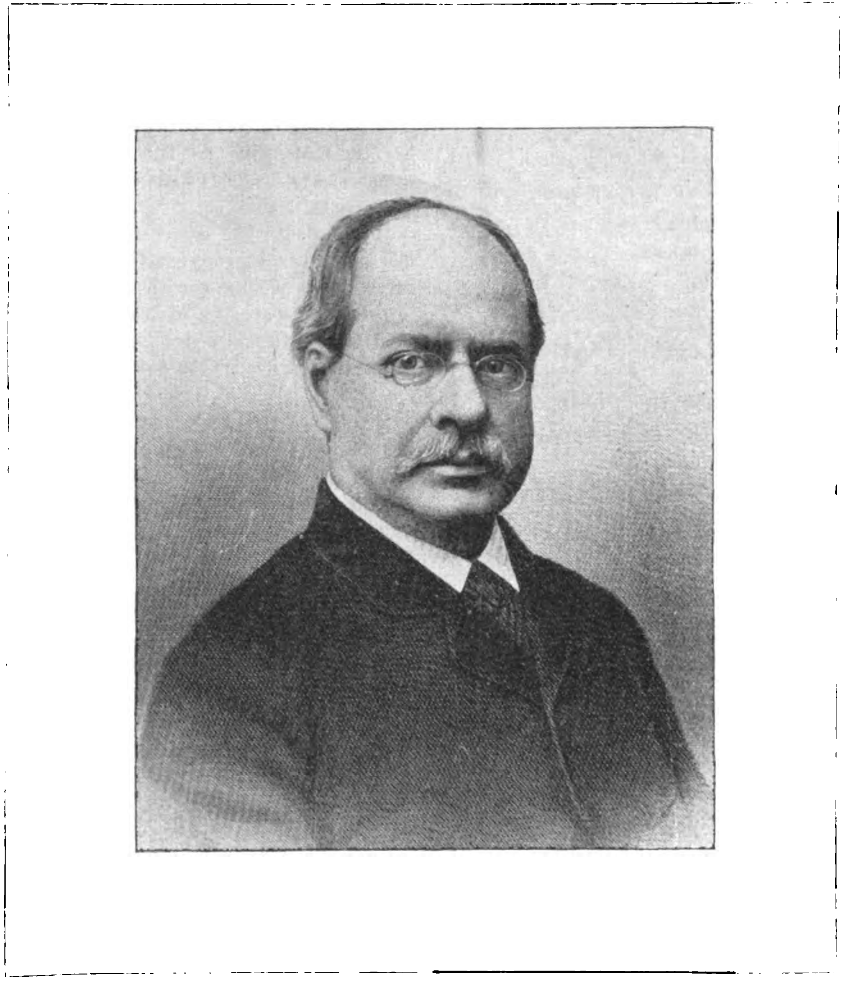
He was associated with Allan G. Thurman as counsel for the United States Government in its unsuccessful effort to break the Bell telephone monopoly's patents a few years ago, and did all the legal work in connection with the establishment of the New York City and Northern Railroad.

He wrote considerably upon professional subjects. One of his pamphlets, "English Neutrality," relating to the Alabama and other Confederate cruisers built in English ports, was the first of the inquiries into British responsibility in this matter which led to the award of damages.

The news of his death was announced in the U. S. Circuit Court by Elihu Root, and the court adjourned in respect to his memory, as did also several of the other courts in session in this city.

Mr. Lowrey was one of the original incorporators of the Edison Electric Light Company, in 1878, and a member of the first Board of Directors. He was up to the day of his death the mainstay of the Edison interests in their legal proceedings, and had won several strongly contested cases involving the validity of the Edison patents. His strength as an advocate in these cases was perhaps due, more than to any other reason, to his unwavering faith in Mr. Edison and his work.

Mr. Lowrey was a man of charming personality in social life, and maintained not only the respect but the admiration of those who were honored by association with him.



Grosvenor P. Lowrey.

The Rutland Electric Light Company, of Rutland, Vt., has secured a perpetual injunction restraining the Marble City Company from erecting its poles or stringing its wires so as to interfere in any manner with the poles and wires of the plaintiff company. The decree of the court, which also provides for the appointment of a master to determine the amount of damage sustained by the Rutland Electric Light Company by the Marble City Company's infringement on their rights and property, has been confirmed, with an order for removal of all conflicting wires and poles of the Marble City Company, by the Supreme Court of Vermont, Chief Justice James M. Tyler presiding.

Figures and Words.

(*From the New York Sun.*)

Arithmetic will have its praises chanted in a Mathematic Congress at Chicago louder than ever before in this country. With united breath the International Statistical Association and the American Economic Association will hold sessions for seven days, with many foreign statisticians of eminence to help them. Much will be said by these men of figures as to the ways in which statistics should be gathered. Albeit we should say nothing disrespectful concerning the multiplication table, we trust that as to the common sense needful in using that instrument something will be spoken in this notable convocation.

Once upon a time there dwelt in Yorkshire a schoolmaster under whose care was a boy apparently so dull as to be the butt of his class. In the teasing of that boy the master was mean enough to join. Calling the urchin to him one morning he said: "Tommy Jones, I have a very simple question in arithmetic for you, and dull as you are I think you can answer it." "Yes, please, sir." "At the baker's near by they sell penny buns, don't they?" "Yes, please, sir." "How much would two of them come to?" "Dunno, please, sir." "You don't know, you little donkey; aren't two penny buns always tuppence?" "No please, sir; they—sell—'em—two—for—three—ha'pence—when—the're—stale." And the flogging which threatened Tommy Jones was omitted.

If in regard to a minor article of diet it be necessary to take account in one's arithmetic of a perturbing fact such as staleness, how much more needful is it that we should proceed cautiously, circumspectly, tentatively, when the objects of examination are the perplexities of finance, commerce, and social betterment? The official statistician of Scotland found the death rate among unmarried men to be exceedingly high. Therefore, said he, arguing for the establishment of families, bachelorhood is more destructive to life than the most insalubrious trades, or than residence in the most unwholesome houses or districts. This man's heart was in the right place, no doubt, but his eyes saw only a little of the evidence before him. He failed to observe that men of extremely bad health or habits, or sunk in direst poverty, rarely aspire to the wedded state; and that, if one courts a girl, he is exposed to a very natural rejection. Their liability to premature death is the cause and not the consequence of their singleness.

Pitfalls of another sort spread before him who holds figures so close to his eyes that he cannot see facts a little further off.

To come to the case of honest labor: we are told by the census returns, and truly, that wages are higher now than a generation ago, while in the main a dollar buys as much as it did then. But as to how much more the workman wants to-day than he did thirty or forty years ago, we are uninformed. What schedule, however ample in width or minute in interrogation, can seize upon all the facts required to prove or disprove, statistically, the policy of protection or prohibition? Mr. Carroll D. Wright, Commissioner of Labor at Washington, has seen the task attempted many times; he is fond of saying: "Figures won't lie, but liars will figure;" and no less a man than the Rev. Edward Everett Hale is wont to give the noun, lies, a grammatical comparison thus: "Positive, lies; comparative, damned lies; superlative, statistics." Because calculation is legitimately applied in many ways, let us not imagine its conquered empire to be universal.

As with figures, so with words. Speech is one of the faculties which difference man from brute; it is the handmaid of reason. And yet language brings with it liability to a copious source of error; we are ever prone to overestimate the proportion of thought which can be put into words.

Among hard-headed men who have not been educated out of their common sense there has always been a conviction that the logicians overrate the importance of what can be definitely argued about; that, as theorists can never take account of all the facts, no theory should be held with other than a loose hand. Such men may not be learned, but they are wise, for they never gloss over a difficulty with a verbal simplification. They may carry in their memories a scanty store of the guesses and assumptions of other men, but they allow for their ignorance, and so judge much more soundly than if they supposed part of the evidence in the case to be the whole. Something of a spirit of restraint is felt in every court of justice worthy of the name. To law is added equity; and jurists who declare legal procedure in important fields to be beyond improvement well know that there remains the old difficulty of getting truly at the facts. In endeavoring to probe into the play of motive the just Judge finds that motive has its chemistry as well as its mechanics. There are times and places when and where two and two make not four, but five and a quarter.

Investigators of the resources of the human brain are constantly coming upon proof that the wealth which the mind consciously holds is a trifle compared with the treasures it unconsciously possesses. The one is an islet in the sea, the other broad and substantial as an engirdled continent. Science never does worthier service than where, as here, it points beyond the horizon of the known to the depths where words and figures lose themselves in the welter of mystery. Then does she become the mother of a reverence profounder than was ever inspired by microscope or analysis; for she proclaims that beyond their range on every hand stretches the Infinite.

General Electric's First Annual Report.

SECOND PAPER.

A Comparison Showing the Net Results of Eight Months' Business from the Company's Own Figures.

On May 31, 1892, the General Electric Company made application to the New York Stock Exchange to list its common and preferred stock.

A statement was filed on that date, signed by C. A. Coffin, president, and A. S. Beves, treasurer, presumably showing the condition of the Edison General, Thomson-Houston, and Thomson-Houston International Companies at the time of their consolidation into the General Electric Company. These three companies are designated in the present annual report of the General Electric Company as the Underlying Companies.

The annual statement, printed in ELECTRICITY last week, did not show the volume of business for the eight months, or the running expenses. The flat assertion appears, however, that the net profits of the business for the eight months were $3,356,593.10.

A comparison of the two statements, the one filed at the Stock Exchange on the underlying companies May 31, 1892, and the annual statement of the General Electric, shows a totally different result.

Such comparison is the only method for arriving at the actual results.

The following table shows the assets and liabilities of the three underlying companies as they appeared on May 31, 1892, and of the General Electric Company January 31, 1893. The table is compiled from the company's own figures on the different dates mentioned.

This comparison and its deductions are correct.

	Reports of Edison General, T.-H. and T.-H. Int. Cos. filed at N. Y. Stock Exchange, May 31, 1892.		Report of General Electric Co. published Jan. 31, 1893.

Surplus after paying dividends		$9,278,596.51		$1,024,954.59	Dec. $8,253,641.95

Decrease in surplus in 8 months	**$8,253,641.95**
Less dividends and interest paid	**2,331,638.51**
Net decrease in surplus for 8 months	**$5,922,003.44**

Items marked *I* taken together represent the investment account of $18,262,060.24.

We defy the controller of the company, or the Accounting Committee, to show any other result from their own figures.

The comparison was made by an accountant of high standing in his profession, a man with no interest in the respective companies nor in ELECTRICITY.

Its accuracy cannot be denied.

In view of this condition of affairs, it is pertinent to inquire, Has the General Electric Company been paying dividends from the sale of stock?

In the Stock Exchange statement the Thomson-Houston patents are valued at **$838,854.29**. In the annual report these same patents are carried at **$3,389,352.07**. Have they increased three millions in value in eight months?

The General Electric Company commenced business May 31, 1892, with $100,000 in cash, of which they paid for expenses $215 and for franchise tax $25,000, leaving cash on hand May 31, 1892, $74,785 and $33,871,500 in stocks of the Edison and Thomson-Houston Companies, for which stock of the General Electric Company was issued.

Now, in the statement of the underlying companies there appear two items, aggregating $16,301,809.76, which, according to the report, were made up of moneys advanced to the Edison and Thomson-Houston Companies and of an arbitrary guarantee against those companies' notes. In other words, this sum of $16,301,809.76 was at one time a liability of the two underlying companies. This liability, so the report states, was wiped out by the General Electric Company, and the amount was deducted from the purchase price of the two underlying companies. How was it wiped out? With only $74,785 of actual cash on hand, how were over sixteen millions of debts paid?

This is a system of bookkeeping which needs explanation.

"The Windsor Hotel party that has been successful in its operations in the general market, has now directed its attention to General Electric, and claims that the stock will be 'put through its facings,' the same as have all others that have shown vulnerability. The buying by Drexel, Morgan & Company apparently has availed nothing, and General Electric, it is said, will sell at 75 this summer.—*N. Y. Mercury.*

Personal.

Mr. H. J. Wendorff, who has been for a long time at the head of the storerooms of the Brush Company, Cleveland, has been appointed Purchasing Agent in place of Mr. L. W. Bradley, who resigned some time ago.

Mr. Wm. Hazelton, 3d, who has been connected with the Short Electric Railway Company for some years, and whose headquarters are in Cleveland, Ohio, has been appointed the Assistant General Manager of the company.

Mr. W. A. Jackson has been chosen as President of the Electric Lighting Commission of Detroit.

Mr. Morris Mead, Superintendent of the Bureau of Electricity of Pittsburg, has received the appointment from Director-General Davis as Assistant Chief of the Electrical Department of the World's Fair.

Dr. F. A. C. Perrine, of Boston, was a visitor in New York last week.

Electric Lighting on French Railways.

The Northern Railway of Paris has recently adopted electric lighting on some of its cars, and twenty-seven first, second and third class coaches have been wired for incandescent lamps. The current is supplied from a battery of accumulators placed under each car, each cell having a capacity of 113 ampere hours. The lamps used consume three watts per candle power and this efficiency limits their life to about 300 hours. They are 30 volt lamps of 10, 8 and 6 candle power according to the cars on which they are used.

The current is carried to the lamps by means of insulated cables and connected by three zinc clips, and switches are attached at the end of the cars for controlling the lights and making connections for charging the accumulators.

The cost of fitting up the coaches is given at $150 and the experiments so far have shown about 10 per cent. less expense than was the case with the oil lamps formerly used.

A Transformation.

Preparations have been completed by which the Telluride, Col., Electric Light Company will hereafter receive power from the San Miguel Consolidated Light Company from their power station at Rives, a distance of twelve miles.

This is perhaps the first instance on record where a Westinghouse system has been called upon to furnish current to an Edison system and with satisfactory results.

"Herr Heinrich Goebel, hoch, hoiero!"
J. W. ORR N.Y.

THE INDEPENDENT BIRD.

The Columbia Lamp Co. Wins.

Goebel's Claims More Fully Established.

An Injunction Denied.

Judge Hallett, of the United States Circuit Court, has refused to grant an injunction against the Columbia Lamp Company at St. Louis.

The final hearing in the suit for a preliminary injunction, brought by the Edison Electric Light Company et al. vs. the Columbia Incandescent Lamp Company, was begun on April 11th and closed on the 14th.

The Columbia Company contended for the prior claims of Henry Goebel, the defense which was first introduced by the Beacon Company at Boston, and with which our readers are generally familiar.

The Beacon Company lost their case through their inability for lack of time to fully substantiate the claims made as to the dates when certain lamps were made by Goebel.

The Columbia Company, with the same able counsel, Messrs. Witter & Kenyon of this city, have worked industriously since the Boston case closed, and seem to have established beyond question the identity of the various exhibits, and to have proved that Goebel's lamps were of sufficient merit to invalidate the Edison lamp patent.

Judge Hallett has held that the evidence is "sufficient probably to invalidate the patent."

The decision is one of supreme importance at this time, and is a thorough and complete victory for the independent element in the trade.

There will be no lamp monopoly.

No one will be compelled in order to get lamps to buy his entire apparatus of the General Electric Company.

Central station men can once again use their own judgment in the purchase of lamps. They will no longer be forced to buy the poorest lamp on the market.

The conclusive proof introduced by the Columbia Company will no doubt be introduced successfully to re-open some of the closed factories, and there will at least be no further interference with the Ohio companies and others not proceeded against so far.

We congratulate the Columbia Company and the trade at large on the result, and the brighter outlook it has produced.

Following is Judge Hallett's decision in full:

THE DECISION.

In the Circuit Court of the United States for the Eastern Division of the Eastern Judicial District of Missouri.

Edison Electric Light Company et al. vs. Columbia Incandescent Lamp Company et al.

Complainants allege infringement of letters patent, No. 223,898, issued to Thomas A. Edison, January 27, 1880, for an improved electric lamp. This patent came under the consideration of the Circuit Court of the Southern District of New York in the case of the Edison Electric Light Company against the United States Electric Lighting Company (47 Fed. Rep. 454), and was held to be for a lamp "consisting essentially of a filamentary carbon burner, hermetically sealed in a glass vacuum chamber." So understood, it is the incandescent lamp in common use, and no question is presented in this record as to the character of respondents' manufacture. The defence to the bill and to the motion for preliminary injunction now under consideration is want of novelty in the Edison patent. Respondents aver that an incandescent lamp, different in form, but in all essential features the same as that now in general use, was made as early as 1854 by Henry Goebel, of New York City, and that it was used by him in various ways and at different times for many years thereafter. It will not be necessary to describe this lamp at length, as it has the same constituents as the Edison lamp. We are at present more concerned with the struggle between the contending forces on the one side to maintain and on the other to disprove the existence and use of the lamp anterior to the date of the Edison invention. A large mass of testimony in the form of affidavits is offered by each party on the question of fact, which to consider at length would be a tiresome and unprofitable task.

The principal objection urged by complainant against the Goebel invention is that it has an impossible date; no man could make it in the time and manner assigned to it; the incandescent lamp is the product of several auxiliary arts not likely to fall within the compass of a single mind; as an achievement of science the lamp is a matter of progressive steps, some of which must be made by the world at large before others can be taken by any one. This is no more than to say that no man can outrun his competitors to any great length in the field of scientific investigation—a proposition which has no support in reason or experience. There seems to be no reason for saying that Goebel could not reach in 1854 a point attained by Edison in 1879 unless, as was said by the dissenting justices in the telephone case: "It is regarded as incredible that so great a discovery should have been made by the plain mechanic and not by an eminent scientist and inventor."

In so far, however, as it may be shown that the methods adopted by Goebel were not equal to the results obtained, the evidence should receive the most careful consideration. On this point it appears that Goebel has recently made several lamps of the form used with the material and tools formerly used by him. These lamps were tested by men of experience and skill in such matters, and they were found to be reasonably effective. They are not so good as the lamps in common use, but they can be operated, and they give reasonable service in time and capacity of light. So that in this way we have prima facie proof of Goebel's ability to make lamps in the way he claims to have made them before the time of Edison's invention.

It is said that Goebel is involved in contradictions and misstatements of fact, due to the lapsing memory of old age or to untruthfulness. Be it so; he does not appear to be an adventurer or an impostor. It is not reasonable to believe that he made the story related in his affidavit and did not make the lamp he has described. Whatever may be said as to Goebel's veracity, he is supported at many points by witnesses of good repute, who speak with precision and apparently with deliberation. As already suggested, it is not necessary or profitable to go over the testimony at length with a view to determine the relative value and weight of every part. It is enough to say that there is a fair preponderance of testimony in support of the Goebel claim.

There is not the measure of proof demanded by defendant's counsel, who maintain that the court should require proof of the fact beyond reasonable doubt. This degree of certainty is not often attained upon testimony in the form of affidavits, where the issue is contested, and it is not reasonable to demand such certainty as to the defense. Complainants must show a clear right in support of a preliminary writ, and a defense which puts the case in doubt is sufficient to defeat the application. It is also contended that the decree of the Circuit Court of New York against the United States Electric Lighting Company sustaining the patent, which decree has been confirmed in the Court of Appeals of the Second Circuit, is conclusive of complainant's right to the writ for which they now ask. No doubt is entertained as to the conclusive effect of that decree here and elsewhere as to all matters in issue in that cause. For although respondent was not a party to that litigation, the court would not on a preliminary motion consider any matter which passed to judgment in that suit. The Goebel defense was not made in that suit, and therefore the case has not the authority on this motion which has been ascribed to it. Another suit by the complainants against the Beacon Vacuum Pump and Electrical Company, in the Circuit Court for the District of Massachusetts, is in a different attitude. In that suit the Goebel defense was made, and upon motion for preliminary injunction recently heard and allowed it was overruled. It is contended that the ruling in that case should be recognized and followed as a precedent in respect to the present motion, and perhaps if the issue, the testimony and the situation of the parties appeared to be the same in both cases such result might follow, more from the persuasive effect of the opinion of another court on the same matter than from any notion of authority ascribed for such opinion. In courts of equal jurisdiction proceeding concurrently in the investigation of the same subject, the right and duty of each to exercise independent judgment cannot be denied. That they should in the end reach the same result is greatly to be desired, but one cannot become an echo to the other for that praiseworthy purpose. In this instance the consequences to flow from diverse opinions are not regarded as serious. In the Massachusetts Circuit, and here as well, the motion is interlocutory; and in each case the ruling may well enough stand upon the situation of the parties. And we have much additional testimony to that upon which the court acted in the

Beacon case, so that upon all points I do not feel compelled to accept the opinion of the court in that case.

The ruling of the court, however, in the Beacon case suggests the propriety of taking security from respondents for observing the decree in case complainants shall ultimately prevail in this suit. There are other considerations which should have weight in that direction. It was suggested by complainants' counsel that respondent is a concern of small capital, and that it was made so with intent to avoid responsibility in respect to the infringement now alleged against it. This was not denied and I suppose we may take it to be true. The retort was in the form of a charge against complainant that it used its monopoly of electric lamps to control the sale of all kinds of electric machinery and apparatus. This charge also passed without denial, and it is not difficult to conceive of circumstances in which it would be necessary to ascertain whether it is true. Referring only to the charge against respondent of insufficient capital and assets, the duty of the court is plain to provide for the contingency of a decision against it. I need not refer to the possible effect of cross-examination in the case of a multitude of witnesses. What now seems plain enough may altogether disappear, and new facts may come to the surface under that crucial test.

The injunction will, therefore, be refused if the respondents will give a bond in the sum of $20,000 conditioned for the payment of such sums (it any) as may be decreed in favor of complainants on the final hearing of this cause. The bond to be filed with the clerk of the court, and to be approved by the clerk, or by a judge of the court within twenty days from this day.

HIS NAME WAS MONOPOLY BEFORE HE WAS LICKED.

Detroit Lighting Matters.

Practical Discussion Before the Council Committee.

A Municipal Plant Probable.

The committee on public lighting of the city of Detroit recently met to consider the question of a municipal plant. Three members of the new lighting commission, Messrs. Hudson, Butzel and Jackson, attended the meeting, as did also Mayor Pingree, Aldermen Vernor and Scovel, Frank B. Rae and the representatives of several large electric companies.

Mr. Rae made some explanations in regard to his estimates,* and a candid reply to the criticisms of ELECTRICITY, which leaves nothing more to be said on that score:

"The figures were obtained from manufacturers of apparatus, and a number of letters have been written to the Mayor and several to myself, stating that the manufacturers of apparatus are willing to undertake the construction, both of the steam plant and of the electrical plant, under this estimate. In the cost of maintenance, by advice of some of the gentlemen downstairs, the question of taxes and cost of water were left out. They were left out upon advice, because it was not at all probable that the taxes upon the present plant will be lost to the city, and the cost of water in the operation of a plant of this kind would cost the city nothing in any event. If the plant were to be located on the water front, as I think it should be, the water would be entirely free to them, as it would be to any other manufactory so located. If they took water from the city, I presume they would hardly be chargeable with any rate for that—simply supplying it from pumps which the city maintains at one station instead of those they would maintain at another station."

The Detroit Electric Light and Power Company did not appear by representative, but sent in a communication, closing as follows:

"Our experience of three years in public lighting has been costly. We know from experience what it takes to run a plant in Detroit, but it appears that the guess of men interested in foisting a plant on the city has been taken as evidence, and cold facts entirely ignored. Hence we deem it a waste of time to attempt an explanation before your honorable committee."

Letters from Messrs. Campbell & Zell and Fairbanks, Morse & Company, of Chicago, were read, in which both firms agreed to undertake the contract for the steam plant within Mr. Rae's estimates.

Alderman Hudson thought Mr. Rae's estimate for the purchase of real estate too low. Discussion brought out the fact that the city might build on its own land.

Mr. Young, representing the Western Electric Company, said that he had looked over the estimates prepared by Mr. Rae and would have no hesitation in furnishing a first class plant, up to standard in every way, for the amount stated in the estimate.

Mr. Cook, a representative of the Westinghouse Company, said:

"The class of machinery which we manufacture would be such as is covered by his estimates Nos. 1 and 2, and I can say that his estimates for the apparatus are certainly ample. As far as the cost of maintenance goes, it can be shaded. We can furnish lamps which will burn for three nights with one trimming. With that class of lamps about a dozen or thirteen men would take care of the trimming. I should consider Mr. Rae's estimates all right."

Mr. Long, representing Westinghouse, Church, Kerr & Company, stated that his company had done a great deal of work in Detroit, and knew about the expenses of doing the work there in the way of masonry and contingent work outside of the mere cost of the apparatus. He was free to say that Mr. Rae's estimates fully cover the very best class of work that could possibly be put in

At a meeting of Council on the 19th, the Commission was authorized to advertise for bids for a complete plant, and also to advertise for bids for lighting the city on a three-year contract by the present system.

A Successful Storage Battery.

Trial of the Waddell-Entz Company's Apparatus on the Second Avenue Line.

A Satisfactory Exhibition.

The first public exhibition of the street-railway storage battery apparatus of the Waddell-Entz Company took place on the Second Avenue line, this city, on Friday, April 21.

The test derived importance from the fact that ten cars similarly equipped are stored at one of the stations of the Second Avenue Company, and also for the reason that it is proposed to operate the road altogether with electric cars of the same design.

The claims of the inventors seem to be fully borne out by this test. In the first place, there was no buzzing, so common in many storage-battery cars; the action of the motors was almost noiseless. Another feature was the extreme ease with which the cars could be stopped. No brake was used, there being simply a reversal of the motor. The cars can be brought to a standstill within the length of the car from a speed of fourteen miles an hour. In this sudden stopping there is no waste of power. On the contrary, the momentum converts the motor into a dynamo, and there is a positive storing up of energy. The car can be run backward as well as forward.

The cars can run thirty miles without re-charging the batteries. The batteries themselves weigh but 2,000 pounds each, two being placed on each car.

The electric plant which has just been completed at 127th street and Second avenue consists of two 100-horse-power safety boilers, two automatic engines of 75-horse power, and two 75-horse power dynamos. From the dynamos the current is led by switchboards on the battery floors. On the second floor is a large electric crane. By a touch two batteries weighing 4,000 pounds are lifted and then lowered to the first floor, where they are transferred to the cars. The old batteries can be removed and newly charged ones put in the cars within two minutes.

The system is the invention of the Waddell-Entz Electric Company, and the entire plant, including dynamos, motors, etc., was made at their works at Bridgeport, Conn. The motors and portions of the apparatus are similar to those put in many public buildings throughout the country.

It is expected that by June 1 the Second Avenue line from Ninety-sixth street north will be exclusively operated by electric cars, and a little later the system will be adopted for the entire line.

The car left the power house at 127th street and Second avenue at 4:27 P. M., and made the run to 96th street with one trailer. The latter was taken off there, and the return trip was made at the rate of ten miles an hour.

In addition to the representatives of the electrical and daily papers, there were present Mr. George S. Hart, the president, and other officials of the Second Avenue road; Mr. Skitt, superintendent of the Fourth Avenue line; Messrs. Knauth, Waddell, Entz, Foot, Machado and Whitman of the Waddell-Entz Company, and several gentlemen from other cities.

Electrical men and the public generally will await further developments in regard to this system with a great deal of interest.

World's Fair Notes.

Two of the five coronas which are to be the principal feature in lighting the large Manufacturing Building were tried for the first time last Wednesday. The initial test was a satisfactory one in every respect, and it confirmed the judgment of the engineers engaged in the work as regards the number of lights for each circle and also the height to which coronas should be elevated above the floor to give an equitable distribution of light.

The official exhibit of the German Government has arrived and is being installed under the direction of Wilhelm Dohn, who formerly occupied the position of secretary of the chief Post Office of Germany. The exhibit will consist of models of the apparatus, both telephone and telegraph, which has been used since the introduction of these instruments into the Post Office service and up to the present time.

A novel exhibit is to be made in the Electricity Building by a Parisian company, consisting of a night scene on Champs Elysee. The miniature thoroughfare will be brilliantly illuminated by small incandescent lamps, and a number of small automatic figures will be introduced which have never before been exhibited in this country.

The space formerly assigned to the Detroit Electrical Works in the Electricity Building has been given to the Westinghouse Electric Company, in which they will be able to make a more creditable display of their apparatus.

The first serious accident which can be credited to the electrical apparatus used at the World's Fair grounds occurred last week. Walter Lanhan, an electric wireman, while engaged in fixing the wires in a conduit, carelessly touched one of the main feeders and was instantly killed.

Among the standing committees announced by President Higinbotham, to act during the coming year, the following gentlemen were named on Electricity: R. C. Clowry, chairman; C. K. G. Billings, C. H. Wacker, C. L. Hutchinson, Mark L. Crawford.

---

*See ELECTRICITY, Vol. IV, No. 12, p. 162.

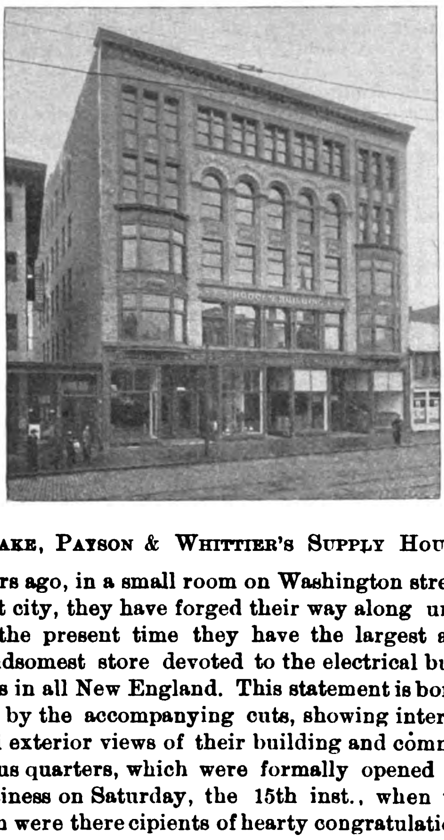
A Successful Trio.

Drake, Payson and Whittier.

Three years ago a trio of young men formed a partnership and went into the business of electrical and constructing engineering in the city of Providence, R. I. They were possessed of ability, experience and aptitude; these, combined with a large amount of energy, push and determination, well fitted them for entertaining the assurance that they were certain to achieve success in their business. They have already achieved a full measure of prosperity, and this article is an outline of what they are doing to increase their business.

Each member of this trio enjoys a wide circle of acquaintance in the State of Rhode Island, and it has always been a pleasure to friends and neighbors alike to encourage these young men by entrusting to them contracts, both large and small, knowing that the work would invariably be well done; and first class work, combined with fair and square dealings, is the secret of all they have accomplished.

The men we thus write of constitute the firm of Drake, Payson & Whittier, constructing electrical engineers and dealers in all kinds of electrical supplies, Providence, R. I.



DRAKE, PAYSON & WHITTIER'S SUPPLY HOUSE.

Commencing business, as we have stated, three years ago, in a small room on Washington street, that city, they have forged their way along until at the present time they have the largest and handsomest store devoted to the electrical business in all New England. This statement is borne out by the accompanying cuts, showing interior and exterior views of their building and commodious quarters, which were formally opened for business on Saturday, the 15th inst., when the firm were the recipients of hearty congratulations from friends, neighbors and customers from New York and all parts of New England.

The building this firm occupies is known as the Hodges Block, being 170-172 Weyhosset street. Here, in the basement, is stored an immense stock of lighting and railway supplies of every conceivable description. Here, too, is the brass finishing department and factory proper. At the remote back of the basement are two 150 H. P. boilers to be used for operating an isolated plant for lighting the entire square of which the Hodges Building forms part.

The ground or street floor is the show and sales room, which is, without doubt, the largest, handsomest and best lighted electrical salesroom in New England. It has a double front, the show windows of immense panes of plate glass being splendidly adapted for displaying apparatus to great advantage.

On entering the double doors the entire right section of the room is seen to be devoted to electrical supplies in general, consisting of bells, push buttons, annunciators, battery cells, carbons, zincs, shades, porcelain goods and electric heaters. In the window on this side are displayed the lighter goods, such as incandescent lamps, globes, wall brackets, push buttons, etc. Reaching along the floor are handsome counters and glass show cases, all filled with choice goods, while the wall is hidden away behind rows upon rows of shelves, drawers and lockers, filled with electrical merchandise.

The left side of the room accommodates, from the ceiling, a large and handsome display of gas, electric and combination fixtures of most artistic design and finish, many of them being selected from the stocks of the Mitchell, Vance Company of New York, who enjoy so wide a reputation for high grade goods of this character.

Extending right along the wall of this section has been erected a switchboard fully equipped with switches, cut-outs, rheostats, lightning arresters and other controlling devices, coupled up with dynamos and motors, installed on a raised platform in position for running at will, that intending purchasers may have actual demonstration of the working of the apparatus or machine they contemplate buying.

At the opening there were no less than fourteen dynamos and motors in position, ranging from a 100-light United States dynamo belted to a 15 H. P. Eddy motor, down to a $\frac{1}{8}$-inch H. P. motor, Eddy type, the display including Eddy, Thomson-Houston, United States and other machines.

Over the switchboard was arranged a handsome display of fan motors including the Meston alternating motor, Perret, Holtzer-Cabot and Clyde types, also some Eddy 500 volt fan motors—altogether making a handsome display and with enough variety for the most fastidious buyer to select from.

Towards the further end of the room on the left side has been built and appropriately fitted up a large dark room, from the ceiling and walls of which are suspended sample brackets and electroliers of most chaste and elegant design. The room is wired and equipped with switches and cut-outs, so that when a purchaser desires to see what will be the effect of the lighting to be done by the fixtures he is about to invest in, he can step into this dark room and have current turned on at once, so there need be no disappointment after he gets his house equipped.

Down the centre of the store are ranged handsome and massive show stands on which are displayed an endless variety of etched, plain and tinted glass globes, shades and reflectors, chiefly made by the well known Phœnix Glass Company, Pittsburg.

The accountant's office, bookkeeper's room and private offices of the principals occupy the rear end of the store, being partitioned off from the show room by polished partition walls, the various offices being comfortably furnished and equipped with all modern conveniences. This floor is 123 feet long by 30 feet wide.

As we have already stated, the formal opening of these new quarters took place on Saturday, April 15, and notwithstanding the down-pour of cold rain which fell all day long, the opening was a thorough success.

About 2,000 invitations of a unique electrical character were sent out for the housewarming; and judging from the unending stream of callers and the crowds that thronged the store, took possession of the offices and struggled to look into the mysteries and beauties of the dark room, it was clear that most of the two thousand invitations were accepted.

The handsome plate glass windows were made doubly attractive by having their sills covered with green plush carpets, on which were placed pots containing tropical palms and other beautiful exotics. The floral display also included a magnificent design of a horseshoe at the base of which was the word "Success," from Pettingell-Andrews Company, Boston; another one with the letters "D. P. & W." was presented by the employees of the firm as an expression of hearty good wishes for the continued and increased prosperity of their employers. There were other floral presents in addition.

The other window contained a miniature engine of the Greene type, which was belted to a $\frac{1}{2}$-inch H. P. Eddy motor.

As the shades of evening descended all the lights in the big store were turned on with most brilliant results, for everybody was attracted by the unusual brilliancy, and while inside the hosts of invited guests leisurely strolled round examining the innumerable devices and having their various uses and methods of working explained to them, the crowds on the sidewalk took in the gay and brilliant sight with astonishment, surprise and evident pleasure.

Among the visitors who had come from near and far to extend congratulations were representative electrical men from New York, Boston, Hartford, Windsor, Bridgeport, Ansonia, Providence, Worcester, Springfield—in fact from all over New England, including many of the leading citizens of Providence. During the evening light refreshments were served, and before the hour arrived for closing the informal reception the air throughout the large building became redolent with the aromas from innumerable choice Havanas.

The day was indeed a red letter day for Messrs. Drake, Payson & Whittier. These young men have not only deserved success, they have achieved it; and now with their large and handsome supply store, many good contracts on their books, many more pending, and the best wishes of every one to encourage them, they have settled down to do profitable work.

Bids Wanted.

The Chester Light, Water and Ice Company is now receiving bids on a Central Lighting Station, to be constructed at once at Chester, Illinois. Proposals on the entire work, or any part of it, will be received until May 15, by Wm. H. Bryan, Mechanical and Electrical Engineer, 56 Turner Building, St. Louis, where plans and specifications may be seen. The plant will consist of one 35 light arc machine and two 500 light, 2,000 volt alternators, with engines, boilers, etc.

General News.

What is Going on in the Electrical World.

Winchester, Ill.—The electric light plant in this place was destroyed by fire on the 13th inst. Loss $5,000.

Reynoldsville, Pa.—The people here are discussing the question of purchasing an electric light plant for the town.

Norwalk, Ohio—A company is being formed here to manufacture a new electric heater, the invention of W. J. Bowen.

Waukegan, Ill.—An electric railway to connect Waukegan with South Waukegan is to be built by Morris, Ganse & Company.

Springfield, Ill.—Senator Thiebe's bill allowing cities and villages to maintain electric plants and furnish light, heat and power has passed the Senate.

Homestead, Pa.—In the 33-inch mill of the Carnegie Company here, the tables and other machinery are now moved by electricity, recently introduced.

Richmond, Va.—There is now a trolley line to Seven Pines, the scene of one of the great battles of the war and only a short distance from the National Cemetery.

Orange, N. J.—The council has granted the Cross-Town and Bloomfield Railway Company permission to change its motive power to the overhead trolley system.

Bowie, Tex.—A company has been organized to erect and operate a telephone line between Bowie and Jacksboro. It will also probably have a branch line to Post Oak.

Cleveland, Ohio.—The consolidation of four out of the five electric street railway companies of this city is now all but complete, and a large increase in capitalization is to follow.

Scranton, Pa.—The plant of the Wightman Electric Manufacturing Company, against which executions were issued amounting to $74,066.66, will be sold by the sheriff on the 27th inst.

Kingston, Can.—The Kingston Street Railway Company has applied to the Ontario Legislature for permission to change the motive power of its road to electricity and to extend its lines.

Boston, Mass.—The trustees of Thomson-Houston securities, series D, have declared a semi annual dividend of 25 cents per share, payable May 1, 1893, to shareholders of record April 22, 1893.

McKeesport, Pa.—The electric light company, recently burned out, are re-establishing their business as fast as possible. The company intend to introduce the Westinghouse alternating current system.

St. Louis, Mo.—John Scullin, the manager of several street railways in St. Louis, has become interested in the storage-battery system of the Standard Electrical Company of Detroit, and will give it a trial on one of the roads here with a view to its adoption if it proves a success.

Wilmington, Del.—The Wilmington and New Castle Electric Railway Company have elected these officers: President, Dr. Howard Ogle; vice-president, James B. Toman; secretary and treasurer, Harry H. Billany. This organization will stand until the stockholders' meeting July 1st.

Canandaigua, N. Y.—The Canandaigua Electric Railway Company having obtained the franchise of the Canandaigua Street Railway Company, will begin at once to make such changes as they deem necessary in the line and its equipment. They will get motive power from the local electric light plant.

Montreal, Can.—The council of the municipality of Pointe aux Trembles has granted a thirty years' franchise to the Corriveau-Williams syndicate to operate an electric railway and electric light system in the municipality. It is a suburb of Montreal and considered the prettiest location on the island.

Northampton, Mass.—A large interest in the Northampton Street Railway has been sold to three Springfield men. John Olmstead, A. E. Smith and N. D. Winter, and the directory has been reorganized so as to take them in, some of the old members resigning. The work of equipping the road with electricity will begin immediately.

Gallatin, Tenn.—The purchase of the Gallatin and Nashville turnpike by a syndicate of capitalists, who intend to use it for a proposed electric railway, has been made public. The length of the road is twenty-six miles. Among the stockholders of the purchasing company are Horatio Berry, George Seawright and Robert Groves, of Hendersonville.

Fort Wayne, Ind.—Almost every new house being built here this spring is wired for electrical illumination. The Jenny Electric Light Company, which has now 7,000 incandescent lamps burning in the city, intends putting in new machinery and otherwise improving its plant. The company expects to have 10,000 incandescent lamps burning next fall.

Hagerstown, Md.—The street commissioners have awarded the contract for lighting the streets for five years to Rodgers, Shanley & Company, of New York, with the condition that the contractors construct the street railway and operate it in connection with the lighting. The Schuyler Electric Company, who own the present electric light plant, and whose bid was lower, will contest the action of the commissioners.

Brooklyn, N. Y.—The Brooklyn, Bath and West End Railroad has filed with the State Railroad Commission an application for a change of motive power from steam to electricity on the present line of the steam railroad, and also on the spur or branch from New Utrecht to connect with the tracks of the South Brooklyn Railroad and Terminal Company.

Yonkers, N. Y.—The new building of the Otis Electric Company is completed, and the machinery is being put in preparatory to commencing work. It is expected that everything will be in readiness before June 1. The new building will be devoted to the manufacture of electric motors.—The Yonkers Electric Railroad Company has completed its Mt. Vernon line.

Eden, Pa.—At the annual meeting of the Langhorne Electric Light and Power Company, held here, the following directors were elected: Allen R. Mitchell, Thomas Duffield, J. Howard Marshall, P. M. Minster, Edward Townsend, John Rue, David J. Matlack. All were members of the old board, except Edward Townsend, who was elected in place of George L. Garsed.

Newark, N. J.—The Suburban Traction Company, the newly formed organization which proposes to construct and operate an extensive system of cable and electric railroads in Essex and Passaic Counties, has elected the following board of directors: Frank W. Child, A. P. Foster, John L. Seward, George Spottiswoode, T. W. Foster, James Eustis, and W. P. Pritchard. F. W. Child has been chosen as president, A. P. Foster as treasurer, and A. W. Kissam as secretary of the company.

Toronto, Can.—The Canadian General Electric Company, which recently received the town franchise for an electric street railway, has amalgamated with the Peterboro and Ashburnham Railway Company, under the charter of the latter, for the purpose of constructing and operating the road. The officers elected were: T. E. Bradburn, president; Frederic Nicholls, vice-president; directors, H. P. Dwight, T. G. Hazlitt, A. Stevenson, E. H. D. Hall, Wm. Walsh and A. P. Poussette.

Hartford, Conn. — The Hartford Electric Light Company has been authorized by the Legislature to increase its stock to $500,000.—The "Electric bill" now before the Legislature is creating dissatisfaction among the people, as it is likely, if it passes, to put a stop to electric railway building in the State. Strong objection is made against the sections giving the railroad commissioners power over the corporations, and especially against the sections prohibiting the carriage of freight and the substantial paralleling of steam roads.

Cincinnati, O.—George B. Keefer, a Cincinnati capitalist, has organized the Put-in-Bay and Southwestern Electric Railway Company for the construction of an electric railway from Findlay, through Fostoria to the lake. The objective point of the line is understood to be Toledo, and it will be equipped for both freight and passengers.—The Mt. Adams electric is to be extended to Oakley, and the belt road round from Eastern avenue to Mt. Lookout, to Hyde Park, and down town, is said to be assured.

Grand Rapids, Mich.—The West Michigan Electric Company has commenced work on the dams for the water power at Lowell, which is to be used for transmitting electric power, and which power it is proposed to retail in this city for light manufacturing and other purposes. The dams are to furnish 3,000 horse power, which will be generated through the medium of horizontal water wheels. E. F. Sweet, A. C. Sekell and John E. More are local stockholders. The others are C. J. Church of Greenville and C. A. Church and Dr. McDaniel of Lowell.

Boston Notes.

The consolidation of New England electric street railways continues to take place. This time the Haverhill & Groveland Street Railway, the Merrimac Valley Company of Lawrence, and the Lowell, Lawrence and Haverhill Company have become one. Each company will retain its own name but all will henceforth be under one management. Extensions on a large scale will now be made, and extensive car and repair shops will be erected in Haverhill immediately.

The Taunton Street Railway Company has secured authority for double tracking its system and will go ahead at once.

North Attleboro, Mass., after deferring the matter until the experiment had been successfully made by some other town, now seems as if it would like to adopt the Municipal Lighting Act, 1891, and erect a municipal lighting plant. A sum of $50,000 has been appropriated for that purpose.

Next to the plain, ungarnished statements of facts about the first annual report of the General Electric Company which appeared in the last issue of ELECTRICITY, the full and searching analysis of the same document which was published in last Saturday's *Commercial Bulletin* has created most interest in Boston electrical and money circles. That the bankers, speculators and business men of the country generally regard with interest these articles and believe their statements is proven by the turn General Electric stocks have taken downwards, until at present writing common stock is below par.

The bridge which crosses the mouth of what is called Weymouth Fore river at Quincy Point is being widened to make room for the electric car track that is to be laid across it, thereby connecting the Quincy and Weymouth electric railway systems.

Probably the handsomest if not the largest switchboard ever made in New England was shipped from the works of the W. S. Hill Electric Company, Boston, last week, to the Narragansett Electric Light Station, Providence, R. I. It was of white Italian marble with massive brass fittings.

Though enjoined against making any of its popular and efficient lamps, the Beacon Vacuum Pump and Electrical Company of this city is not by any means allowing itself to be idle, and its past enterprise and success are bearing fruit even now. The Beacon system of exhausting lamp bulbs has attracted universal attention, and its foreign patents are being eagerly sought after by capitalists and others. Among the most recent visitors to the Beacon factory were Herr Alexander Von Babo and Dr. Siemens, representing the Siemens-Halske Electric Company. This rich corporation is negotiating with a view to purchasing some of the European patents on the Beacon Vacuum Pump. Incidentally it may be stated in this connection that some time ago ten Beacon lamps were placed in service at a certain place in Canada and burnt for no less than 5,420 hours each before they had to be replaced by new lamps.

The New Sunbeam Lamp.

The new Sunbeam Incandescent Lamp, which has several times received mention in ELECTRICITY, and has been for some weeks looked forward to, is now ready for the market, as is announced in the advertisement of the Ansonia Electric Company of Chicago (formerly the Electrical Supply Company), who will have the Western agency for this lamp. Already large numbers of orders are being received by the Ansonia Electric Company, and every mail brings letters from their old lamp customers, expressing satisfaction at the prospect of their being able to obtain lamps that can be used with some satisfaction and not be compelled to burn lamps that are every day proving more unsatisfactory to their customers.

We have had an opportunity to examine some of the new Sunbeam lamps, and they give every evidence of not only being equal in quality to the old lamps, but fully substantiate the claims of superiority which are made for them. There seems to be no doubt whatever but that this lamp is clearly around the Edison patents. It is not all glass, does not contain inleading wires nor does it have a vacuum. Even the shape of the globe has been changed. The appearance of this lamp just at this time will prove to the General Electric Company a serious obstacle to the realization of its purpose to obtain control of the electric lighting industry. We have learned of several other new lamps that may shortly be expected to appear on the market, and altogether it seems not improbable that the immense amount of experimental work which in the incandescent lamp field has been recently carried on will result, as it has in this case, in the production of a superior lamp, and will confer a lasting benefit on the industry.

The United Electric Improvement Company.

The above is the official title by which the Heisler Electric Company of Philadelphia will hereafter be known to the public.

The United Electric Improvement Company is a protege of the United Gas Improvement Company, a corporation whose financial strength and progressive methods are well known.

The new corporation will immodiately commence the erection of new and commodious factory buildings convenient to the Pennsylvania and Philadelphia and Reading Railroads at Germantown Junction. The factory will be equipped with additional tools and all modern accessories for the manufacture of all kinds of electrical equipment and will continue the manufacture of the Improved Heisler System of Long Distance Series Apparatus. It is also their settled policy to vigorously push after their share of the general electrical business, and with the proposed increase in facilities they expect to render a good account of themselves in the field of competition.

The former officials of the Heisler Company retain their positions in the new company, Mr. Walter F. Smith being general manager and Benj. F. Tingley secretary.

The United Electric Improvement Company will, we are confident, prove a formidable competitor to the Trust in Philadelphia.

The Logan Storage Battery.

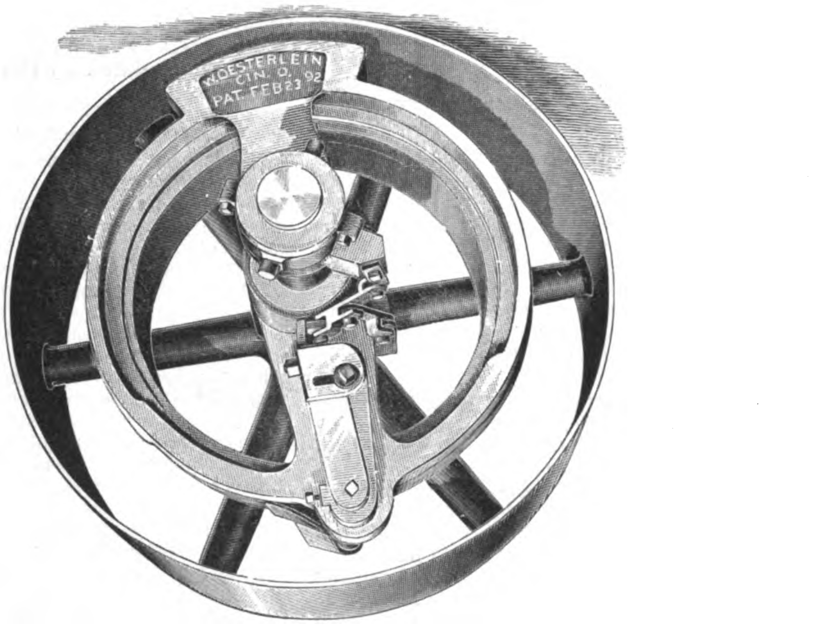
Mr J. W. Johnson, representing the Standard Electrical Company of Detroit, owning the Logan storage battery patents, has recently been in St. Louis, and reports the closing of three important contracts for the use of the Logan battery for lighting and motive power purposes. One of these contracts is for the equipment of three cars on one of the St. Louis street-railway lines.

Mr. Johnson is an enthusiast on the subject of the Logan battery and says:

> "We have solved the problem of a perfect storage battery. I will guarantee to construct a battery which shall not weigh more than a locomotive with its tender and supply of water and coal, which will pull a train of cars from St. Louis to Chicago in one-third less time than does a steam locomotive, and on one-third less cost of fuel for generating the electricity. And at the same time we dispense with all cinders and smoke and with the hissing of steam and puffing of the exhaust."

A Friction Clutch Pulley.

The accompanying cut shows a device that is being manufactured by W. Oesterlein, engineer, Cincinnati, O. and meeting with a very ready demand wherever such apparatus is used. In designing this device the inventor aimed at producing a clutch that should have the largest possible friction surface, clutching the pulley with equal pressure all around, controlled by one lever, and easily adjusted with one screw. The clutch ring, which, as will be seen, is carried on the arms of the pulley, is surrounded by a band whose friction face is composed of hard wood blocks. The ends of the band are pivoted to short arms on the end of a bolt, so that a slight turn of the latter on its axis, draws the ends of the band toward each other, causing it to grip the ring, a slight turn the other way loosening it. This bolt passes through a lug at the top of the ring, as shown in the cut, and to its outer end is secured by a set screw a lever which projects towards the centre of the pulley. Mounted on the lever is an adjuster provided with a cross slot, so that it may be moved across the face of the lever and held in any desired position by a set screw. The lower end of the adjuster is connected by a toggle-joint to the sliding collar on the shaft. As shown in the cut, the collar is drawn away from the hub so that the motion of the toggle shifting the lever to the left releases the clutch. When the collar is moved toward the hub, the long link of the toggle takes a position at right angles to the axis of the shaft, forcing the lever to the right, and causing the friction band to grip the clutch with a force determined by the position of the adjuster on the face of the lever. By loosening the set screw in the adjuster, a slight shifting of the latter will take up or compensate for any wear on the clutch. It will readily be appreciated that the principles adopted in its construction render this clutch one of the most efficient on the market, and it is not surprising that it is being so generally used in electric light and power stations throughout the country.



A Friction Clutch Pulley.

The Interior Conduit System Goes.

The best evidence that the Interior Conduit and Insulation Company's claims for their system rest on a solid foundation is found in the fact that out of all the buildings under construction in New York City since January 1st for which the architects' specifications name electrical equipment, two only are using other than the Interior Conduit system. The metal covered conduit is now generally insisted upon by architects for the best construction. It is estimated that in the remodeled residence of Cornelius Vanderbilt, at Fifty-seventh street and Fifth avenue, 100,000 feet of brass-covered Interior Conduit will be used by the Tucker Electrical Construction Company which has the work on hand.

The Cutter Push Button Switches.

Mr. Charles D. Shain, 136 Liberty street, New York, sends out the following notice in regard to the latest addition to his line of good things:

"The selling department of the Cutter Electrical Manufacturing Company, Philadelphia, in this vicinity, has been placed in our hands.

"It affords us pleasure to present to your consideration the Cutter Push Button Switches.

"We have all read many newspaper articles about 'touching the button and the light appeared,' but there has never been until now a practical Push Button Switch—in fact all switches have had some other kind of movement, and have been more or less unsightly and disappointing.

"The Cutter Push Switch is unique in design, beautiful in finish, electrically and mechanically perfect. There is nothing in sight but an ornamental face plate, set flush with the surface of the wall.

"The prices are quite reasonable, and it will afford us pleasure to quote you upon receipt of information as to your wants. We have a neat catalogue and price list, which we will send on application. Specifications of architects, engineers and others should call for these switches."

Will Keep Open House.

The Railway Equipment Company of Chicago, Mr. W. R. Mason general manager, sends out the following invitation to World's Fair tourists:

> Assuming that it is your intention to visit the World's Columbian Exposition, and realizing that you will be pleased while here to meet others interested in the operation of street railways, we have thought it might be a convenience for us to open a directory of visitors to the Fair.
>
> As it will probably be also a convenience for you to meet your friends at a central and accessible point, we would be pleased to have you send to us the names of those of your company who expect to be in Chicago at that time, giving also the date of arrival and, if possible, the hotel or apartments where you may be found. As soon after arrival as convenient, we would suggest that you call and register at our office, which is in perhaps the most convenient and prominent location in the city.
>
> Our office is directly opposite the new Art Gallery, where the World's Fair Congress will be held, and is almost directly opposite the main depot for World's Fair trains. We shall certainly take pleasure in extending every courtesy to our friends during the six months, and we trust you will make our office your headquarters, and, if desired, have your mail addressed in our care. In the meantime we shall be pleased to furnish any information needed, as well as to attend to any matters connected with your visit to the Fair.

INCORPORATIONS.

The South Waukegan Electric Railway Company, Shields, Lake County, Ill. Capital stock, $100,000. Incorporators: Franklin W. Ganse, Calvin Dicky and Bryan Y. Craig.

The Indiana Natural and Illuminating Gas Company, of Indianapolis. Capital stock, $1,000,000. Incorporators: C. F. Diederich, E. J. Jerzmanowski, J. H. Benedict, A. W. Brady, Samuel Thorne, A. B. Proal and John R. Pearson. The objects of the company are to prospect and bore for natural gas and to produce artificial gas and electricity for light, heat and power.

A certificate of incorporation has been granted the company which intends to construct the Ellicott City and Clarkville branch of the proposed electric railway from Baltimore to Ellicott City. The capital stock is $200,000. Incorporators: State Senator John G. Rogers, Harper Carroll, John F. McMullen, John L. Clark and John H. Owings. The directors named are the first four of the incorporators and Messrs. Frederick Bausman, of Glenelg, Howard County; George Yakel, Van Courtlandt Homans, N. Winslow Williams and Henry W. Williams, of Baltimore, Md.

Mount Vernon Electric Light Company, of Mount Vernon, Ill. Capital stock, $20,000. Incorporators: Allen C. Tanner, George W. Evans and Wayland S. Arnold.

The Abatis Electric Manufacturing Company, at Chicago. Capital stock, $50,000. Incorporators: A. R. Hussey, Nelson Erickson and William Newman. Organized for the manufacture of electrical appliances.

The General Electric and Improvement Company, at Trenton, N. J. Capital stock, $500,000. The company will begin business with $3,000, divided into thirty shares as follows: Louis A. Chandler, 28; Charles N. King, 1; Wm. J. Turner, 1. It is supposed that the company is organized for the purpose of acquiring an interest in certain telephone and electric-light companies.

The Delaware and Schuylkill Railway Company of Philadelphia. Incorporators: Harry C. Forest, Robert A. Welsh, Robert Libberton, A. H. Harley, William L. Martin, William Hill. The company is to build and operate trolley railway lines in certain specified streets in Philadelphia and Germantown.

The Montana Electric Company, Butte, Mont. Capital stock, $50,000. Incorporators: John O'Rourke, G. T. Schmelzel, S. B. Smith, W. F. Jackson, V. E. Poissant and C. L. Smith. The company proposes to do a general electric business in the State with headquarters at Butte.

The Put-in-Bay and Southwestern Electric Railroad Company, at Columbus, Ohio. Capital stock, $3,000,000. Incorporators: George B. Kerper, J. K. Tillotson, J. B. Foraker, August Fabel and C. A. Gordon, all of Cincinnati, with the exception of Mr Tillotson. The object of the company is alleged to be to build an electric railway from Findlay through Fostoria, and eventually to Toledo.

The Beecher Single Rail Company of Buffalo, N. Y. Capital, $400,000. Directors: Charles A. Seaver and Lina Beecher of Batavia, Guy C. Hardesty and Alfred J. Hibbard of Buffalo, and George W. Sikes of Lakeview. The company's purpose is to manufacture all kinds of electric motive power, locomotives, railroad and street cars, gas and compressed air motors.

The Salmon City Electric Light and Water Company, Salmon City, Idaho. Capital stock, $40,000. Directors: E. C. Johnson, president; William F. Boxwell, Jr., secretary and treasurer; Ed. Mingle, vice-president; John R. Stout and John J. Egan. The object of the company is to furnish Salmon City with water and light.

ELECTRICAL PATENT RECORD.

Letters Patent Issued April 18, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

495,615. Cross-Over Switch for Electric Railways. Frank B. Rae, Detroit, Mich., assignor to the Detroit Electrical Works, same place. Filed April 11, 1891.

495,674. Rail-Circuit-Closing Contact. Friedrich von Hefner-Alteneck, Berlin, Germany, assignor to Siemens & Halske, same place. Filed Jan. 18, 1893.

495,692. Trolley-Wire Finder. Charles G. Cleminshaw and William H. Bradt, Troy, N. Y. Filed June 22, 1892.

495,695. Electric-Railway Trolley. William Duncan, Allegheny, Pa. Filed July 20, 1891.

495,940. Electric Trolley. Jeannot W. Kenevel, Chicago, Ill. Filed March 26, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

495,601. Electric-Arc Lamp. Frederick T. Schmidt, Bradford, England. Filed Aug. 24, 1892

495,620. Incandescent Electric Lamp. Eugene W. Applegate, Chicago, Ill., assignor to the Applegate Electric Light and Power Company, same place. Filed Jan. 8, 1893.

495,648. Electric-Arc Lamp. William A. Turbayne, Detroit, Mich., assignor, by mesne assignments, to the Turbayne-Tamblyn Company, same place. Filed July 1, 1892.

495,676. Electric Lamp. Tobias Hudson, Baltimore, Md., assignor of one-half to John F. Weyler and Robert S. Weisenfield, same place. Filed Oct. 7, 1892.

495,772. Electric-Arc Lamp. Ernest E. Beauvalet and Leon C. Beauvalet, Paris, France. Filed July 11, 1892.

495,932. Electric-Lighting System. Henry Edmunds, Jr., London, England, assignor of nine-tenths to Albert Sechrist, Denver, Colo. Filed Oct 19, 1892.

495,951. Incandescent Electric-Lamp Holder. Leroy C. Whitney, Jr., Milwaukee, Wis. Filed Dec. 10, 1892.

DYNAMOS AND MOTORS.

495,538. Dynamo-Electric Machine. Thomas L. Willson, Brooklyn, N. Y. Filed March 8, 1890.

495,547. Combined Electric Motor and Driven Machine. Rodolphus Fuller, Detroit, Mich. Filed March 31, 1892.

495,561. Commutator for Dynamo-Electric Machines or Motors. Buchanan S. Paterson, Gateshead, England, assignor to Clarke, Chapman & Company same place. Filed Aug. 16, 1892.

495,562. Field-Magnet. Frank A. Perret, Springfield, Mass., assignor to the Elektron Manufacturing Company of New York. Filed Oct. 28, 1892.

495,941. Electric Motor or Generator. William Koedding, St. Louis, Mo., assignor of one-half to Edmund Verstraete, same place. Filed Sept. 21, 1891.

BATTERIES.

495,638. Secondary Battery. Leslie B. Rowley, Ashland, Wis. Filed Sept. 23, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

495,744. Method of Indicating Telegraphic Messages. Joseph Levi, New York, N. Y. Filed Jan. 16, 1893.

MISCELLANEOUS.

495,552. Insulator. Louis Hills, New York, N. Y. Filed Aug. 22, 1892.

495,564. Electrical Bell. Henry B. Porter, New York, N. Y. Filed Oct. 26, 1891.

495,582. Ground Generator of Electricity. Michael Emme, Oakland, Cal. Filed Aug. 29, 1892.

495,587. Ship's Log. Charles F. Holt, New London, Conn., assignor of one-half to William S. Starr, same place. Filed July 25, 1892.

495,600. Electrolytic Apparatus. Gustaf O. Rennerfelt, Stockholm, Sweden. Filed Sept. 30, 1890.

495,608. Magnetic Ore-Separator. George G. Crosby, New York, N. Y., assignor, by direct and mesne assignments, to the Magnetic Ore Milling Company of West Virginia. Filed Jan 27, 1892.

495,626. Electric Welder for Wire-Fence Machines. John D. Curtis, Worcester, Mass. Filed Nov. 2, 1892.

495,637. Process of Extracting Zinc by Electrolysis. Johannes Pfleger, Frankfort-on-the-Main, Germany. Filed Aug. 23, 1892.

495,714. Lightning-Arrester. Elihu Thomson, Lynn, Mass, assignor to the Thomson-Houston Electric Company of Connecticut. Filed Aug. 5, 1889.

495,738. Electric Rotary Drilling-Machine. Robert M. Jones, Salt Lake City, Utah. Filed June 30, 1892.

495,782. Electric Shoe-Sole. Rufus F. Carnes, Winfield, Ala. Filed Dec. 22, 1892.

495,853. Lightning-Arrester. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Feb. 15, 1892.

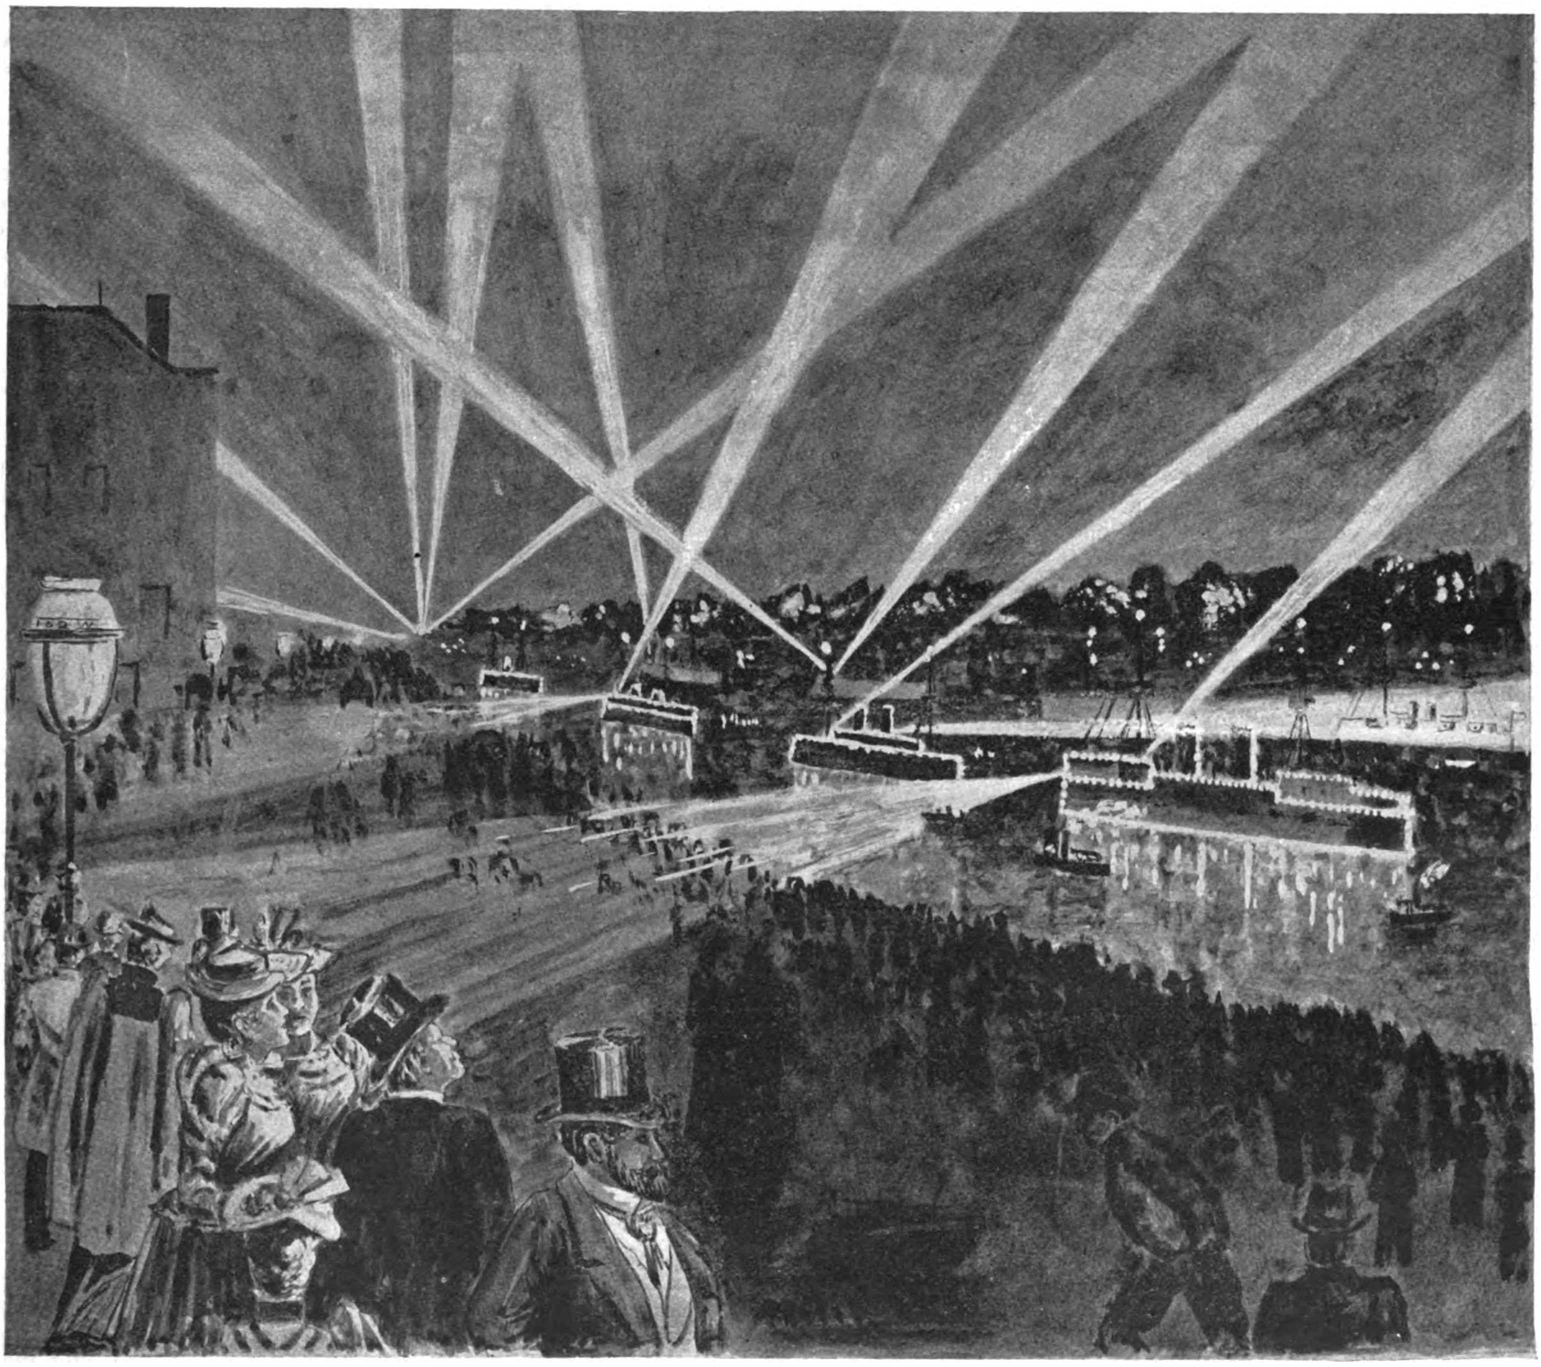
495,861. Electric Belt. George F. Webb, Cleveland Ohio. Filed Dec. 16, 1892.

495,913. Danger-Signal for Railway-Crossings. James S. Savage, Jr., Detroit, Mich., assignor of twenty-seven one-hundredths to George Farnsworth, same place. Filed June 4, 1891. Renewed March 27, 1893.

495,929. Electric Cigar-Lighter. William Carter and Charles E. Willey, Louisville, Ky. Filed July 18, 1892.

ELECTRICITY.

Vol. IV. New York. MAY 3, 1893. Chicago. No. 16



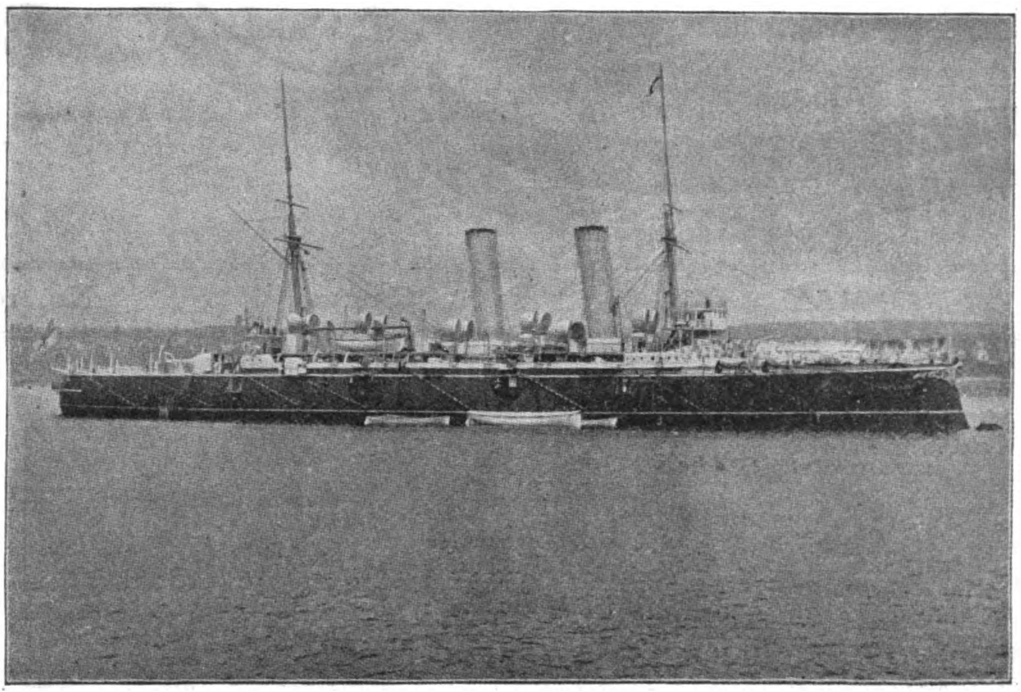
EXHIBITION OF SEARCH-LIGHTS, NORTH RIVER, NEW YORK. (See Page 210.)

Electricity in the Naval Review.

Some Equipments on Board the Men-of-War.

The Night Display in the Hudson River.

Everywhere Columbus! It is the sole topic. The air is redolent with the name. The news-stands are piled with a mass of literature and cheap prints of "Caravels," "Voyages" and "Landings." The newspapers, the magazines and the weeklies devote column after column to historical research dating and antedating 1492. The navies of the civilized world are concentrated at one station to do honor to the name, and even the postage stamps have been altered to accord with the spirit of the hour.



British Cruiser Blake.

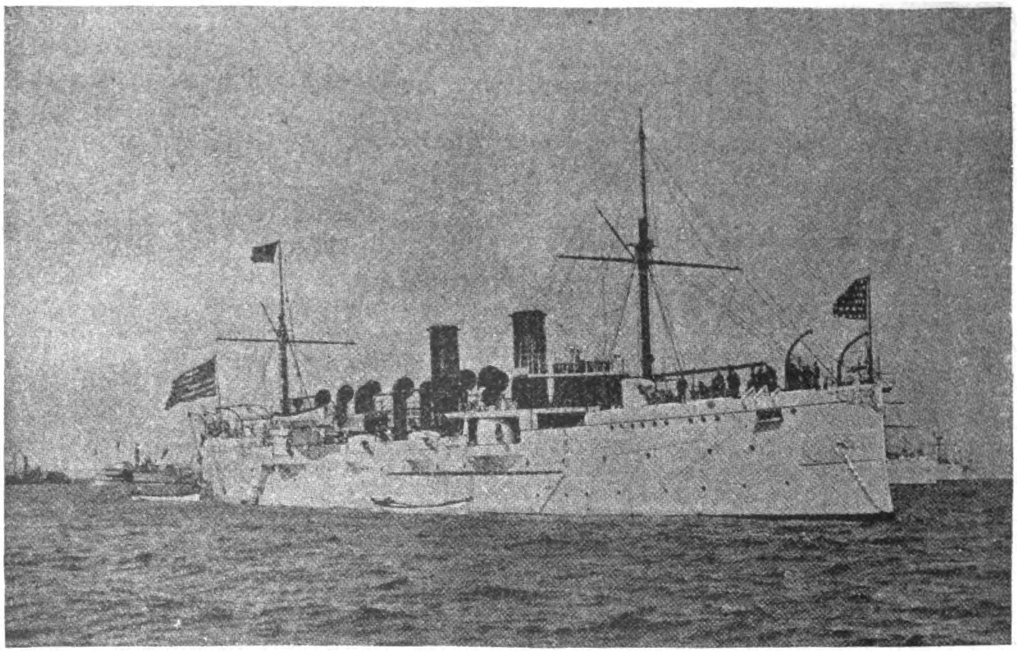
The point of view, at this late day, is concerned more with what the achievement has developed into rather than with the achievement itself. It is to be doubted whether the slightest fraction of the multitude that will visit the just opening Exhibition will devote more than a passing thought to the intrepid navigator of which it is in honor. The past is relegated to the limbo of forgotten achievement and only to be resurrected on special occasions like the present, when all is Columbus and caravel and anticipation.

Nothing more forcibly exemplifies this proposition than the demonstration which has taken place during the past week in and around New York City and its harbor. Thirty-five ships of the great navies of the world constitute as inspiring a pageant as we may hope to see in our generation. Only once has it been approached in an attempt to outdo former spectacles, and that on the occasion of the Queen's Jubilee at Spithead, Eng., some few years ago. In the present instance no expense or energy has been spared to make the affair a success, and strange as it may seem it has not turned out a fizzle as is generally the case.

The assemblage at Hampton Roads was accomplished by this complex squadron of evolution without more than a minimum of set-back. Great Britain, Russia, France, Italy, Germany, Spain, Brazil, Holland, Argentina and the United States each was represented by its most typical exemplification of modern naval construction. Dipped in the waters of that other early navigator, Hendrick Hudson's, "Great North River," they stretch in two formidable lines for the length of forty-eight city blocks.

At the top of the line the fantastic looking caravels rock and rear their eccentric hulks to the motion of the tide and illustrate forcibly the enormous advance which has been made in nautical architecture during the last four hundred years.

This is the keynote on which the intelligent observer will most dwell as he contemplates and compares the formidable appearance of the modern vessel with the almost "junk" of other days. After the first inspection of the old tub itself his eye lights on a piece of "heavy" ordnance which it is said is one used by Columbus on his first memorable voyage. The approved method of securing the cylinder to its carriage by means of hemp is noticeable. The guns of the present time are capable of covering distances, producing results, and in such an infinitesimally small period of time as to lead us to think that perfection must surely be reached. Yet this old gun in its time was considered a masterpiece.



United States Cruiser Philadelphia.

Heading the two lines are the Philadelphia (U. S.) and the Blake (British). As modern battle-ships go they are good examples of what is latest in all that pertains to improvement in men-of-war.

The most interesting portion of a ship's equipment is of course its guns. The modern gun is a most intricate piece of mechanism and naturally involves a considerable amount of manipulation. The guns of a ship's battery are divided into groups called gun divisions. A subaltern, usually an ensign or junior lieutenant, is always placed in charge of each gun. Depending on the ship's equipment its guns may be fired by individual electrical circuits attached to the gun, or they may be controlled entirely from the "conning" tower.

The latter method is employed on several of the present vessels but is rapidly falling into disuse. The conning tower is on the fore part of the upper deck and is a protected observatory from which every motion of the vessel or action on board of her may be controlled.

THE CONNING TOWER OF A MAN-OF-WAR.

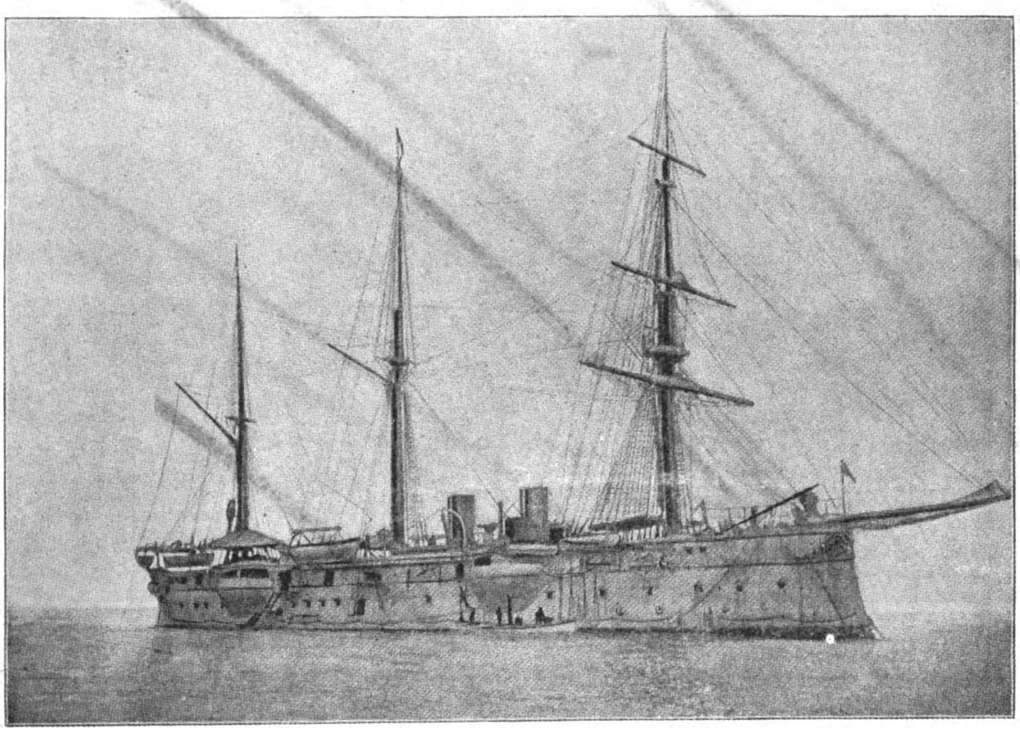
In the conning tower the commander of the vessel can with a mere touch of the button bring within his control any desired order of movement on the part of officers, men, or apparatus on board. It is, therefore, the central station from which everything is directed. Electric circuits abound everywhere—in fact, they do so all over the vessel, but here in particular do they loom up in vast array. On board the Blake the steering apparatus is guaranteed an absolute amount of accuracy by the apparatus known as the helm telegraph. As it is peculiar to the Blake alone it will bear description. The instrument consists of a dial with division in degrees marked on the face of it. A handle controlling a bar at the back has also a pointer which indicates the number of degrees. A similar instrument is situated aft in the steering department, and the construction of each is such that the working of one reproduces a similar effect on the other. The helm itself, also by another telegraph of a similar nature, records its exact movement in the conning tower. The commander may thus have absolute and instant command of the vessel's movements and yet be in a position to take note of the enemy's movements. Elliott Bros., London, are the makers and installed the apparatus.

Although every provision is made aboard the Blake for the explosion of the ordnance at a given signal from the conning tower, they do not believe in causing a universal explosion by a circuit from that point. The reason is manifest and logical. It is patent that the individual gunner is in the best position to determine the sight, range, and precise moment a shot is to be delivered. The exigencies of battle, smoke, mist, and other details, make it extremely difficult to determine the effectiveness of a broadside regulated from a position where the difficulties cannot be so apparent.

The guns on the Blake are now fired from individual circuits worked by the officer in charge of the gun station.

From the conning station it is possible to control the helm, the guns, the search-lights, torpedoes, etc., as well as the engine rooms, cabins, etc., thus instituting a perfect system of intercommunication which is as efficient as it is intricate. The compass box (Lord Kelvin's standard) is lighted by the current—16 C. P.

On board the Blake are three Siemens compound wound dynamos, 80 volts each and 450 amperes, any one of which is capable of carrying the total ship's load irrespective of the search-lights. Two of these dynamos are far down below the surface of the water, and so entirely out of harm's way. The other is in a compartment protected but yet not impregnable to an enemy's shot. If, however, it should occur that any one dynamo should be damaged in action, the load can very easily be carried by either of the other two. The dynamos are direct coupled and Brotherhood engines are used. Siemens ammeters and Carden voltmeters are used. These dynamos furnish current for the 100 C. P. incandescent lamps which are used in signaling, also for 100 50 C. P. incandescent lamps used for lighting the coal bunkers. The internal lighting arrangement of the ship is very efficiently disposed. Six hundred 16 C. P. lamps are distributed in the most desirable spots on board. Each illuminating lamp is protected from injury by a semi-sphere of thick glass which has its own protection of wire netting. Every available space when it could not be used for anything else seems to contain some kind of electrical equipment. The yard and arm group for lighting the coal bunkers is run by the upper dynamo. That is the one on the main deck. It stands in an enclosure of its own surrounded by six-inch walls of steel, which are enough to turn aside the effects of any ordinary explosion which may happen in its vicinity during action.



SPANISH CRUISER NAVARRA.

This isolation of the departments is the prevailing arrangement of the Blake's equipment. Each large gun, controlled by an elaborate system of tubing and wiring from the conning tower, is capable of being thoroughly isolated within its own inclosure of six-inch steel wall. This wall serves the double purpose of protecting from within and without. A shell entering through a port-hole might explode and kill every one in the compartment but the effect would be localized and end in that room, whereas in the old days of open or communicating compartments, or where there was no compartment at all, a single shell might wreck a whole deck.

Directly in front of the conning tower stands the large 9.2 gun with its elaborate settings and fittings. This gun is operated by a local circuit, the safety devices on which are numerous, as indeed they have to be. They consist in making absolute breaks in the circuit by uncoupling in two or more places the twin cable which passes from the internal mechanism of the gun to the hand of the gun captain. In manipulating the machinery of the piece all the connections must be uncoupled in order to allow any freedom of movement. In sighting and aiming the gun the ordinary large gun-sights are used during the daylight, but at night their places are taken by tiny incandescent lamps which stand out of the gloom with a distinctness that admits of no misunderstanding their position or object.

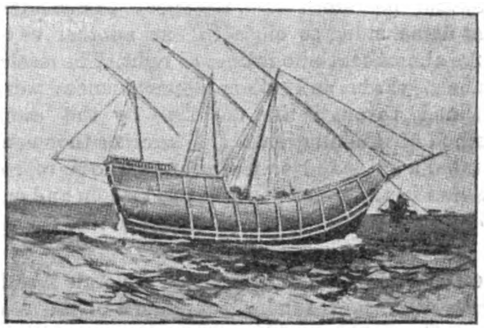
Down some fifteen feet or so below the water-line the torpedoes lie. The action of the shell is of course due to compressed air, but this is released by the electric current. The action is simple. A press button operates an electro-magnet which releases a heavy ball weight which in its turn relieves the mechanism of the torpedo itself.

Part of the equipment of the ship, and a most important feature, are its five search lights; 25,000 candle power is the estimated concentration of each beacon. Search-lights, except in power, differ very little on different men-of-war. There is the ordinary arc arrangement with a condensing lens and reflector, and a small blind to prevent any "direct" rays from escaping.

Every lamp used on board the British fleet, for the Blake is typical of the equipment of the rest, with a few improvements added, is of the Swan pattern, and every lamp has its protecting switch and cut-out. All wires are lead covered, and each individual lead is painted a different color, for the purpose of selection and repair.

All the fine instruments on board were made by Elliott Bros., of London, and they include a Wheatstone bridge with a 1,000 ohm galvanometer, a Thompson reflecting galvanometer for sensitive work, balancing cables, etc., etc.

The Blake is typical of what to expect on the modern man-of-war. The types of the different nations differ very little materially from each other. The latest improvement, except in cases where exclusive control or where secrecy is maintained, is pretty sure to be adopted and installed by the contractors when in their power, or by the Government when it assumes control. On the Philadelphia, the pride of the United States Navy at present, we find installed the Edison system, with only the difference which the different fittings produce. Further down stream the Newark illustrates the cosmopolitanism of equipment by her furnishings being found of the same make in many instances as the Blake's.



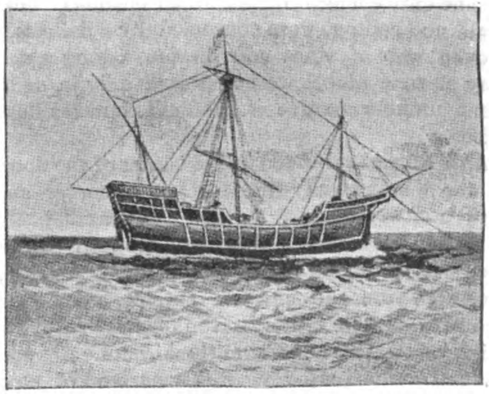
NINA (FAC-SIMILE OF THE COLUMBUS CARAVEL).

One point which obtains on board the United States cruisers, and is worthy of comment, is the Ardois system of signaling. The arrangement consists in having rows of lanterns swung from the mast-head to the deck. The lantern is made to show two colors—red and white—and by alternate flashes and combinations of colored lights the different messages are transmitted. Each lantern is a cylinder of glass one-half of whose length is red and the other half white. An incandescent lamp is placed at each end, and they are worked by a keyboard from below. As each end is illuminated the corresponding color is made to gleam white or red through the darkness.

Such a congregation of modern naval talent will be with us but a few days longer, and it but remains to describe what was one of the most beautiful sights coupled with one of the most brilliant engineering feats it has been our pleasure to witness.

On Thursday last the President passed through the lines of the combined squadron to the saluting of guns and the shrieking and crowing of whistles. The daylight manifestations closed, and it was announced that the various vessels would engage in exhibitions of search-lights and Ardois signaling.

But the waiting crowds that thronged the river banks were treated to a far finer spectacle than they could have possibly anticipated. In all directions the search-lights were found darting their beams, which, mounting in many cases to the low-lying clouds, were broken, and finally lost in the strata and super-strata of vapor. The Ardois system, with its alternating red and white gleams, could be seen flashing along the



PINTA (FAC-SIMILE OF THE COLUMBUS CARAVEL).

American squadron over towards the Jersey shore. The grandest sight of all, however, was the illumination of the British men-of-war.

The Blake, Australia, Magicienne and Tartar were found decked in a perfect framework of flame. The grim black lines of the craft were outlined against the darkness by row on row of incandescent lamps which followed the shape of the vessel and made a flame picture not easily to be forgotten. All along the hulls, both at the rails and the water's edge, the specks of incandescent flame clung so close to one another as to make almost continuous lines of light. The masts, funnels, yards and other appurtenances were outlined through the darkness by the same method of illumination, and altogether they constituted a glare and an iridescence whose reproduction in the water beneath was broken and cut up by the rippling waves till it looked like a mass of liquid fire.

Of course all this was a quite separate installation from the ordinary equipment of the vessels. The cables and lamps which composed the temporary display were imported from England, but their arrival was delayed to such an extent that two hours before the time for the exhibition to begin not a line or a lamp was installed. Although a temporary construction, the work was of the most thorough character, and the result was certainly a credit to the ingenuity and dispatch of its promoters.

Approximately estimated, 4,000 Swan lamps (16 C. P. and 80 V.) were used in the decoration of the four vessels. Twin wire cables were used with nineteen wires in each cable. The lamps were placed at intervals of three feet apart, and the installation was divided into sections of fifty lamps. The length of the cable on each vessel approximated 3,000 yards.

Altogether the display as viewed from the river bank was grand, and was the most imposing sight in the day's events, illustrating as it did how important a part electricity has come to play in modern naval display, and intimating the possibility of still greater accomplishment in the future.

The Columbian Ball.

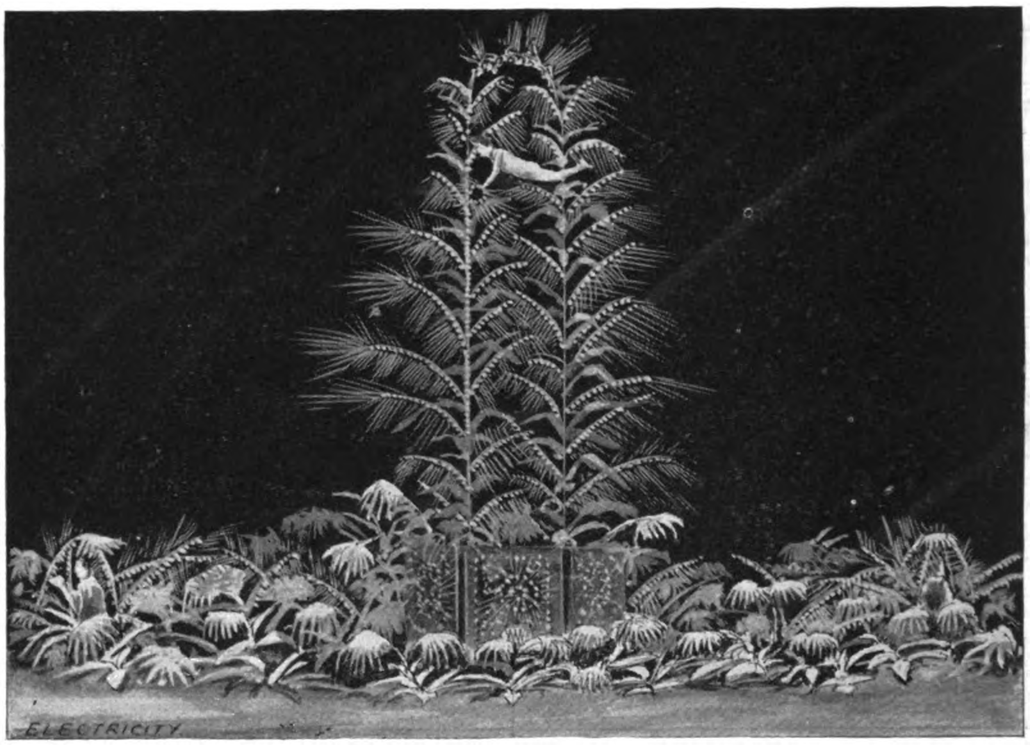
All the World Represented, and the Most Striking Decorative Effects Were Produced by Electricity.

On the night of the 27th, following the display on the river, New York gave a ball at the Madison Square Garden, at which representatives of nearly all nations danced and were happy.

The Garden was transformed by the unstinted use of textures, flowers, plants and electric lights into a fairy land. There was expenditure of money without stint, and the result was so harmonious as to baffle any attempt at description.

The entire length of the broad entrance, both walls and ceiling, were concealed by a delicately woven web of vines and flowers among which tiny electric globes were scattered only in sufficient number to give a subdued but brilliant effect.

A grove was arranged in the center of the floor. It was about twenty-five feet in diameter and made a most attractive feature. It was composed of palms, rose bushes, lilies and tropical plants, each one having an electric light by it. A pretty arch rose from the centre. Its sides were studded with electric lights in the form of sprays of lilies of the valley. From the keystone was suspended a silver cupid bearing a garland of electric lights in its hand. By the arch stood a curious Japanese figure holding a wheel of electric lights which by a peculiar mechanism were constantly twinkling and changing color, giving the appearance from a short distance of a revolving hoop.



ELECTRICAL DECORATIONS AT THE COLUMBIAN BALL.

The Distribution of Power by Alternate-Current Motors.

BY ALBION T. SNELL.*

Multiphase alternate-current working, although demonstrated at the Frankfort Exhibition, has not yet found favor either in England or America; but on the Continent the Drehstrom has been used with success for several important schemes, and larger applications lie in the near future. It has been pointed out, with justice, that multiphase alternate currents offer no real advantage in comparison with single-phase ones for merely the transmission, as distinguished from the distribution, of power. It is, perhaps, for distribution proper, i. e., where a number of motors, varying in size and lying over an extended area, have to be supplied from a common and probably distant source of power, that the multiphase systems find their field of usefulness.

The object of this paper is to discuss the various alternate-current motors now in the market, and, perhaps, to see how far they lend themselves to a system of distribution in which the principal conditions of supply may be stated as follows: 1. The pressure in the transmission mains must be as high as possible. 2. The pressure must be maintained fairly constant at the centre of distribution. 3. The pressure at the motor and lamp terminals must be comparatively low; and 4. The system must admit of lighting all over the area of distribution by the use of proper converters. These points are by no means easy to obtain even singly, and when they must be concurrent the difficulty is much enhanced.

1. SINGLE-PHASE SYNCHRONOUS ALTERNATE-CURRENT MOTORS.

Single-phase synchronous alternate-current motors have been used since the memorable experiments at the North Foreland in 1884, but comparatively little progress has been made in their application to general commercial purposes; and the reason for this probably lies in the fact that the synchronous system is practically limited to a single pair of machines, for the starting of the motor by auxiliary power is not a prohibitive objection with one large machine, although out of the question with a number. On the other hand, the high efficiency of synchronous motors and their perfect regulation of speed with varying loads renders them especially suitable for a variety of purposes; and no efforts have been wanting on the part of scientists and engineers to place a self-starting single-phase motor in the market, but hitherto without success. It will serve no useful end to describe in detail all the various attempts, but the limiting conditions may be best gauged by a consideration of the difficulties involved, and by a few typical examples showing the directions in which solutions have been tried.

The following peculiarities are found in alternate-current working with single-phase synchronous generators and motors: (*a*) The dynamos are always separately excited. (*b*) The motors are usually separately excited in order to save the complication of commutators. (*c*) The motors must be raised approximately to the speed of synchronism before the dynamo circuit can be closed. (*d*) The torque on any motor must not exceed a certain value or the machine will stop. (*e*) The current lags behind the pressure by an angle which is a maximum when the motor is running light; and there may be a relatively large idle current, which, though representing little energy at the motor, causes a serious loss in the supply mains and dynamo armature. (*f*) Motors must be designed not only with reference to the pressure of supply, but also with regard to the frequency of the current, and hence are only suitable for working on particular circuits; and (*g*) Alternate motors, excited by either a direct or by a single-phase alternating current, have dead points in each period of alternation.

The earliest attempt to meet these conditions was by laminating the field magnets of an ordinary direct-current motor and modifying the winding so as to make the self-induction as small as possible. The results were not successful. With shunt windings it is found to be practically impossible to excite the magnets excepting with large currents and few turns of wire, and even then, owing to the difference of phase between the field and armature currents, the torque is insignificant compared with the current used, and the dead points may involve difficulties. The series winding is better, but still useless for commercial requirements; for though by carefully adjusting the windings it is possible to obtain a smaller lag, the weight output is still very small and the dead points remain.

The loss by hysteresis in each case is so great as to be probably prohibitive, even neglecting the other objections. The crux is the frequency. This would, most likely, have to be reduced to something of the order of 20 ∿ per second, and such a current would be useless for lighting, and would largely increase the difficulty from dead points. Indeed, from this aspect the frequency should be high, and the armature heavy enough to act as a flywheel. The author has made a number of experiments in this direction, and finds that the eye can easily detect 30 ∿ per second, and he believes from this cause it would not be expedient to work at less than from 40 to 45 ∿.

---

*Paper read before the Institution of Electrical Engineers, London.

Another method involves the transformer principle, but is really only applicable to small machines. It originated with Mr. Jacobi, when one of the author's assistants, and a few motors were designed by them conjointly. With this type the armature is wound in the usual way, drum or cylinder, and has a collector of the ordinary type. The field cores are laminated and wound with two windings, one of which is coupled to the supply mains, and the other connected across the armature terminals, thus forming a secondary circuit. Such a motor gives a considerable torque, is self-starting, and has probably an efficiency of 60 per cent. in one horse power machines. It has dead points in each alternation undoubtedly, but they are not very apparent. The chief difficulty is that owing to the configuration of the iron of both field and armature, and the air gap, the number of lines of force passing through the two circuits is not the same; and, moreover, there is a considerable lag between the primary pressure and current. And also, which is equally important, the primary and secondary currents are not in phase. With small armatures having few turns per coil the sparking is little, the best results being obtained when the axis of the armature field is at 90 degrees, or thereabouts, to that due to the exciting current. The armatures may advantageously be wound with two circuits, so as to avoid short-circuiting coils beneath the brushes.

2. USE OF CONDENSERS.

The next step in alternate-motor design was the attempt to balance the self-induction of the shunt-wound field magnets by a condenser, placed in series with the windings. If the condenser be correctly chosen for the frequency and the capacity of the circuit, its E. M. F. will theoretically be equal and opposite to the counter E. M. F. of the magnets, and so the exciting current will only have to be driven against the ohmic resistance of the winding, and moreover the pressure and the field current will be in phase. The armature has but small self-induction, and so its current will be also nearly in phase with the field current, and the maximum magnetism in field and armature will occur at approximately the same instant of time. Therefore the energy absorbed by the motor can be very nearly gauged by the product of the number of volts and amperes. In practice, owing to the armature reactions, the condenser will most likely not exactly counteract the counter E. M. F. at all loads. And again, even assuming such machines to be commercially practicable, they would only be suitable for one periodic time. If condensers were applied to series-wound motors, they would be coupled in shunt to the field windings; but the objections above mentioned are equally applicable. A most important point to be noticed in connection with condensers used in this manner is the relatively high pressure which might occur at the field terminals owing to fluctuations in the current. This difficulty can be obviated by arranging the condenser and windings in sections, but such a plan is open to objection on the score of complication. Messrs. Hutin and Leblanc have recently patented several modifications of designs involving condensers.

An interesting modification of the shunt-wound single-phase motor has been designed by Messrs. Stanley and Kelly. It is well recognized that the lag of the armature current does not coincide with that of the field current in an ordinary shunt-wound motor supplied with an alternating current, and hence the torque is not proportional to the armature current, but has a maximum for some particular value which must be determined experimentally for each machine. To meet this difficulty these gentlemen place a condenser in series with the shunt coils; and put short-circuited coils in recesses cut in the pole-pieces. These coils carry currents induced by and therefore proportional to the armature current, but always in such a direction as to tend to decrease the self-induction of the armature coils, and consequently the lag of its current also. The arrangement has the disadvantage of raising the interpolar resistance, and is likely to cause serious distortion in the main field.

It has also been proposed to supply the idle currents prevailing with alternate-current working by suitable condensers placed across the supply mains, preferably at the transformer substations.

3. SPLIT-CURRENT ROTARY-FIELD MOTORS.

Another attempt has been made in the direction of splitting the main current into two separate branches with phase differences of 90 degs., and so producing a bi-phase rotary magnetic field, the armature circuit being closed on itself, or through an external resistance, and carrying a current induced by the revolving field. In principle this machine is similar to a Tesla motor supplied with two separate currents, one of them lagging 90 degs. If a current be divided into two circuits with different coefficients of self-induction, the current in one will lag behind that in the other; and if the one circuit have no self-induction but capacity, and the other have relatively a large self-induction, then the phase difference can be made as near 90 degs. as desired. Such a machine has been designed by Messrs. Hutin and Leblanc, but the author does not know how far it has been successful in practice. The points gained by this arrangement, however, mark a considerable advance in the design of alternate motors for use off ordinary supply mains. The motor is self starting; non-synchronous; if stopped through overloading, will start again as soon as the excess of load is removed; and is self-exciting. But it appears to be still far from perfect; for, owing to the armature reaction on the field, it is difficult to see how the current, in the circuit containing the condenser, can be self-adjusting for varying loads with a fixed pressure of supply; and consequently the output of such a motor will probably be less than that of a Tesla one with two independent currents. The difficulties attending the condenser are precisely the same as those previously referred to with the synchronous type of motor.

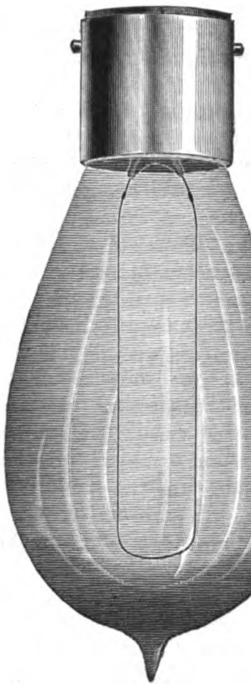
Messrs. Stanley and Kelly have recently devised a quadrature motor which presents some interesting features. In one of the circuits is placed a solenoid with low ohmic resistance but large self-induction; and in the other circuit is a series of secondary batteries which have capacity, and therefore act as a condenser. The result arrived at is a lag of 45 degs. in the current of the inductive circuit, and a corresponding advance in the capacity branch, the result being a total difference of phase of about 90 degs. between the two currents. The battery does not need to have large storage capacity; and as the number of plates is arranged so as just to prevent electrolysis there will be no "forming." But lead plates used in this manner in diluted sulphuric acid rapidly sulphate, and hence are likely to give trouble. Iron plates in caustic soda are also rapidly affected, and even carbon soon crumbles away. Platinum seems to be the only reliable material, and this at its present price is too costly.

(To be continued.)

The "Novak" Lamp.

At last the sitting hen has left her nest and her callow brood are all alive and picking.

The curiosity to know just what the chicks would look like when hatched has been unprecedented, so to allay this curiosity we herewith present a cut of one of the new arrivals, and furnish a brief description of the little bird whose tuneful notes, or, to be more accurate, brilliant rays, are destined to illuminate the footsteps of the troubled ones out of the condition of chaos which the recent litigation, up to a certain date, had evolved.



THE "NOVAK" LAMP.

To enter upon this description then, we may say that the "Novak" lamp may be styled a gas lamp, having no vacuum, and entirely different from any other lamp now on the market. That it is no experiment but a practical lamp of high efficiency is proven by the fact that numbers of them have actually been in constant use since December last. Blackening of the bulb in this new lamp is impossible, while its efficiency and life are equal to any lamp made. One advantageous feature of it is that it will maintain its initial efficiency throughout its entire life, having the same candle power to the very last.

Patents have been granted on this new lamp which the most eminent experts in the country agree in pronouncing free in any single detail from infringing any existing patent.

It is being made now by the Waring Electric Company at its factory, which has a capacity of 5,000 lamps a day. Messrs. Claflin & Kimball, Boston, are general selling agents, and not only is this firm receiving orders by every mail, but heavy shipments are being made from the factory every day.

Electric Rapid Transit.

It is reported that the New York, Canadian Pacific and Hudson Docking and Terminal Company, which intends to construct a road from Ogdensburg through the States of New York and New Jersey to the Newark and New York bays, has under advisement a proposition from the General Electric Company to equip the line with electric locomotives which are to haul the trains at the rate of 100 miles an hour.

A part of the plan is that the General Electric Company is to furnish electric light to all the cities and towns through which the railroad passes and also furnish power to manufactories.

Electricity in Agriculture.[*]

Influence of the Electric Current Upon Vegetation.

The influence of atmospheric electricity in the propagation of plant life has long since been recognized. Attempts, however, to solve the problem of the exact relations existing between this natural force and the growth of plants have been numerous, it is true, but invariably futile. The ill success attending these efforts naturally turned the attention of scientific agriculturists to another quarter—to the possibility of experimenting with batteries. Widely differing results have been published, and it has followed that neither the favorable nor the unfavorable influence can be said to have been clearly established. So far as the German experiments go, the substance of most of them shows results decidedly adverse to electricity—at least to its employment as a practical factor.

As early as 1859 one Helmert conducted a series of experiments with pine-tree seeds, peas, and lettuce. At one end of the planted area a plate of copper was sunk into the soil and at the other end one of zinc. The plates were then connected with an exposed copper wire. This method of introducing the current, I may say in passing, is usual. A more even and early germination of the pine seeds followed, though no acceleration in growth was perceptible. The peas and lettuce showed the beneficial effects in healthier leaves and blossoms and in improved fruit.

About two years later Fichtner, in exactly the same way, obtained the most brilliant results, as the following table shows:

Variety.	Yield of fruit per Austrian Joch.[*]		Straw.	
	Usual culture.	Galvanic culture.	Usual culture.	Galvanic culture.
	Pounds.	*Pounds.*	*Pounds.*	*Pounds.*
Barley.........	2,048.2	2,935.2	3,290.7	5,187.8
Peas...........	2,523 3	3,085.4	3,349.1	4,407.7
Summer wheat	1,482.8	2,317.3	4,778	4,839.2
Buckwheat....	425.7	967.3	5,782.9	6.771.1

[*] 1 Austrian Joch = 1.422 acres.

The increase in the yield by electrical culture was from 16 to 127 per cent. higher than by ordinary culture. This experiment, however, was not considered of much value, because the ground electrized was laid with so-called air-drains, which had a favorable influence on the moisture of the soil, while the ground in an ordinary state of cultivation was not so drained. In order to observe the power of electricity to resolve the component parts of the soil, two samples of the latter were taken, one of which was subjected to an electrical stream for two weeks and the other left untouched. At the end of the time mentioned 100 grams of each sample were mixed with 1,000 cubic centimeters of water, and it was found that 0.135 gram of the electrized earth and 0.085 gram of the non-electrized soil were soluble.

Blondeau experimented with an induction, instead of a constant stream, and noted marked effects upon seeds and fruits. The latter ripened earlier, and apples, pears and peaches at once mellowed under the influence of the current. Pea, bean and wheat seeds were soaked in water to give them conductibility, then subjected to an induction stream lasting several minutes, and afterwards sown in selected garden soil. These seeds germinated much earlier than the others. Further, the growth of the plants was quicker, and their leaves and stalks stronger and of a darker green.

More recently (1882) Tschinkel called attention to the propitious influence of electricity upon plant growth. His tests showed a difference of from six to eight days in favor of the germination of seeds planted in soil through which the electric current had circulated. The plants also had a quicker and healthier growth. The observations of the experimenter led him to attribute the favorable influence of electricity to the decomposition of the salts and other component parts of the soil.

On the other hand, Prof. Wollny, of the Royal Technischen Hochschule, in Munich, obtained results of a distinctly different character. Dr. Wollny has collected in various publications most of the investigations that have been made, and his interest in the subject led him to conduct an independent series of experiments at the time of the International Exposition at Munich.[*] For this purpose two wooden boxes with glass covers were taken; they were 20 centimeters high, of like width, and 80 centimeters long. They were first filled with a like quantity of moist and carefully prepared garden soil. Next, at both ends of one box a zinc plate was sunk deep into the earth and connected with the pole of a battery consisting of 10 Meidinger elements. Further, both boxes were sown crosswise with a great variety of seeds—radish, barley, wheat, mustard, sunflower, etc.—and in such a way that the rows and plants were at equal distance. The plants under the influence of the electric current sprang up later and showed a much more uneven and feebler growth.

Perhaps the first experiments to be undertaken on a really extensive scale were those conducted by Prof. Holdefleisz in the summer of 1884 on the Wangern farm, near Breslau, and reported in the *Magdeburger Zeitung* the following year by Prof. Märcker.[†] Two theories are tenable to account for the influence of electricity: (1) Electricity affects plant growth in much the same way as other natural forces, as light and warmth; (2) it acts as a solvent and decomposes the component parts of the soil, especially salts, thereby enriching it. This influence may be established in two ways—the positive and negative. With regard to the negative method, if the electric forces in the atmosphere are beneficial to plant growth, it follows that an abnormal and unfavorable change would at once be perceptible if electricity alone of the natural forces could be excluded. The French agricultural chemist Grandeau succeeded in accomplishing this by means of an ingeniously contrived iron cage. The other natural forces were, of course, left in full play. The result was that the plants, deprived of their natural electricity, were very backward in their growth. The positive method —adopted in the Wangern farm experiment—consists, as would be implied, in the introduction of electricity by artificial means.

Prof. Holdefleisz had already observed the favorable influence of electricity on plants isolated in boxes with glass tops, but had very grave doubts as to whether it could be employed to advantage in the open field. In order to make the test, a beet-sugar field was selected with the plants already above the ground and in an even state of cultivation. The rows were planted from east to west. Copper plates 50 by 80 centimeters were sunk to a depth of 50 centimeters and in such a manner as to cover the width of two rows. The plates of each pair were 56 centimeters apart and connected through insulated wires with the positive and negative poles of a battery of 14 Meidinger elements. In still other rows electricity was generated without a battery. Copper and zinc plates were in the manner above described placed at a distance of 33 meters from each other and connected with wire. In order to increase the strength of the current, pairs of copper-zinc plates riveted together were sunk at regular distances between the two end plates, so that the following order was preserved: Copper, zinc, copper, zinc, etc. The same plan was followed with a field of potatoes. The experiment began on May 20 and was continued uninterruptedly the entire season. The following observations were taken:

The existence of the current could be detected during the entire summer.

With the aid of a delicate electrometer, the presence of the electric current could be established in the parcels between each pair of plates.

The rows with the battery plates did not differ during growth from those of other fields.

On the other hand, the rows with zinc and copper plates began about ten days after the commencement of the experiment to have a fresher and healthier appearance in comparison with the average of the other fields. This appearance continued as long as the tops were growing; from the middle of July, however, no further difference could be seen.

The crop grown under the influence of the battery current was in no way unusual, either in quantity or quality.

The yield of those rows with the copper and zinc plates showed a marked increase—15 per cent. in beets and 24 per cent. in potatoes.

No difference in quality was in any case demonstrated. The percentage of sugar contents fluctuated from 14.3 to 14.5; the average starch contents of the potatoes was 21.5 per cent.

The experimenter, while not regarding the test with copper and zinc plates as conclusive, considered it significant in view of the largely increased yield, and also as practical in view of the trivial cost of the necessary apparatus.

Prof. Holdefleisz's experiment was followed with great interest. One immediate result was to induce Oberamtmann Braune, of Biendorf, to undertake a series of tests along the same lines.[*] Seven rows of beets already above the ground were selected, each row 56 meters long. The two outside rows right and left were subjected to electrical influences in precisely the same manner described in the Holdefleisz experiment. A simple current generated by copper-zinc plates was applied to the two outside rows on one side and a 14-Meidinger-battery current to the two outside rows on the other. The battery was buried in a substantial wooden box to the same depth as the plates (65 centimeters). The three inside rows were left neutral. The experiment began on June 3, and was continued until the crop was harvested. No perceptible variation in the growth of the leaves or in the general appearance of the plants was at any time remarked.

The crop began to be harvested on October 26 and was at once analyzed with the following results:

Description.	Weight of beets per morgen.[*]	Polarization.			
		Brix	Sugar	Non-sugar	Quotient
	Centners[†]				
Simple current.	230	18	15.3	2.7	85.6
Battery current	235	17.9	15.5	1.4	86.6
Without electricity........	210	16.7	15	1.7	89.7

[*] 1 morgen = 0.63 acres. [†] 1 centner = 112 pounds.

These results in general confirmed those of Prof. Holdefleisz, both as regards quantity and quality. There was an increase in the yield of those rows subjected to the electric current—20 centners in the rows where copper and zinc plates were used and 25 centners where the battery was employed. On the other hand, with reference to the quality, the slight increase of 0.5 and 0.3

per cent. in the sugar contents was regarded as too small to have any significance whatever.

But by far the most exhaustive experiments of all have been conducted by Prof. Wollny, whose special work in this field has already been referred to. The first of his series of tests took place in 1883 and was conducted on a rather limited scale.* Five garden plots were selected, each 4 meters long and 1 meter wide. There was a space of 1.2 meters between the plots, and they were all cut off from each other by planks sunk to the depth of 25 centimeters. Zinc plates were sunk to the same depth at each end of the three plots and connected with batteries by means of copper wires. In plot IV two copper and zinc plates were connected by a copper wire 1.5 meters above the soil; plot V was left untouched. A constant current was kept up from first to last. It was regulated by a galvanometer, and whenever the stream began to grow weaker the elements were renewed. This happened every three or four weeks. The current generated by the copper and zinc plates was weak compared with the others. The soil was everywhere in the same state of cultivation, and was composed of a calcareous sand 24 centimeters deep and resting on a vein of limestone. Further, each plot was divided into four sections and planted on May 2 with summer rye, beans, rape seed and potatoes.

In this manner each variety came under all the influences at work. The length of time taken in the germination of the seeds is shown in the following table:

Description.	Number of kernels.									
	May—									Total.
	7	8	9	10	11	12	13	14	15	
Summer rye:										
Induction stream	35	..	1	..	2	1	..	1	..	40
6 Meidinger elements	35	..	..	1	..	3	1	..	1	41
3 Meidinger elements	37	2	1	..	1	..	..	..	..	41
Copper-zinc stream	41	..	..	..	..	..	..	..	..	41
Without electricity	36	..	..	1	2	..	1	..	..	40
Beans:										
Induction stream	6	27	8	..	..	..	..	..	1	42
6 Meidinger elements	14	18	6	1	..	..	1	..	..	40
3 Meidinger elements	7	23	10	1	..	..	..	..	..	41
Copper-zinc stream	6	21	10	4	1	..	..	..	..	42
Without electricity	5	19	9	5	..	1	..	1	..	40
Rape seed:										
Induction stream	36	..	..	..	..	..	..	..	..	36
6 Meidinger elements	36	..	..	1	..	1	2	..	..	40
3 Meidinger elements	37	1	..	2	..	1	..	1	..	42
Copper-zinc stream	34	..	3	..	..	..	..	..	..	37
Without electricity	36	..	..	..	..	..	..	..	..	36

No variation in the germination of the seeds or in the growth of the plants was observed, and in almost every case the yield of those plants affected by electricity was considerably under the normal crop. The potatoes alone, grown in the sections where the copper-zinc stream was applied, showed an increase of 6 per cent. in the quantity and a slight improvement in the quality. This demonstrated evidently that the limit to which electricity might be applied with favorable results had been exceeded, and pointed to the advisability of using weaker currents by a repetition of the experiments.

The tests were next continued in 1886 and 1887. The plots selected were larger than those taken for the trial of 1883. Four rows were reserved, each 16 meters long, 2 meters wide, and separated from each other by a distance of 1.2 meters. Each row was divided into eight sections of 4 square meters. The soil, which was in part artificially built, had a depth of 30 centimeters and rested on a limestone foundation. It was harrowed in the spring of 1885 and again in the spring of 1886. Each section was fertilized with 200 grams of guano in 1886 and 400 grams in 1887. The manner of establishing the electric current was the same as before described. A different variety was planted in each one of the eight sections of the four rows and in corresponding sections. Weeds were carefully kept out. The strength of the current was ascertained every fortnight by means of the galvanometer, and the stream renewed whenever necessary. The copper-zinc current was very weak, the needle never registering at maximum more than 3° or 4°, while the Meidinger-battery current was somewhat stronger (12° maximum). This last was much weaker than in 1883. As in the preceding experiments, the germination and growth were alike.

Convinced by the results obtained from these experiments that the direct influence of electricity upon plant life was at best negative, and in most cases harmful, Prof. Wollny next turned his attention to an investigation of the indirect effects, i. e., the decomposition of the organic and inorganic substances of the soil. A given quantity of soil, selected with due care, was put into U-shaped glass tubes and subjected to various complicated processes. The proportion of carbonic acid generated in all the tubes, whether electrized or not, was well-nigh constant and pointed to the conclusion that the organic properties of the soil were in no way affected by the induction or galvanic stream. The experiment was continued long enough to furnish data with which to generalize.

So, too, with regard to the solubility of mineral properties, the tests made showed very little variation. The results are less reliable because of the difficulties surrounding the experiment. The soil was put into glass cylinders, and, after the conclusion of the experiment, upon analysis of 1,000 parts of dry soil, the following proportions were found to be soluble:

Description.	Kali.	Ammonia.	Phosphoric acid.	Spirits of niter.
Electrized	0.040	0.006	0.008	1.068
Non-electrized	0.085	0.010	0.015	0.077

To sum up, then, the question of the propitious or unpropitious influence of the induction or galvanic stream upon plant life has found in Germany, up to the present moment, no real practical solution; nor is one believed to be easily possible. While it is true that some few isolated experiments have been highly favorable to electricity, those conducted on the most extensive scale have resulted in very indifferent success. For the rest, it is evident that the obstacles in the way of locating with any exactness the point where the favorable influence stops and the unfavorable begins are too great, and a practical regulation of the current is scarcely to be hoped for.

An Argument for Municipalization.

Dislike the fact as we may, the fact remains that we are rapidly traveling along the "checker'd paths" leading to complete municipalization—whether the roads run uphill or down we leave it to experts to prophesy and events to decide. The Glasgow Corporation, not content with having municipalized the water, gas and electricity supply, now contemplate applying to the Postmaster-General for a license "to supply the community with an efficient telephone service." A municipal telephone service is an experiment worthy of a trial—north of the Tweed. Even in the far East, local authorities have caught the infection. At the last meeting of the rate-payers of the foreign settlement north of the Yang-king-pang, a resolution in favor of buying out the local electric lighting company was carried by two votes, a majority having apparently been obtained by the Yang-king-pang argument that as there was a municipal *abattoir* there ought also to be a municipal central lighting station.—*Electrician*, London.

Frequency in Transformers.

Some years ago there was a very unprofitable discussion, says *Industries*, as to the relation between the dimensions and output of a dynamo. Professors multiplied the linear dimensions of phantom dynamos by *n*, and found the output was various fractional powers of *n* times that of the original phantom before they had tampered with it. The discrepancies were numerous, but they were all due to electricians assuming different conditions. The dynamos might be compared if designed so as to give the same efficiency, or the same final temperature. The copper might be run at the same current density, or the magnets at the same induction. If the same induction were employed, the armature of the large machine, when enlarged to scale, had too many ampere turns, and so on. Then again, the larger machine could not reasonably be expected to run at the same speed, so it had to go either with the same factor of safety or the same peripheral speed. Hence there were so many ways of comparing the machines that the results of the calculations did not agree.

We are now threatened with a similar pseudo-scientific epidemic with regard to transformers and frequencies. Mr. Steinmetz calculates that the output of a transformer varies as the three-eighth power of the frequency. Obviously, if a transformer of a given size is to be re-designed with the same weights of iron and copper for, let us say, increase of frequency, it may be designed to give an increased load at the same efficiency, or with the same percentage drop, or with the same total rise of temperature, or with the same light load efficiency, and it will have a different output in each case. Again, there is no reason why in the comparison we should adhere to the same weights of copper and iron. We might vary them, keeping the total weight or total cost the same. We thus have at once pointed out twelve different laws of the relation between the output and frequency of a transformer. If other comparisons are made, such as the same bulk with different weights of copper and iron, and if allowance is made for the relatively smaller volume of insulation on a high-frequency transformer, we obtain still more laws. It is therefore sincerely to be hoped the unpractical electrician will not flood the technical press with calculations as to the relations of output and frequency. He has so far spared us the discussion of the output of a phantom curve of sines for a transformer whose dimensions have been multiplied by *n*. Such calculations are quite useless.

A New Application of Photography.

Perhaps the most recent application of photography which has come to play quite an important part in scientific work is a registering device for recording a continuous reading of station voltmeters.

The apparatus is described as follows: An incandescent lamp is arranged so that the rays of light which emanate from the glowing filament are directed in a parallel sense upon a narrow slit, before which is placed the needle of the voltmeter. Obviously, in moving across this illuminated slit, the needle obscures the light and the shadow is then recorded upon the sensitized paper as a white image upon a dark ground (the image of the illuminated slit). By an ordinary clockwork mechanism the sensitized paper, which is rolled upon a drum, is caused to move at a regular rate, and the intervals of time are recorded upon it photographically at the same time as it receives the shadows of the moving needle.

Among the bills signed by Governor Flower last week was one authorizing a village to contract with electric light companies in an amount not exceeding 2½ mills for every dollar of taxable property within such village each year.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:
UNITED STATES, - - - - - $2.50
IN CLUBS OF FIVE OR MORE, - - - $2.00
FOREIGN COUNTRIES, - - - - - $4.50

ADVERTISING RATES:
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.
Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Candle Power of Arc Lamps. The conventional manner of rating arc lamps at present in vogue has been the foundation of numerous law suits and continual disputes between central station managers and customers, and is again called to mind by the recent candle power tests made in Buffalo by the City Chemist at the instance of the Board of Public Works. In this case it was found that the average of all the lamps tested was 786 candle power and in some lamps the tests showed less than 250 candle power, which, if correctly determined, point to the folly of attempting to rate arc lamps according to a photometric standard.

Without reference to this particular case, with whose merits we are not acquainted, it is well known to electricians, though unfortunately not to the public at large, that the 2,000 candle power standard which was adopted in Paris in 1872 is an entirely arbitrary one which it is impossible for any company to realize in a literal sense with any of the systems in use to-day. It is safe to assume that not an arc lamp in use for street lighting maintains its candle power constant at any figure for more than a few minutes, and this is inevitable owing to the nature of the mechanism by which these lamps are regulated.

From the standpoint of the customer whose object is to secure a certain amount of illumination and who contracts for a lamp of a definite power a photometric standard is desirable as he pays for the light furnished and is not concerned with the amount of energy supplied to the lamp. Contracts are invariably made on the basis of the 2,000 candle power standard, and wherever an attempt to interpret this literally is made trouble is sure to ensue. Central station men are entirely aware of this discrepancy but use the term 2,000 candle power in conformity with the standard adopted by the manufacturers of arc lighting apparatus.

In all of the arc lamps in general use the amount of illumination depends upon the length of the arc between the carbon pencils when the lamp is supplied with its normal current—generally about ten amperes at forty-five volts. The arc established by this current is maintained at the expense of the carbons, especially the positive one, which is gradually consumed. To keep the length of the arc constant, various mechanisms are employed for feeding down the upper carbon, and as the consumption of the carbon is irregular, depending on the fluctuations of the current and the variation in the density of the pencils, the feeding mechanism must be controlled automatically by the current according as the resistance of the arc varies.

In principle, therefore, the regulation of arc lamps is analogous to regulation by a fly-wheel, whose action depends on a certain amount of fluctuation in the machine which it governs, and for this reason an invariable standard of candle power is unattainable. These lamps vary in their efficiency, the candle power being maintained most nearly constant in those which respond the most readily to any fluctuations.

The impracticability of the present standard has become so apparent that a new standard is to be determined by the electrical convention in Chicago this summer. The most feasible suggestion appears to be a standard number of watts supplied per lamp of a definite minimum efficiency in watts per candle power.

* * *

Electricity in Agriculture. The use of electricity in agriculture, both as a motive power for farm machinery and a means of forcing plants by its direct application to the soil, has been reported upon by all our foreign consuls for their respective districts, and the facts appear to be that beyond a few experiments its use is unknown for either purpose. The tendency to apply electricity to every conceivable operation has led to a few experiments in the direction of its application directly to the soil in which plants are raised, but in Germany, where the only systematic attempts at this are reported, the results seem to argue against it, as, aside from the expense it involves, the current in most cases proved detrimental to the plants.

The cases quoted from the report of Commercial Agent Washburn, printed elsewhere, are the only notable ones mentioned, and they show such contradictory results that it is impossible to draw any general deduction from them except the fact that the expense of applying the current in this way far exceeds any benefit derived from its use.

The driving of agricultural machinery by electric motors is equally unknown in most places, and its introduction, like that of steam for this purpose, would be worse than useless on a farm of the usual size, as the interest on the plant during the eight or nine months when it would stand idle would undoubtedly overbalance the profits earned in three or four months of use.

It is also apparent from these reports that even if cases of the beneficial effects of either the application of the current or of electric light to plant growth could be verified, the difficulty involved in its extensive application would always preclude its adoption to any practicable extent.

* * *

WE PRESENT our compliments to the *Electrical World* for its publication of a thoroughly interesting account of the proceedings in the Columbia lamp case at St. Louis a week in advance of its contemporaries. The *Electrical World* is justified in taking credit to itself for this achievement.

The public, however, has a better memory than the enthusiastic editor of our esteemed contemporary, and has not forgotten that when the Goebel defense was first introduced by the Beacon Company at Boston, when it was brand new and a genuine sensation, the *Electrical World* shared with the *Electrical Review* and the *Electrical Age* the honors of the tail end, being exactly ten days behind its more progressive contemporaries, ELECTRICITY and the *Electrical Engineer*, in printing the facts in this remarkable case. Go to.

* * *

THE truth of T. Carpenter Smith's remarks at the St. Louis Convention has been amply demonstrated by the rush of orders which are coming in to the independent lamp factories.

"Sugar If Necessary." The efforts of the Trust's central station managers in Detroit to keep their grip on that city, which have finally culminated in the arrest of Manager Fitzgerald for bribery, are related in some detail in another column.

The story brings to mind the historic telegram sent by Mr. Richard Tricky McDonald to one of his agents in Indianapolis a few years ago.

This agent's name was Smith, and he had been endeavoring to close a contract for the city lighting. A majority of the aldermanic committee had not yet been converted. He wired Mr. McDonald for instructions.

There happened to be another Smith interested in the matter—a member of the Board of Aldermen and an opponent of the Ft. Wayne scheme. It was this Smith who, by accident, received the telegram in answer from Mr. McDonald, and he failed to keep its contents secret. It read :

"Sugar If Necessary."

If the investigating committee of the Detroit Council is thorough enough, it will perhaps learn that Mr. Fitzgerald was only obeying the orders of his chief.

It is needless to point out that such methods are a disgrace to the electrical fraternity from which the trade at large must suffer.

The proceedings in Detroit are added justification for the course pursued by ELECTRICITY.

We shall continue until the policy of the General Electric Company, and its executive officers, have been entirely changed, or until it is thoroughly known to all men that it is not a representative electrical concern, and that it is in direct hostility to the honest and legitimate Electrical Industry of America.

* * *

Alternating Current Power Distribution. A paper by Mr. Albion T. Snell on the subject of the distribution of power by alternating currents is commenced in this issue and is of special interest at present, in view of the demand which exists for motors of this description and the numerous attempts which are being made to produce an efficient machine of this kind.

The paper deals at considerable length with all of the types of alternating current machines which have been put upon the market, although in most cases it must be admitted that these motors have not proved of much practical value except for very small powers. The utilization of large water powers such as the Niagara Falls project, or the consumption of coal at the coal fields, as has been proposed in England, for the distribution of power by electricity, has many points which commend it to favor, yet every long distance transmission scheme must depend upon the alternating current where powers of any considerable size are involved.

At the present time the multiphase alternating systems appear to give the most immediate promise of success, and although the simple synchronous single phase motor is capable of efficient use in many cases it has been found wanting at least in the experience of central station practice.

The only thoroughly practicable system for distant transmission must be one from which both light and power may be taken, and Mr. Snell's paper points out the difficulties which must be overcome in order to secure this result efficiently.

* * *

COLUMBUS was a daring man,
Worthy of lasting fame—
His caravel had no dynamo,
But he got there just the same.

* * *

THE CITY of Detroit is now ready for the purchase of a large outfit of electrical apparatus, and honest men will have a show.

* * *

SINCE our last issue, showing by their own figures the results of the first eight months' business of the Electric Trust, their stock has dropped to 94¼.

* * *

ELECTRICITY first opened the eyes of the officials of the city of Detroit to the fact that their city was in the hands of a grasping and thoroughly unprincipled electric lighting monopoly.

* * *

THE Mayor of Detroit to the Mayor of Syracuse: "It is *not* a very long time between bribes."

* * *

THE pages of ELECTRICITY have sparkled with TRUTH in the past eight months; and the truth is not yet half told.

* * *

MAYOR PINGREE'S Investigating Committee should understand that W. H. Fitzgerald is only a tool. If they seek the fountain head of the opposition to the will of the voters of Detroit, the Director General of the corrupt combine, they will find him not in Detroit nor in Michigan, but not fat from Fort Wayne, Indiana, U. S. A.

* * *

WE ARE informed on good authority that Messrs. Schuckert & Company, of Nuremburg, Germany, have decided to follow the example of Siemens & Halske in establishing an American branch. The arrangements are said to be completed, and the American company will be backed by millions of capital, both German and American.

* * *

WE ADVISE the officials of the Trust not to visit the Fair. The whirling of the Eddy motors will be sure to make them dizzy, and the dazzling rays from the Standard arc lamps and the Westinghouse incandescents would probably produce several cases of blind staggers.

* * *

OUR SYMPATHIES go out to the Edison licensees. Their luck is hard.

* * *

"SUGAR if necessary" has no place as a watchword in honest business.

* * *

THAT hen is off, and the fighting game cock is Novak. May he win many battles.

Personal.

Mr. K. J. Sunstrom, chief engineer Stora Kopparbergs Bergslags Aktiebolag, of Stockholm and Falun, Sweden, has just arrived in Boston, where he will devote a week in studying the machines and process of the Electrical Forging Company.

Trusts.

A Philosophical Dissertation.

There has for several years manifested itself in the commercial and manufacturing interests of this country a tendency for centralizing or concentrating their productive resources with a view of controlling the entire output of certain industries and thereby direct the public market. Such manipulations are now popularly known as combinations or trusts.

One of the most prosperous and successful enterprises of this character is the Standard Oil Trust, and there are very fair reasons for the assumption that the very success of this corporation has been an impetus for numerous attempted imitations and emulations, the aims of which, however, were not equally resultant in profit and success. Why these different results, will be seen later on.

The fundamental principle governing the idea of the modern commercial combinations or trusts is as old as the world itself, and is merely a modification, or a new and different application, of the old saw, where the individual usurps the rights and power of everyone else.

We find the principle of commercial trusts carried out in all countries ruled by an autocratic government. The Czar of Russia, for instance, is the personification of a political trust, who assumes the rights, the privileges and the power which in reality belong to his many millions of subjects.

Thus we see that the inherent principles involved in the system and methods of commercial trusts are most palpably and flagrantly opposed to the principle of Americanism; and yet inexplicable as it may seem, we find that the commercial ground of this country has been more fertile and conducive to the generation of these parasites than any other country. Owing to this fact, however, that trusts have become most prolific in an element totally foreign to their nature, it may be justly prosumed that their existence is merely transitory. They have been reared by commercial minds of a character diseased and absolutely devoid of the ethics of true morality; and while even under such conditions it may be possible to achieve commercial success, this success can only be of temporary duration. Hence we may state that American commerce is now migrating through an era of trusts, but it will be nothing more than an era, and for the reputation of our nation's commerce it is to be hoped that it will be succeeded by something more ennobling.

Enumerating all the different trusts of to-day, and looking at the list from the Standard Oil Trust to the Electric Trust, we may divide them into two classes. One comprises commercial combinations formed for the control of natural products, and the other for the control of manufactured products.

Of these two, the former kind is not so difficult to manipulate towards a successful issue as the latter. In the first place the object in view can be attained by the mere consideration of purchase price only, and hence the question of money is the chief one involved. For instance, to control the oil market the possession of the largest amount of fields of producing oil wells successfully corners the entire business. To form a lead trust, the combination which controls all or nearly all the producing lead mines is in a fair position to dictate prices.

It is similar with a copper and silver trust. A wheat trust, however, would only be permanently successful by a controllership of all the wheat-growing lands of the country.

According to the measure in which such a controllership is completed, the operations of the trust are more or less successful. Because the

Standard Oil Company owns practically all the crude oil produced in this country, its control of the market is supreme.

There have been many pleas of justification for the existence of trusts brought forward; mere discussion of such a thing is purely waste of time. You cannot wash the devil white, and even the greatest argumentative talent of modern times will not be able to produce evidence and facts to upset this truth—that the principle which assails the fundamental laws of human independence of action, and attempts individual usurpation of a force rightly belonging to all, is attacking the laws of nature, and therefore must be essentially wrong.

Supposing that there were in existence to-day the Standard Water Company, owning and controlling all the wells, rivers, lakes, in fact every drop of water in this country, does any one mean to aver that such a monopoly could justify its right of existence, even were this company to distribute the water free to the public. No! though it might be true that the water would be free to everybody, yet this freedom would only exist by the grace of the Standard Water Company, and since that corporation was controlling something which by the laws of nature should belong to all, the principle of the trust still finds its application, and it is safe to venture the assertion that under the above described condions the peotip by ulle wod arise in a bodandreak up the Standard Water Company. There is a vein of independence of action in human nature which rebels at doing certain things at the bidding of somebody else, whether it be to drink water, to buy kerosene oil, lead, copper, sugar, or electrical apparatus, and therefore any individual or organized body of individuals banded together for the purpose of compelling the distribution of any product, natural or manufactured, according to their dictation, will soon find itself undertaking a task beyond the capacity of human nature.

Viewing the formation of trusts it becomes at once evident, whether the aim is to control the natural or the manufactured product, that a successful issue can only be arrived at by obtaining possession of the source of supply, and as these sources are of larger or smaller number, in the same ratio increases or diminishes the difficulty of success. And while the range of these sources of supply in the natural product can be much easier calculated than in the manufactured product, it is also evident that in the same proportion the formation of a trust for the control of the manufactured product is much more difficult.

Take the Electric Trust, being of the most recent birth, and let us look at the many obstacles there are, insurmountable ones at that, which make it the most flimsy attempt in the history of trusts, and one which will never be any more successful than the attempt to form a drinking water trust.

The electrical industry has, in a few short years, risen to the eminence of one of the greatest fields of commercial enterprise in the world. Its sources of supply are manifold. Attracted by large profits in the business, manufactories have been established everywhere, equipped with first class electrical talent, good machinery and backed by unlimited capital. To control all these hives of industry and concentrate them under one great body would cause the cutting off of a good many bright, ingenious, energetic heads. Now these men bereft of their former fields of operation, have not lost any of their ambition, their intellectual abilities or their energy, and they will immediately look around for a field where their ability finds again the same scope it formerly enjoyed. In other words, new companies will constantly spring up, and the great Trust would again and again be confronted with fresh rivals, and while they might be insignificant at their inception, their growth is very probable. Hence we find that one source of supply to the electric industry, the ingenuity of human brains, the control of which is essential in the successful operation of the Electric Trust, it is very difficult to pürchase.

Another obstacle, and also a very formidable one, which is involved in the absorption of the smaller electric manufacturing companies, is the difficulty of inducing the owners of the smaller concerns to give up their independence and allow themselves to be subjected to the dictations of a trust. True, money talks, and most men have their price, but the smaller houses number many, and there are some of them operated by men who prefer to run their own works at a small profit rather than accept the proposition of a combination, even at the prospect of personally enriching themselves. Fortunately also for the electric industry of this country, it has a very good representation in the press, and while hitherto the voice of independence has only found its clarion notes in the columns of ELECTRICITY, that voice has nevertheless been a very strong one, and more than once have its echoes sounded like funeral dirges to the General Electric Company. That the other papers will have to follow in the wake of ELECTRICITY is merely a question of time.

Finally we come to the rock upon which the sinking ship of the electric combination is bound to shatter. This rock is the great aggregation of purchasers of electrical apparatus. The manifestation of their opposition is two-fold. The first is the spirit of independence innate in every true American who has an inborn hatred to submitting to dictation. This is a point mentioned above, and it is one of the greatest importance in this case, because the purchasers of electrical apparatus, such as the directors and managers of electric lighting plants, are most wide awake business men, men of affairs and men of financial education. Then comes the point that it does not take these men long to realize that the establishment of an electric combination controlling the manufacture of electrical apparatus will place them in a dependent position. It will not be any longer a question of buying such apparatus as suits the central station men, but of buying what the Trust chooses to sell them. It will not be any longer a question as to getting the benefit of competition, but of paying the price the Trust chooses to make. For these reasons these men are even now looking upon the machinations of the Trust with a spirit of antagonism. Many of them have openly declared that they will buy electrical apparatus from anybody in preference to purchasing from the General Electric Company, a fact which makes the opposition of the smaller manufacturing companies much easier.

Take it therefore all in all, the existence of trusts is on the decline. The trade has been awakened to the fact that competition, the soul of all business, is being attacked. The public is being aroused, and is beginning to realize that one of its dearest prerogatives, the spirit of independent action, is sought to be annihilated.

Our houses of legislation will be prompted to action, the National Government will take a hand in the pernicious activity of combinations, which cannot help but are sapping away the true greatness of our national commerce, and we may confidently look forward to an early dawn, which will show the firmament of America's commer cial sky unsullied in the clear light of fair dealing, and offering a chance for every honest enterprise.

PHILOSOPH.

COMMUNICATIONS.

No Summer Meeting.

To the Editor of ELECTRICITY.

At a meeting of the Executive Committee of this Association, held to-day at this office, it was decided that the Association would hold no convention the coming summer.

Very respectfully,
GEO. F. PORTER, Secretary.

Office of National Electric Light Association,
New York, April 27, 1893.

A Correction.

To the Editor of ELECTRICITY.

In the issue of your esteemed journal of April 19th last, referring to M. D'Arsonval's statements that criminals and lower animals are not killed by dynamic electricity, but are rather thrown into a sort of trance, you write that these views "are supported" by me in an interview appearing in the New York *Sun*. If you will kindly again refer to that interview you will see that my contention was *not* that the animal (criminal or otherwise) was not killed as D'Arsonval states, but that I knew of no way of settling the horrible doubt he has raised as to whether the subject was not actually killed upon the autopsy table by the surgeon's knife except in such cases to defer the autopsy and await the signs of death due to decomposition. I also carefully stated reasons in the interview why I believed that the abolition of consciousness was instantaneous, and death equally instantaneous.

The answer to M. D'Arsonval is a very simple one, viz., defer the autopsy until signs of putrefaction appear. This is the point I tried to emphasize.

Yours very truly.
WILLIAM J. MORTON.

The Stanley-Kelly Motor.

To the Editor of ELECTRICITY.

In connection with the article on the Stanley-Kelly motor in your issue of the 26th inst., allow us to say that throughout the development of our system we have received great aid from all our associates, and that we are indebted to them for valuable suggestions, especially so to Messrs. C. C. Chesney and W. B. Tobey.

WILLIAM STANLEY, JR.
JOHN F. KELLY.

SOCIETY NEWS.

Chicago Electric Club's New Officers.

At the annual meeting the following named officers were elected for the ensuing year:

President, J. P. Barrett; 1st vice-president, F. W. Parker; 2d vice-president, E. Baggot; 3d vice-president, F. W. Cushing; 4th vice-president, Geo. Cutter; secretary, F. L. Perry; treasurer, J. W. Johnson; managers, F. W. Horne chairman, L. A. Ferguson, S. A. Douglas, M. A. Knapp, J. W. Buckley, E. C. Ferguson, C. T. Page, A. S. Terry, Ben. Williams, L. S. Hills; membership committee, C. C. Haskins, T. G. Grier, D. G. McDougall; house committee, T. B. Badt chairman, F. E. Degenhardt, H. P. Lucas.

California Electrical Society.

At the last meeting of the California Electrical Society, held April 17, a paper was read by Mr. Geo. P. Low on "What the Electrician Finds of Interest in Southern California," illustrated by photographs.

The officers elected for the ensuing year are Geo. P. Low, president; C. O. Poole, vice-president; Max Caspari, secretary; H. T. Bestor, treasurer.

TRUST METHODS.

The Manager of one of the Trust's Central Stations Under Arrest.

BRIBERY IS CHARGED.

The Detroit Combine Appears to be Broken.

William H. Fitzgerald, Secretary and General Manager of the Detroit Electric Light and Power Company, was arrested on Tuesday, the 25th of April, on the charge of attempting to bribe an alderman.

The charge is preferred by Alderman Protiva, who claims that Mr. Fitzgerald went to his house at 5 o'clock on that day and offered him $1,000 for his vote in the Common Council on all matters pertaining to the Detroit Electric Light and Power Company.

Alderman Protiva has testified that he pretended to accept the offer, and that Mr. Fitzgerald paid him $200 in cash, and promised to pay him $200 the next day and the balance at some time in the future.

During the session of the Common Council the same evening Mayor Pingree produced the roll of bills, which he waved dramatically in the air as he told the story of Alderman Protiva's accusation. The money was that which Alderman Protiva received from Mr. Fitzgerald.

City Prosecuting Attorney Frazer has charge of the case, and says he has been watching the movements of Mr. Fitzgerald and certain aldermen for weeks with this move in view. He was well informed as to the day for the boodle to be paid out.

Readers of ELECTRICITY are familiar with the progress of events in Detroit lighting matters during the past six months.

A few years ago, when an act was passed by the Michigan Legislature enabling towns and cities to erect municipal plants, cities above a certain size were excluded through the efforts of the Fort Wayne Company.

Recently, Mayor Pingree, of Detroit, backed by large numbers of the representative business men of the city, succeeded in getting this limitation removed by the Legislature. The intention was to build a municipal plant for the city of Detroit, provided a reasonable contract could not be secured with the Detroit Electric Light and Power Company.

The final authority for proceeding with the city plant must come from the Board of Aldermen.

A resolution had been offered by Alderman Vernor, shrewdly worded, but which would have had the effect of killing the municipal plant, for which the citizens of Detroit had voted by an overwhelming majority. Mayor Pingree had vetoed this resolution. The necessary votes to override the Mayor's veto were not to be had honestly, and it is said the sum of $25,000 was to be devoted to procuring these votes.

Alderman Protiva, acting in accord with the Mayor, received Manager Fitzgerald graciously, and accepted his first instalment of $200 on the spot.

At the Council meeting later in the evening the question of the Mayor's veto came up, and it was soon apparent that something had happened. A majority was in favor of sustaining the veto, and there was a scramble among the Mayor's opponents to get their votes changed.

Mayor Pingree finally asked permission to make a few remarks, and drew from his pocket the $200 in bills which Fitzgerald had paid to Protiva three hours earlier. The money was turned over to the President of the Board, and an investigating committee was appointed.

Mr. Fitzgerald spent the night in the station-house, and was released on $5,000 bail the next day.

Prosecuting Attorney Frazer is quoted as follows:

> "I have been keeping tab on those fellows for weeks. I have been keeping track of every move they made. They commenced shoving out the boodle on the 25th. There isn't the slightest question about the money being given to Alderman Protiva. Fitzgerald said he would have given him more than the $200 if it had not been after banking hours."

To Be Reopened.

The Sunbeam Lamp Case in Court.

The Sunbeam Incandescent Lamp Company filed a motion in the United States Circuit Court at Chicago last Tuesday to dissolve the restraining order granted to the General Electric Company some time ago, prohibiting the former company from manufacturing or selling incandescent lamps.

The attorneys on both sides of the case met in Judge Grosscup's court on Thursday last, and after a short discussion the attorneys representing the General Electric Company agreed to join the Sunbeam Lamp Company in a motion to modify the restraining order to the extent of allowing the latter company, by giving a bond, to manufacture their lamps, and in return the Sunbeam Company agreed to a hearing of the case in July.

After this agreement was made the counsel for the General Electric Company telephoned their action to the chief counsel in New York, and received word in reply that they would not agree to bind their company to the arrangement made by the local counsel.

Not having filed an answer, Counselor Payne withdrew the motion. The original motion to dissolve the restraining order is, therefore, now before the court and will be heard in the course of the next ten days.

The electric light has been introduced into a new flour mill near to the supposed site of Calvary and close to the Damascus gate at Jerusalem.

Legal Notes.

The suit of James W. Bennett against the Erie Telegraph and Telephone syndicate, which has been before the courts in Massachusetts since 1886, has been finally settled. At a conference held between Mr. Bennett and a representative of the syndicate it was agreed to enter judgment for neither party. This was brought about by the agreement on the part of the syndicate that no claim would be made for damages on account of keeping the property of defendants tied up for nearly seven years. The case has cost both parties between $20,000 and $25,000. The amount obtained in the three suits had they been decided for plaintiff would, it is said, have amounted to no more than $35,000 or $40,000.

The Highlands Electric Light Company was about to put up wires in Eleventh avenue in Highlands, Col., when the Colorado Telephone Company applied for an injunction restraining the light company from using the avenue on the ground that its wires, which run along the thoroughfare, would be injured by the induction of the current from the electric light wires if placed where it was intended. The court's order was that the light company should construct its wires high enough above the telephone wires to avoid the induction.

The opinion of the court restraining the Norristown Passenger Railway Company from increasing the capital stock or using any shares of stock beyond one thousand (its original capital) by virtue of any resolution of stockholders passed on the 5th day of April, 1893, is based wholly upon the ground that a railway company is a private corporation, which, under Article XVI, Section 7, of the Constitution of Pennsylvania, "Cannot increase its stock or indebtedness without the consent of the persons holding the larger amount in value of the stock first obtained, at a meeting to be held after sixty days' notice, given in pursuance of law." Only eight days' notice of the special meeting of April 5th had been given, and therefore the court holds that the stock authorized at that meeting cannot be legally issued.

The Schuyler Electric Light Company, at present furnishing light for Hagerstown, Md., has filed a bill in court asking an injunction restraining the street commissioners from closing the new contract for lighting with the street railway projectors. The grounds for the suit are that the commissioners were going out of their jurisdiction in allowing the guarantee of a railway to influence their decision in the light contract award.

Chancellor McGill has granted an order upon the officers of the Franklin Electric Light Company of Cape May, N. J., to show cause why a receiver should not be appointed. The writ was made returnable at Trenton Tuesday of this week. The company's indebtedness is reported at about $14,000, divided as follows: Ed. D. Mullen, $3,700; J. Henry Edmunds, bond, with accrued interest, $9,000, and outstanding floating debts making up the balance. The officers of the company, as originally constituted, are: President, F. J. Melvin; secretary and treasurer, J. M. E. Hildreth; superintendent, J. E. Taylor; directors, W. B. Miller, Lafayette Miller and the officers of the company.

Marine Electric Lighting.

Electric Plant, an English electrical journal, has just issued an elaborately illustrated special number devoted to marine electric lighting and other applications of electricity to novel purposes. The descriptions relate to the English, American and French navies, passenger ships and pleasure yachts, and comprise a most interesting resumé of the numerous ways in which electricity is now utilized on shipboard.

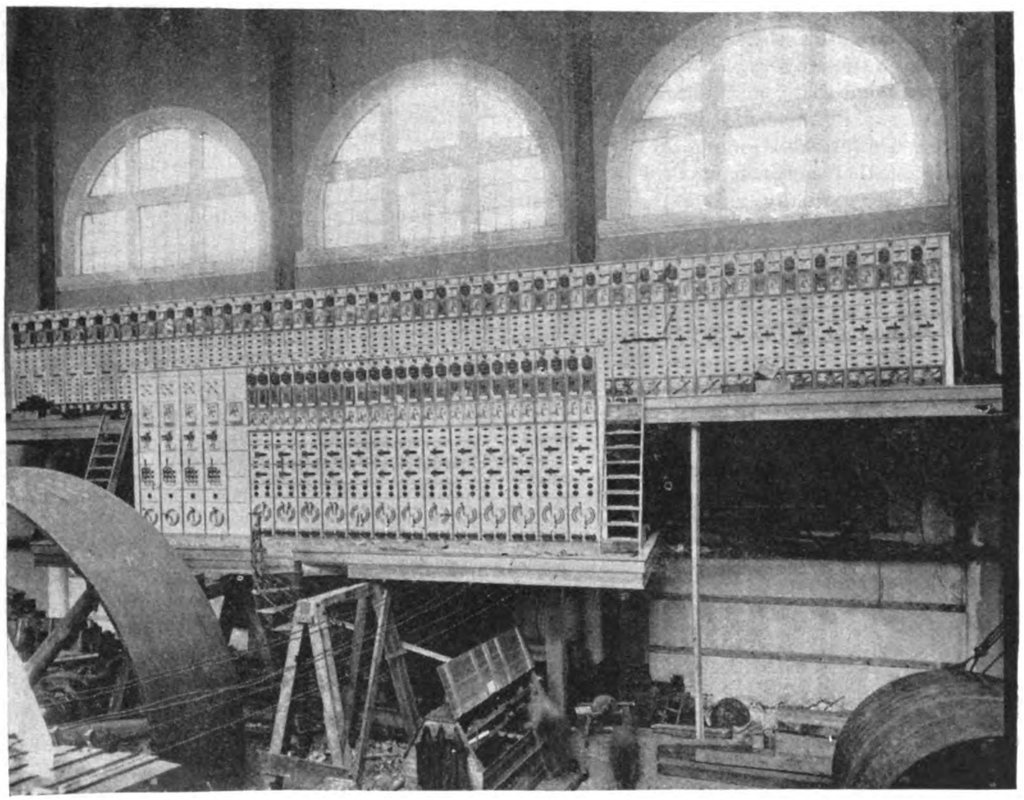
World's Fair—Department of Electricity.

In no week during the preparation of the Columbian Exposition has a greater progress been made in arranging for exhibits than during the past week.

Additional men have been put to work, and although the exhibits were not all in place on May 1st, enough laborers have been engaged to have the Exposition ready for visitors during the second week.

In the Electricity Building the General Electric Company have a portion of their exhibit in place. The generators exhibited consist of twenty-four dynamos which range in size from 300 kilowatts to ½ kilowatt machine. The Western Electric Company have a large force of men engaged in erecting their exhibit, which is located in the southeast corner of the building.

Unless some new arrangement can be made, the large search-light, about which so much has been written, will not be displayed at the fair. Director of Works Burnham decided last week that the roof of the Manufacturing and Liberal Arts Building would not sustain the weight of the apparatus necessary to operate the light. It is hoped that some arrangement will be made to build a special tower on which to mount the 20,000,000 candle power lamp.



THE MAIN SWITCHBOARD AT THE WORLD'S FAIR.

The Westinghouse switchboard, shown in the illustration, has at last been completed, and wiremen are now engaged in connecting the various circuits to their respective positions on the board. The switchboard is undoubtedly one of the finest ever built, and at the same time the largest in this country. The board is made of white marble, finely polished, and is elevated about 20 feet above the floor of the Machinery Hall. The lower part of the switchboard is 32 feet long and 11 feet high, and contains the switches for connecting the dynamos. The upper portion is 70 feet long and 10 feet high, and is used as the distributing board.

Sleepy Eye is the name of a Minnesota town which has just made a contract with the Thomson-Houston Company of St Paul for an electric light plant to cost $10,000. When they get new light, the citizens may be able to find a livelier name for their town.

BOOK NOTICES.

ALTERNATING CURRENTS OF ELECTRICITY. By GISBERT KAPP, C. E., 1893. THE W. J. JOHNSTON COMPANY, LTD., New York. Price $1.00.

The principles of alternating currents are developed in this book in a simple manner that can be followed by any reader, and the various applications are sketched in a broad and instructive way that clears away the many mysteries with which they were supposed to be surrounded. The few mathematical formulæ in the book are confined to appendixes.

The first four chapters are devoted to explaining alternating currents and their measurements, and the three succeeding ones are on the principles and design of alternating current machines and transformers. Chapter VIII is on alternating current central stations, and Chapter IX is on the parallel coupling of alternators.

The remaining chapters treat of various forms of alternating motors, especial attention being paid to the explanation and discussion of multiphase motors. This subject is treated so clearly that the reader is enabled to form as clear an idea of these new forms of motors as of the simpler continuous current machines.

The treatment throughout is thoroughly practical, and the data and discussion on the design and construction of apparatus will be found useful to the electrician and designer.

ENGINE ROOM CHAT. By ROBERT GRIMSHAW, M. E. PRACTICAL PUBLISHING COMPANY, 21 Park Row, New York. Price $1.00.

This book consists of a collection of paragraphs concerning the work of engineers and firemen of steam plants, written in a popular style, and contains some good advice as to the duties of this class of workers.

A number of these sketches have appeared in the *Engineering Magazine*, *Dixie* and elsewhere, and others appear for the first time in the present volume.

The book will be mailed, post paid, by the publishers on receipt of price.

The World's Fair Opened.

President Cleveland Presses the Button which Starts the Wheels in Machinery Hall.

Over a Hundred Thousand People Present.

Four Weeks More of Work to Put the Exhibits in Perfect Order.

While the exhibits at the World's Fair are by no means in perfect readiness, the formal ceremonies of the opening took place according to the original programme on Monday last, in the presence of upwards of one hundred thousand people.

After the playing of the "Columbian March," prayer was offered by the Rev. W. N. Milburn, the blind Chaplain of the United States Senate.

Following this came the reading of W. A. Croffut's poem, "The Prophecy," by Miss Jessie Couthoui, and the address of Director-General Davis.

President Cleveland then spoke as follows:

"I am here to join my fellow-citizens in the congratulations which befit this occasion. Surrounded by the stupendous results of American enterprise and activity, and in view of magnificent evidences of American skill and intelligence we need not fear that these congratulations will be exaggerated. We stand to-day in the presence of the oldest nations of the world, point to the great achievements we here exhibit, asking no allowance on the score of youth. The enthusiasm with which we contemplate our work intensifies the warmth of the greeting we extend to those who have come from foreign lands to illustrate with us the growth and progress of human endeavor in the direction of a higher civilization.

"We who believe that popular education and the stimulation of the best impulses of our citizens lead the way to a realization of the National destiny which our faith promises, gladly welcome the opportunity here afforded us to see the results accomplished by efforts which have been exerted longer than ours in the field of man's improvement, while in appreciative return we exhibit the unparalleled advancement and wonderful accomplishments of a young nation, and present the triumphs of a vigorous, self-reliant and independent people.

"We have built these splendid edifices, but we have also built the magnificent fabric of a popular Government whose grand proportions are seen throughout the world. We have made and here gathered together objects of use and beauty, the products of American skill and invention; we have also made men who rule themselves.

"It is an exalted mission in which we and our guests from other lands are engaged as we co-operate in the inauguration of an enterprise devoted to human enlightenment, and in the undertaking we here enter upon we exemplify in the noblest sense the brotherhood of nations. Let us hold fast to the meaning that underlies this ceremony, and let us not lose the impressiveness of this moment. As by a touch the machinery that gives life to this vast Exposition is now set in motion, so at the same instant let our hopes and aspirations awaken forces which in all time to come shall influence the welfare, the dignity and the freedom of mankind."

When the President had finished his speech he stepped over to a table draped with the American flag.

Mr. Cleveland struck the electric button vigorously, and the circuit to the Allis engine and the Worthington pump was at once thrown on. There came a roar of revolving wheels from Machinery Hall, the fountains in the lagoon burst forth into active life, the veil which covered the immense bronze figure of Liberty was thrown aside, and the screaming of hundreds of steam whistles filled the air.

The great orchestra took up the grand strains of the "Hallelujah Chorus" of Handel, and the World's Columbian Exposition was formally opened.

Some Applications of Electricity to Chemistry.*

Most of the applications of electricity to chemistry depend on the electrical decomposition of saline solutions, or electrolytes. A glance at the work of the chemist shows that a very large proportion of his labors consists in oxidizing or reducing the various substances with which he deals. Sometimes he is making changes or substitutions, but his chief work is oxidizing and reducing. Here, then, we have at once the reason why electricity is becoming so important. Consider for a moment the advantage of the electrical over the chemical method. Take the case of water already mentioned. To reduce it to hydrogen it would have to be, let us say, heated in contact with iron, carbon, or something which has enough affinity for oxygen to abstract it from the water. In this case, the hydrogen is set free, but the oxygen is not; it is combined with another body. Again, to oxidize the chloride some such treatment as that with manganese dioxide and sulphuric acid is necessary. By electrolysis, however, the oxygen and hydrogen, or the copper and chlorine, are produced direct without any complications and without introducing foreign substances. When it is remembered that many of the ores from which the metals are obtained are oxides, and that the smelting of these consists of reduction only, and is carried out in a manner which gives impure metals, and that the remaining ores are mostly sulphides, which are roasted into oxides, and then reduced, it will be realized that electricity has a magnificent future in metallurgy. This is not by any means all. The important alkali industry consists of splitting up common salt into caustic soda and chlorine, and the process of manufacture, as at present carried on, is a bewildering maze of oxidation, reduction and substitution. In making alkali and bleaching powder by the Leblanc-Weldon processes, beginning with salt and pyrites and ending with caustic and chlorine, there are, taking it favorably, four oxidations, one reduction, and three substitution processes. By electrolysis, salt is decomposed into caustic soda and chlorine at one operation without the aid of any other chemicals, and without any waste, loss, or by-product. Direct electrolysis of solutions of salts is by no means the only process available; fused salts can be electrolized, and aluminium is reduced extensively from its salts by this method. It is probable that sodium and potassium will soon be produced from their fused salts in the same way.

Electro-deposition is now largely practised in copper refining. Crude copper is cast into anodes and placed in vats of sulphate of copper with thin sheet copper cathodes. The copper is dissolved off and deposited on the thin cathode plates. The silver and gold fall to the bottom, with various impurities, such as antimony and arsenic. The silver and gold are thus completely separated, and the crude copper is changed for the much more valuable pure product. Lead would be treated much in the same way if it were not that it is apt to deposit in a loose spongy form, instead of in a coherent mass. Electrical processes are also coming into use by which many of the ores are merely roasted to convert them into oxide, and then dissolved in acid, the solution being electrolized to yield the metal in a state of almost perfect purity.

One of the most important applications of electricity will be in the manufacture of soda and bleaching powder direct from salt. If a solution of salt is electrolized, caustic soda is produced at the cathode and chlorine is given off at the anode. The chief difficulty is to find a good material for the anodes. Carbon is the only material available. It is attacked to some extent, not by chlorine, but by oxygen; but electrolytic soda has now reached a stage in which this last difficulty may be said to be overcome by using a form of carbon which is so cheap that its corrosion does not much matter. At Snodland there is a model caustic plant at work which has been making soda and bleaching powder by the ton for some time. If the caustic is allowed to mix with the rest of the liquid, chlorine is no longer given off, but the salt is changed to hypochlorite of soda. This may be used for bleaching. If the operation is now carried on at a higher temperature, chlorate is formed. Chlorate of potassium is now manufactured on a large scale from the chloride in this way.

One of the most complicated branches of the study of chemistry is the formation of dyestuffs. Oxidation and reduction can frequently be carried out by electrolysis without introducing special oxidizing and reducing agents. Here, then, is a wide field for scientific research. Dr. Goppelsroeder has done a great deal of work on the subject, but it is well worthy of further attention. Whether such a process is valuable commercially is a matter of doubt, but it provides the chemist with a new method of investigation, and may lead to important discoveries in this branch of organic chemistry.

Electricity also derives benefits from chemistry. Faraday discovered that the quantity of metal deposited was strictly proportional to the quantity of electricity passed through the solution. This has provided electricians with a very exact method of measuring quantities of electricity. Lord Rayleigh has made very careful determinations of the exact weight of silver deposited by a unit quantity of electricity, and this measurement now serves as the practical standard for the measurement of electricity, and hence of electric currents.

An Electric Yacht Libelled.

The yacht Electron was recently libelled in the United States District Court by the Electro-Dynamic Company to recover a balance of $2,000 due for furnishing the yacht with 250 additional storage batteries and other material in 1891. The batteries were added for the purpose of increasing the motive power and giving the yacht more speed. It was found that the additional cells did not increase the speed to the desired limit; and the owner not only refused to pay the $2,000 demanded but entered a cross-suit for the recovery of $2,000 already paid. Judge Addison Brown, before whom the case was brought, decided in favor of the electric company on the ground "that the whole subject was in the nature of an experiment which, whatever may have been the hope or expression of confidence as to the result in increased speed, no warranty or guarantee was assumed by the libellant."

The defence having alleged that the batteries were an infringement of the Brush electric patents, the Judge ordered the libellant within thirty days to procure from the Brush Electric Company a license to enable the yacht to continue the use of the batteries.

Current Items.

The ideal method of using electricity in manufacturing, in the view of Alexander Siemens, is to supply an electric motor to each machine tool. This reduces the strengthening necessary for floors, and dispenses with shafting, counter-shafting, bands and pulleys. Lord Kelvin has made calculations to show whether power can better be transmitted by shafting and belting or by electricity. His results prove that electric transmission supplied to the machines at least 70 per cent. of the indicated horse power, while with the shafting not more than 60 to 63 per cent. is made available.

Russian engineer officers have been experimenting with an electric hand-lamp of Russian invention. It seems to be well adapted to the inspection of mines and trenches at night. The lamp, or lantern, is in the form of a tube two and a half feet long, the interior being made of tin. Tiny cells, forming a battery, are placed in this tube and connected in a special manner. The light is enclosed in six plates of glass at the top of the tube, and the brilliancy is regulated by a screw at the lower end.

Nelson Perin, president of the City and Suburban Railway Company, has been presented by the residents of Towsontown Md., with a silver pitcher bearing the following explanatory inscription: "Presented to Nelson Perin, president of the City and Suburban Railway Company, by the citizens of Towsontown, Baltimore County, Maryland, as a testimonial of their appreciation of his enterprise, displayed in completing the electric railway from Baltimore to their town."

H. Sellers McKee, the electric railway magnate, says it will not be long before an electric line will be built between New York and Philadelphia, and the run between the two cities made in one hour with one stop only (at Trenton). The cars and rails will be of a special design and very heavy in construction, with the cars built so as to bring the center of gravity near the track level. The engines and motors will be of special pattern and extra power. "All these difficulties," adds Mr. McKee, "I am confident the ingenuity of George Westinghouse will surmount."

India now boasts the finest land telegraph service in the world. Recently duplex messages were transmitted without relays a distance of 2,100 miles over a line extending from Calcutta to Madras. The wire employed was of copper, and the feat was rendered possible by the employment of an apparatus introduced by a member of the Indian Telegraph Staff.

After a debate extending over three hours, the Senate of the Connecticut Legislature passed the General Electric Street Railway bill by a vote of 17 to 5. It becomes imperative that a majority of all directors of all street railways must reside in the State. This will place control of all electric roads and street railways in the hands of local authorities, subject to the restrictions made by the railway commissioners regarding carrying freight and paralleling steam railroads.

Last Monday the Boston *Journal* appeared as a 60-page sheet in commemoration of its having completed sixty years existence. Reading notices and cuts of the works of many of the leading industries of Boston and New England filled page after page, the various electrical firms and corporations securing unwonted space. The electrical industry was characterized as being the leading industry of Boston, and the various concerns must have been gratified at reading the complimentary notices published about them. It was a great piece of journalism, and the electrical features of it were among the most startling and attractive.

---

* Abstract from *Industries* of lecture at the Royal Institution, delivered by Mr. James Swinburne.

Personal.

The engagement of Mr. L. E. Whicher, of Boston, to Miss M. Brausen, of Cincinnati, is announced.

Mr. Whicher is a director of the Beacon Vacuum Pump and Electrical Company, and has been its treasurer since the formation of the company. He is also a member of the firm of T. A. Whicher & Company, one of the oldest and largest shoe manufacturing concerns in the world.

Miss Brausen is a most estimable as well as charming young lady.

The engaged couple have the best wishes of a host of friends both in Boston and Cincinnati.

General News.

What is Going on in the Electrical World.

Donaldsonville, La.—The establishment of an electric light plant is being discussed here.

Seattle, Wash.—A proposition for the purchase of a $100,000 electric light plant is to be submitted to a vote of the citizens.

Rhinebeck, N. Y.—The contract for the construction of the electric road between Rhinebeck and Rhinecliff will soon be opened for bids.

Rome, Ga.—The formal transfer of the Rome Gas Light Company's electric property was made a few days ago to the Rome Electric Light Company.

Salisbury, Md.—The plant of the Electric Light and Power Company was destroyed by fire on the 22d ult. The company's loss was $15,000.

Providence, R. I.—The ordinance permitting the Union Railroad Company to operate cars by the electric trolley system has been approved by the city council.

Albany, N. Y.—The State Board of Railroad Commissioners has approved the use of electric motor power on the New Paltz and Highlands Street Surface Railroad.

Gettysburg, Pa.—The electric railway that is to form something like a belt road over the battle lines of the famous field will be ready for operation by the 1st of July.

Oshkosh, Wis.—A. F. Ferdinand has asked permission of the council to place poles, wires, and other requisite things for conducting a new telephone system in this city.

Tampa, Fla.—The Tampa Street Railway and Power Company will have electric cars on its line in a few weeks. The Consumers' Company is already running its cars by electricity.

Little Rock, Ark.—The City Electric Street Railway has been placed in the hands of a receiver on application by the St. Louis Trust Company for default of April interest on $300,000 bonds.

Middletown, Md.—Some New York parties have been looking over the route of the projected electric railway between Frederick and Middletown and were favorably impressed with the scheme.

Sheridan Post, Col.—Subscriptions for stock in the proposed electric light company are filling up satisfactorily. The company will be capitalized for $30,000, and the plant is estimated to cost $15,000.

Cincinnati, Ohio.—The new electric light building which was in course of erection here collapsed on the morning of the 24th ult., killing some of the workmen engaged on it and wounding several others.

Fargo, N. D.—The new electric light and power company have purchased lots, and will immediately put up a power house. The plan provides for 450 horse power, to run machinery and street railways.

Conshohocken, Pa.—The directors of the Montgomery Passenger Railway have decided to begin immediately the construction of the trolley line from the Bridgeport terminus to the borough line of West Conshohocken.

Duluth, Minn.—City Engineer Cooper has furnished the common council an estimate for an electric light plant to be owned by the city. It is designed to supply an arc light circuit and its cost is estimated at $100,000.

Dallas, Tex.—Ft. Worth and Dallas are to be connected by an electric railway in which New York and Philadelphia capitalists will have a leading interest. Spencer M. Janney, of Philadelphia, is president of the new company.

Elizabeth, N. J.—The Elizabeth and Plainfield Electric Light Company has made an application to the Street and Law Committee of the city council for a franchise to construct an electrical railway from Elizabeth to Plainfield.

Missoula, Mont.—The Electric Light Works Company expect to have their new dam on the Missoula River, a short distance east of this place, completed by the middle of June, and will move their entire plant to that point.

Buffalo, N. Y.—The city chemist, Dr. Herbert M. Hill, has been testing the arc lights furnished to the city by the General Electric Company, and reports that many of them give a feeble light, far below the requirements of the contract.

Syracuse, N. Y.—The People's Railway Company has secured the necessary signatures for the change from animal to electrical power in South Salina street, and the work of obtaining signatures in North Salina street is going on rapidly.

Freeport, Ill.—Congressman Haines has been granted a fifty year franchise for an electric street railway in this place and will shortly begin the work. He will also create a pleasure resort in the suburbs to which the line will be extended.

Dover, Del.—The Senate passed the House bill authorizing the town of Smyrna to borrow $25,000 for building sewers and erecting an electric light plant. It provides that an election shall be held first, to ascertain the wishes of the people.

Charleston, S. C.—The Enterprise Street Railroad has become the property of the Great Western Manufacturing Company of Chicago and Duluth, who will convert it into an electric line if a franchise can be obtained from the city council.

Gloversville, N. Y.—The railroad trouble in Gloversville has been settled. The common council has granted a franchise to the Cayadutta Company, which enables them to connect with the Johnston and Gloversville Railroad and the Belt line.

Cleveland, Ohio.—The stockholders of the Cleveland Electric Railway Company have formally ratified the consolidation of the East Cleveland, Broadway and Brooklyn companies. Henry A. Everett has been elected president of the new company.

West Chester, Pa.—The Lancaster and Philadelphia Electric Traction Company has now secured the right of way from Coatesville and Malvern, and the prospects are that Atglen, Parkesburg and Downingtown will grant rights within a short time.

Shelbyville, Ind.—The common council advertises for proposals for lighting the streets of this city for a term of five years from July 1, 1894. Proposals will be received until September 1, and particulars may be obtained by addressing C. Ahele, chairman of committee.

Vicksburg, Miss.—The consolidation of the interests of the Vicksburg Electric Street Railroad Company and the Hill City Electric Light Company is announced. The railway has some track laid, but none in operation at this time. The electric company is lighting the city.

Boston.—The House has passed an act giving the Storage Battery Company the right to run its cars over the tracks of the West End Railway.—The electric welding process of Prof. Thomson has been applied in a practical manner and successfully to street car rails in Johnstown, Pa.

Huntington, L. I., N. Y.—Among those interested in the new electric company forming here are Dr. Walter Lindsay, Rev. Samuel T. Carter, William H. Stoyle, Charles B. Scudder, Rev. Francis C. Hill, J. Abner Smith, Ansel B. Gildersleeve, Philip Pearsall and Thomas Aitkin.

Los Angeles, Cal.—The city council has adopted an ordinance providing for the sale to the highest bidder of a franchise for a street railway, and the sale will take place on May 22. The franchise runs for thirty years and provides for the construction of an electric railway along certain streets in the city.

Baltimore, Md.—The *Herald*, in an editorial, cites several instances of the success of electrical suburban railway lines carrying freight as well as passengers, and says the level Eastern Shore of Maryland would be an ideal place for such transit. Electric roads may yet solve the transportation question for that garden spot of the State.

New York.—The stockholders of the Anglo-American Electric Light Manufacturing Company, which formerly did business at Kensington, met at the Metropolitan Hotel on Broadway, New York, recently, and moved to dissolve the corporation and to discontinue business. Frederick R. Lee, secretary of the company, is to settle up affairs and divide whatever may be left among the stockholders.

Brooklyn, N. Y.—A new electric road will be built in the Twenty-sixth Ward. The proposed line will be from the Cleveland street station of the Union Elevated Railroad through to Linwood street, down to the Mill road to Jamaica Bay. Among those interested are J. Grattan McMahon, Nathan Kaplan, Alexander Foreman, Dr. George C. Jeffrey and Fred. C. Dexter.

Toronto, Can.—The Automatic Telephone and Electric Company of Canada, incorporated by special Act of the Dominion of Canada, March, 1893, and assented to the 1st of April, 1893, to transact a telephone and electrical supply and manufacturing and operating business throughout the Dominion of Canada, intend increasing their capital stock to $250,000, and offer the stock to the public.

Hartford, Conn.—The Senate has at length passed the Electric Railway bill, after agreeing to the amendment requiring a majority of all directors of street railway companies to be residents of the State. The bill places control of all electric roads and street railways in the hands of local authorities subject to the restrictions made by the railway commissioners regarding carrying freight and paralleling steam railroads.

Concord, N. H.—The Concord Land and Water Power Company has purchased from the Concord Gaslight Company the gaslight company's power house on Bridge street, with all its electrical appliances, poles, lines and supplies for electrical business in Concord. The Land and Water Power Company has also purchased the exclusive right to use the water power at Garvin's Falls for the generation of electricity to be used in any form or for any purpose in Concord and north of Concord for a term of fifty years.

Altoona, Pa.—The Logan Valley Electric Railway Company has absorbed the Altoona City Passenger Railway, having purchased a majority of the shares of stock. The following were elected officers of the reorganized company: President, John Lloyd; secretary and treasurer, C.A. Bunch; directors, John Lloyd, M. H. Canan, M. H. Mackey, J. C. Hughes, A. C. Shand and Cornelius Campbell, of the Altoona and Logan Valley Company, and James Lowther, A. J. Anderson and D. K. Ramey, of the Altoona City Passenger Railway Company.

Indianapolis, Ind.—The syndicate which, through its attorney, ex-Judge Byron K. Elliott, has made such a liberal bid upon the franchise for the street-railroad privileges, is believed to be the strongest combination financially that has ever dealt with any Indianapolis enterprise. Messrs. Dieterich and Benedict are said to be the leaders in the combination, which is composed of over twenty members. The bid will probably be accepted by the council, although the Citizens' Company maintains that its franchise is a perpetual right.

Toledo, Ohio.—The electric railway enterprise which the Put-in-Bay and Southwestern Railway Company has in view comprehends a line from Findlay to Fostoria, thence to Tiffin and to Fort Seneca, and from there to Fremont and Port Clinton. At this place it is proposed to divide the system, running a branch to Catawba Island and Ottawa City. From there a ferry will be run to Put-in-Bay. The other branch is projected to Lakeside, on Lake Erie. Still another branch of the system will run from Tiffin to Upper Sandusky. As projected, the road will be about 150 miles in length. The main line will be part of the local system in the towns touched.

St. Louis, Mo.—The Missouri Pan Electric Telephone Company have elected the following officers: President, Samuel Kennard; vice-president, Dr. K. Morgner; secretary and treasurer, F. W. Mott; board of directors, John H. Terry, Chas. H. Peck, K. Morgner, John H. Keiser, Sam Kennard, Epham Catlin, S. R. Francis, A. Moll, Dr. J. O'F. Delaney, James Black, Fred W. Mott, P. Nicholson and S. F. Ramsey. The company intend putting up private wires to commence with and then introducing an exchange system. They have been advised by the attorney of the National Company to go ahead and give no attention to intimidation by the Bell Company.

Portland, Ore.—What promises to be one of the most elaborate water-power plants in the world is now in process of erection at Portland. It will be operated by the Portland General Electric Company, which proposes to utilize the falls at Portland not only to make electric lights, but also to run a number of electric street railway lines and to supply electric power to the citizens of Portland. Ten thousand horse power is to be generated in blocks ranging from 600 horse power down. Twenty-two turbines are to be put in at once—two 48-inch, ten 42 inch and ten 60-inch vertical cylinder gate wheels set in iron flumes and feeds.—The poles for overhead wires on the Portland and Vancouver Railway have been planted as far as Woodlawn. The whole line, it is thought, will be completed and in operation in sixty days.

Boston Notes.

The Legislative Committee on Railways after considering the evidence put in by the Storage-Battery Railway Company, of Cambridge, in support of its petition for authority to run cars over the tracks of the West End Railroad, reported to the House leave for the petitioners to withdraw. The House, however, substituted the bill of the petitioners, which bill will be discussed in the House at an early date. Meantime the promoters are maturing their plans, being sanguine that their reasonable petitions will finally be granted.

The installation of lighting plants on the four Nantasket Beach steamboats has just been completed by the New England Weston Electric Light Company, and the work has been inspected by a representative of the General Electric Company, who failed to secure the contract, and he candidly expressed his opinion that it was the best piece of work he had ever seen done. An admission like that from an unsuccessful competitor should amount to something.

There is a decidedly strong public opinion growing up in Lynn in favor of all overhead wires being put underground. Professor Elihu Thomson has been consulted and he is reported as being favorable to such a change. He considers the plan both feasible and practicable, and considers that the removal of personal danger together with the increased efficiency of the fire department would justify all the labor and expense that might be involved.

So well known and respected in Lynn are Prof. Elihu Thomson and E. W. Rice, Jr., the latter being superintendent of the General Electric Company's factories, that two steamboats have been named after these gentlemen.

One of the chief attractions at the Mechanics' and Merchants' Exhibition now being held in this city is the serving of meals every course in which is cooked by electricity. Madame Lemcke is the chef and her culinary operations with the new medium engross every visitor's attention.

The aldermen of the city of Brockton have decided that in future passengers by the electric street cars shall ride to any part and all parts of the system for a uniform fare of five cents. The new rule will apply to the East Side and Whitman branches, two out-of-town sections of the road. In granting franchises for the construction of roads in Stoughton and Bridgewater the aldermen imposed a like condition.

Some very successful experiments have just been made in Lynn with the Genette patent air brake for street cars. This apparatus may supersede the old style of hand power for stopping cars. The air is compressed by the revolution of the wheels and operated in nearly the same manner as on steam cars. It was proven that a car running at seven miles an hour can be stopped within a distance of its own length. The Lynn and Boston road is to equip a number of its electric cars, and if all that is claimed for this invention is sustained, all its cars will be so equipped.

To obviate the difficulty and danger arising from the leakage of current from the return circuits on the West End Railroad much larger wires are being laid in various parts of the city. The new wire is about five-eighths inch diameter tinned copper.

A new incandescent lamp is being perfected in the John Hancock Building which the inventor, Mr. D. C. Voss, claims is something entirely different from any other lamp ever made. Its special feature is the way in which the leading-in wires are secured. Unlike the Edison lamp these wires are first imbedded in a plastic substance which is then secured in the neck of the lamp bulb. Experiments have been made at a lamp factory in Brockton which have proven highly successful, and lamps are now burning that have been in service several weeks and show no falling off in efficiency. It gives a clear white light, the heat evolved being scarcely perceptible. Parties are now negotiating for the purchase of the patents. Much interest is being taken in this candidate for public favor.

The Van Choate Electric Light and Storage Battery Company has removed its chief offices to Portland, Me. The directors report satisfactory progress being made in the closing up of certain transactions that will enable the company to begin actual business ere long. This company does not appear to have met with the recognition in Boston from capitalists that its promoters anticipated.

The first annual meeting of the Van Choate Electric Car and Light Company was held in Portland, Me., Wednesday, April 19, at which meeting a complete change was made in the board of directors. The seven new members consist almost entirely of Boston men, while the previous board was composed mainly of New Yorkers. The new management will be entirely in harmony with Mr. Van Choate.

Mr. Henry Kaliske, the genial and enterprising manager of the Beacon Vaccum Pump and Electrical Company, Boston, goes on a fishing trip next week. As he is notorious for his adeptness in handling the rod, flinging the fly and all the other minutiæ of Isaak Walton's favorite pastime, Mr. Kaliske's innumerable friends regard it as a foregone conclusion that he will return from his trip with a creel full of finny beauties either as big as a tarpon or as diminutive as the aristocratic whitebait.

Chicago Notes.

Mr. J. H. Dean, of the West Side Electric Company of St. Paul, was a visitor in the city last week.

Mr. J. G. Nolan, formerly with the Illinois Lamp Company, has been appointed electric light inspector by the recently elected Mayor.

Mr. F. S. Palmer, manager of the Electric Heat Alarm Company, of Boston, arrived in Chicago this week. Mr. Palmer will make a very interesting display of his apparatus at the World's Fair.

T. A. Pamperin, President of the Electric Manufacturing Company of Oconto, with his attorney, was an interested listener to the proceedings of the incandescent lamp case in progress before Judge Grosscup.

Riehle Bros.' Fair Exhibit.

Riehle Bros. Testing Machine Company, Philadelphia, are installing a very extensive and interesting exhibit at the World's Columbian Exposition, Machinery Building, Column 0 25. Among other articles they will exhibit: 300,000 lb. Vertical Screw Power Testing Machine with Patented Electric Automatic Screw Beam, Plate 178; 200,000 lb. Horizontal Car Coupler Testing Machine, arranged for links, pins and brake beams, Plate 22; 200,000 lb Vertical Screw Power Testing Machine, Plate 154; 100,000 lb. Vertical Screw Power Testing Machine with Electric Automatic Beam, Plate 34; 80,000 lb. Spring Testing Machine, Plate 210; 20,000 lb. Vertical Screw Power Testing Machine with Vernier Poise, Plate 153; 20,000 lb. Horizontal Hand Tester, Plate 10; 5,000 lb. Transverse Testing Machine with Indicator, Plate 13; 3,000 lb. Transverse Testing Machine with Indicator, Plate 26; 5,000 lb. Torsional Testing Machine, Plate 159; 1,000 lb. Cement Testing Machine, with worm gear and rubber grips [the style the United States Government uses], Plate 14; also, Cloth and Twine Testing Machines

In addition to this, they also show their latest improved Patented Marble Molding and Countersinking Machine, and other articles of interest too numerous to note here in detail.

They applied for more space than they obtained, and were obliged to erect a platform on which to place some of their smaller Testing Machines.

This exhibit is in charge of Mr. J. R. Matlack, Jr., who is well known to the professors of the leading universities in the United States, also the officials of the railroads and the larger iron and steel works throughout the country.

At the Government Building in the Government Exhibit, in charge of Capt. A. H. Russell, will be found a Riehle 200,000 lb. Vertical Screw Power Testing Machine; and in the Quartermaster's Department in the Government Building, a 200 lb. Cloth Testing Machine. These were loaned by the Riehle Bros. Testing Machine Company to add to the Government Exhibit.

An exhibit of the Riehle-Roble Patented Frictionless Ball-Bearing Screw Jacks will be found in the Government Exhibit, as well as in the space of the Riehle Bros. Testing Machine Company.

The Columbia Incandescent Lamp Company.

The following announcement is sent out by the winners in the recent lamp suit at St. Louis:

The bond given by us affords protection to buyers of Columbia lamps against claims for infringement or royalties by the General Electric Company, and under present conditions, by reason of the above, this is the only company other than the General Electric Company, offering absolute protection to users of incandescent lamps.

In defeating the Edison Company we have not alone been benefited, but every purchaser of electrical apparatus, lamps and supplies has participated in our success, and we therefore feel justified in expressing the hope and belief that we shall have the support of all buyers of incandescent lamps, by receiving their orders on equal terms offered by the General Electric Company.

During our past four months' fight with the Edison Company, our expenses legal and otherwise have been extremely heavy, and should the case go to a final hearing, the cost will reach a large additional sum; we have therefore felt obliged to adopt the following schedule of prices for Columbia lamps, which prices are identical with those now being made by the General Electric Company; although, as you will note, we depart from their rule by making no extra charge for lamps in other than Edison base:

16	C. P., 500 or upwards,	$.50	net.
16	" less quantity,	.55	"
32	"	.75	"
50	"	1.35	"

Yours truly,
THE COLUMBIA INCANDESCENT LAMP CO.

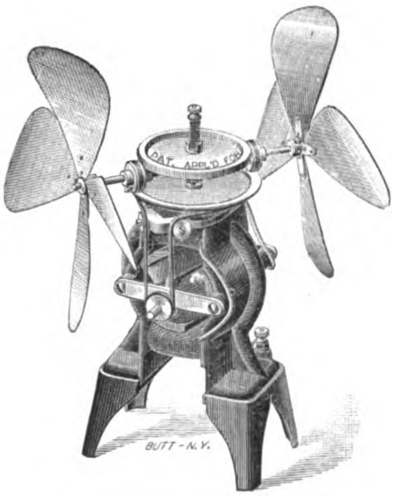
Electric Gas Lighting Company.

The tenth annual catalogue and price list of the Electric Gas Lighting Company of Boston has just been issued, and is the most complete and useful one which this company has yet published.

The list of goods embraced in this number demonstrates the growing extent of this company's business, which now includes all classes of domestic electric appliances, and which has recently necessitated a considerable extension of its manufacturing facilities.

The New De Mott Fan Motor.

The following cut illustrates a new fan motor just introduced by the De Mott Motor Company which is unique in a number of points of its construction and is designed to distribute the currents of air set up by the fans in all parts of the room in which it operates. To this effect the two fans shown in the cut are set on a horizontal shaft which has two distinct movements, one being a simple revolution about its axis and the other a horizontal revolution between the two discs shown.



THE NEW DEMOTT FAN MOTOR.

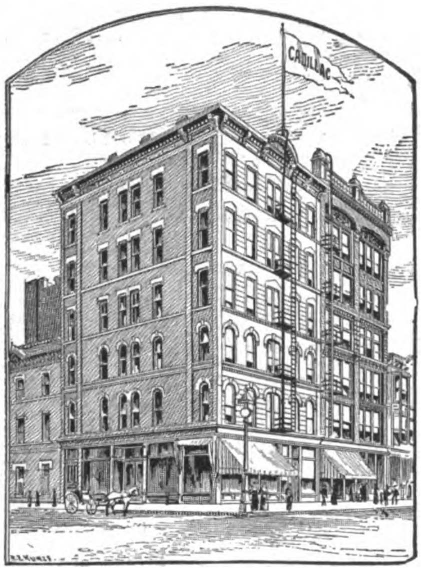
The upper disc consists of a gear which meshes with the pinions on the revolving shaft. In this way the effect of the fans is felt radiating in every direction from the motor.

In all previous attempts to produce this effect the motors themselves have been made to revolve about a vertical axis, and owing to the weight of the moving parts only a slow speed was found feasible. In the De Mott motor a much more mechanical arrangement is adopted, in which the inertia of the moving parts is reduced to a minimum, permitting a good speed to be attained, and reducing the power consumed proportionally.

World's Fair Hotel for Electrical People.

The Hotel Cadillac, shown in the illustration, has recently been leased and entirely refitted and refurnished with all the modern conveniences by Messrs. C. L. Pierce and Louis F. Allardt.

The proprietors have made special arrangements to entertain the electrical fraternity and their friends through the entire season of the Fair. All of the electrical journals are to be kept on file and daily bulletins of electrical information concerning the Fair and country in general will be posted for the benefit of its patrons. The hotel is pleasantly situated, being within two blocks of the lake. Ready access to the Fair grounds may be had by twelve direct routes, and it is also within walking distance of the business portion of the city. The hotel will be run on the European plan and will contain all the conveniences necessary to a modern building, including light, heat, baths and elevator service.



HOTEL CADILLAC, CHICAGO.

COMMERCIAL PARAGRAPHS.

The Pettingell-Andrews Company, Boston, has just issued its second annual catalogue, which is a remarkably handsome volume of 196 pages profusely illustrated with cuts of about every appliance, device and piece of apparatus used in the electrical business. The price of each article is given to facilitate business, and the book as a whole is so well arranged and complete in its details that no one in the business can afford to be without a copy. Incidentally it may be stated that the Pettingell-Andrews Company continues in the lead in New England as a supply house, and great as was the volume of business done last year the firm is doing 40 per cent. more business than a year ago.

The Shultz Belting Company, through its Boston house, has just sold 5,000 feet of leather belting of various widths to a European firm which purchases large bills of these belts almost every month. The Shultz factory in St. Louis is kept running almost night and day to keep up with its orders.

The W. S. Hill Electric Company, Boston, will have on the market in a few days a most unique fan motor equipment. By the aid of a crescent shaped brass rudder on which the current of air from the fan impinges the entire machine is kept revolving, so that every part of a room gets the benefit of the breeze in turn. It is by all odds the greatest novelty that has yet been introduced, and being high grade in every detail is bound to have a big sale.

The W.-W. Lightning Arrester, manufactured by the Ansonia Electric Company, formerly the Electrical Supply Company, is certainly built after the latest theoretical principles, and from all reports its success cannot be doubted. The Ansonia Company are also Western Agents for the Helios arc lamp, for both alternating and direct current lighting, and are in receipt of flattering reports from all directions as to the successful working of these lamps used on incandescent circuits.

The Ansonia Electric Company, formerly the Electrical Supply Company, report one of their largest weeks in the sale of the celebrated Shield Brand Moisture-Proof Line Wire.

The Ansonia Electric Company, formerly the Electrical Supply Company, will soon be in a better position than ever before to supply Wirt indicators and the standardized fuse links, as all testing, calibrating, etc., is now to be done in the new Wirt laboratory.

The Iona Manufacturing Company, Boston, the well-known makers of electrical supplies and specialties, of which Mr. N. Marshall is manager, have just removed their factory to very much larger and more commodious quarters, at 336 Congress street. By this change their capacity will be considerably more than doubled, and will enable them to take care of all orders hereafter with promptness.

The Ansonia Electric Company, formerly the Electrical Supply Company, recently received orders for some 1,800 ampere Wirt indicators.

A very handsome display of Wirt indicators will be made by the Ansonia Electric Company, formerly the Electrical Supply Company, in the Electricity Building at the Fair grounds.

INCORPORATIONS.

The Greenville, Ind., Electric Light Company has increased its capital stock from $25,000 to $50,000.

The American Electric Debenture Company, at Des Moines, Iowa. Capital stock, $500,000. Incorporators: David W. Evans, Charles E. Hunn and Eli S. Hunn, all of Des Moines. The officers are: President, L. R. Casey; vice-president, R. M. Newport secretary and treasurer, Frank F. Reed, and assistant secretary, Charles E. Hunn.

The Royal Arc Electric Company of U. S. A., to conduct a general electrical business at Plainfield, N. J. Capital stock, $1,000,000. Incorporators: Louis E. Howard and G. Harry Squires, of Plainfield; Frederick C. Marsh, of Elizabeth.

The Suffolk Gas Company of Islip, L. I., to manufacture and supply both gas and electricity. Capital, $200,000. Directors: B. I. H. Trask, I. L. Egbert, F. Everhart of New York City, Charles A. Kittle of Mount Kisco, A. D. Palmer, of East Orange, N. J.

The Christian County Coal Company, Taylorville, Ill. Capital stock, $25,000. Among other things, the company proposes to furnish electricity for heat, light and power.

The Oshkosh Telephone and Electric Service Exchange (new system), Oshkosh, Wis. Capital stock, $50,000. Incorporators: George Bauman, George W. Pratt, R. B. Evans, A. J. Barber and Bernard C. Gudden.

Indiana Electric Power Company of Goshen, Ind. Capital stock, $800,000. Directors: Gurney F. Coleman and Clinton D. Fireston, of Columbus, O.; Henry W. Kratz, of Norristown, Pa., and W. Ralph Wanner and Lew Wanner, of Goshen. The company proposes to construct and operate electric street railway lines in Goshen, New Paris and Nappanee, and between Goshen and Elkhart, and between Goshen and Nappanee.

An amended certificate of incorporation of the Municipal Gas Company of Albany, N. Y., has been filed. The amendment is that in addition to the objects for which the corporation was formed shall be included the manufacturing and using of electricity for producing light, heat and power in lighting streets, public parks and public and private buildings within the State of New York. And it is further authorized by the directors to purchase the stock of the Albany Electric Illuminating Company, and to issue in exchange its own stock. The company will increase its capital stock from $1,500,000 to $2,000,000.

Gallitzin Electric Light Company, Gallitzin, Pa. Capital stock, $20,000. Directors: J. L. Mitchell, A. A. Stevens, G. Lloyd Owens, Tyrone; Michael Fitzharris, William M. Smith, Gallitzin.

The Hewlett Voltaic Electric Company, Jersey City, N.J. Capital stock, $150,000. Incorporators: John J. Toffey and J. Herbert Potts, Jersey City; Cornell T. Griffith, New York. The purpose of the company is to manufacture, buy and sell batteries, electrical compounds and supplies, and to deal in patents.

The Madison Electric Light and Power Company, London, Ohio. Capital stock, $10,000.

Bluefield Telephone Company, of Bluefield, W. Va. Capital stock, $16,000. Incorporators: Geo. C. Hill, of Salem, Va.; A. M. Prince, Burke Prince, Geo. A. Shirkey, J. C. Darst, N. D. Maher and Jas. E. Mann, of Bluefield, and David E. Johnson, of Princeton.

The Concord Light and Power Company, Concord, N. H. Capital stock, $200 000.

The Arverne and Rockaway Beach Electric Company, for furnishing electric power for lighting and other purposes in the town of Hempstead, L. I., N. Y. Capital stock, $50,000. Directors: R. Florence and C. C. Vernan, of Arverne-by-the-Sea.

The Washington Electric Company, Chicago. Capital stock, $40,000. Incorporators: Victor W. Johnson, Oloaf R. Iverson and William J. Maddock.

The Chicago Electric Manufacturing Company increased its capital to $20,000.

The Automatic Telephone and Electric Company of Canada, Montreal, Can. The company's charter permits it to purchase, acquire and hold, sell and deal in any patents of invention covering any electrical device or apparatus, and to manufacture, lease, sell and deal generally in the articles covered by such patents of invention and embodying the principles of construction thereof, and to manufacture telephones, telephone instruments, switches and such other apparatus and appurtenances as are connected therewith, etc.

The West Michigan Electric Company, to generate electricity by water power at Lowell, Mich., and to transmit it to Grand Rapids, Mich., for distribution and use. Capital stock, $60,000. Incorporators: Edwin F. Sweet, Alfred C. Sekell, John E. More, of Grand Rapids; C. Jesse Church, of Greenville; Otto C. McDonnell and Charles A. Church, of Lowell.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 25, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

495,996. Closed-Conduit Electric Railway. William P. Patton, New York, N. Y. Filed July 15, 1892.

496;280. Electric-Railway Trolley. Wesley W. Pritchett, Odgen, Utah. Filed Nov. 2, 1892.

496,329. Telpher System. Charles J. Van Depoele, Lynn, Mass.; C. A. Coffin and Albert Wahl, administrators of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed May 15. 1891.

496,330. Electric Locomotive. Charles J. Van Depoele, Lynn, Mass; C. A. Coffin and Albert Wahl, administrators of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed Sept. 24, 1891.

ELECTRIC LIGHTS AND APPLIANCES.

496,366. Electric-Light Display System. Daniel McF. Moore and Charles M. Jacobs, New York, N. Y. Filed Nov. 22, 1892.

496,386. Electric-Arc Lamp. William H. Akester, London, England. Filed Sept. 9, 1892.

496,387. Electric-Arc Lamp. William H. Akester, London, England. Filed Sept. 9, 1892.

DYNAMOS AND MOTORS.

496,307. Combined Dynamo-Electric Machine and Water Motor. John O. Heinze, Jr., Lynn, Mass., assignor to the Heinze Electric Company, same place. Filed Oct. 15, 1892.

BATTERIES.

496,126. Storage-Battery. Frederick A. La Roche, Philadelphia, Pa. Filed March 25, 1892.

496,228. Dry Battery. Hugo Koller, Vienna, Austria-Hungary. Filed June 21, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

496,137. Mechanical Telephone. George H. E. Ricke, Cincinnati, Ohio, assignor of one-half to John A. Ringold, same place. Filed April 15, 1891.

496,224. Diaphragm-Holder for Telephones. Silas W. Holman, Boston, Mass. Filed Nov. 5, 1892.

MEASURING INSTRUMENTS.

496,309. Volt and Ampere Meter. John O. Heinze, Jr., Lynn, Mass., assignor to the Heinze Electric Company, same place. Filed Oct. 17, 1892.

496,312. Electric Measuring-Instrument. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Nov. 16, 1892.

496,371. Electric Meter. Francis Teague, London, England, assignor, by mesne assignments, to Joseph Sinclair Fairfax and Jasper Wetter, same place. Filed Feb. 2, 1892.

MISCELLANEOUS.

496,019. Electric Soldering. Elihu Thomson, Lynn, Mass., assignor to the Thomson Electric Welding Company of Maine. Filed Jan. 22, 1889.

496,020. System of Electric Distribution. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Dec. 29, 1890.

496,041. Electro-Mechanical Block-Signaling Apparatus. Murray Corrington, New York, N. Y. Filed April 26, 1892.

496,060. Electrical Stop-Motion for Knitting-Machines. George J. Manderfield, Royersford, Pa., assignor of one-half to J. M. Lewin, Samuel Lewin, U. S. G. Finkbiner and A. R. Saylor, same place. Filed Nov. 25, 1892.

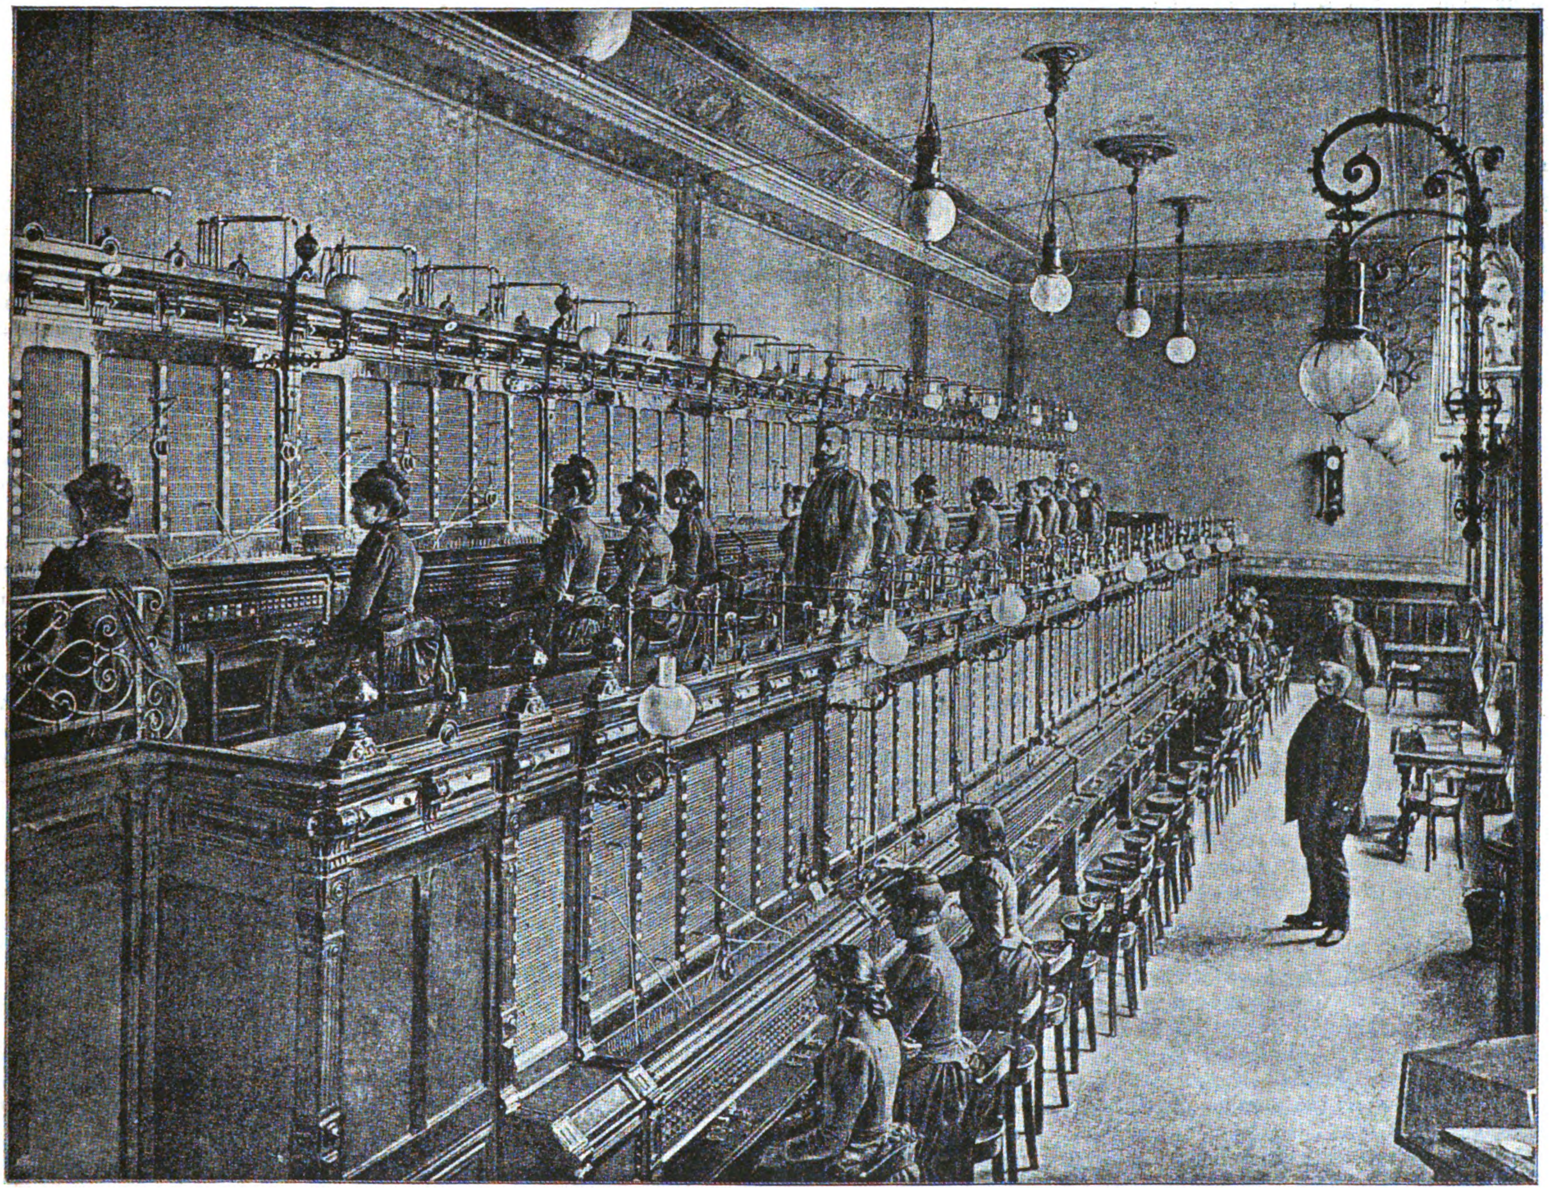
ELECTRICITY.

VOL. IV. NEW YORK. MAY 10, 1893. CHICAGO. No. 17



VIEW IN THE TELEPHONE EXCHANGE, BERLIN, GERMANY.

The Telectroscope.

Vision at Great Distances by Electricity.

BY LEON LE PONTOIS.[*]

I designate by this name an apparatus having for its object the transmission of pictures or views of moving or stationary objects at great distances, and as I use electricity for the purpose of obtaining this result, I call this apparatus a Telectroscope.

First let me say that by the transmission of pictures to great distances I do not mean the graphic transmission of sketches or writing as done, for instance, by the very ingenious invention of Prof. Elisha Gray, namely, the telautograph.

I intend to describe to you to-night the general outline of an apparatus that I have conceived for the purpose of seeing over as great distances as we hear by the long distance telephone.

There is, to a certain extent, an analogy in the mode of propagation of light and sound, therefore it seems rational to transmit the light rays over as great distances as we transmit the sound waves, by converting at a transmitting apparatus the rays of light into proportional electric undulations and reconverting at the receiving apparatus the electric undulations into rays of light of proportional intensity.

But the analogy between the telephone and the telectroscope is not so close as it seems to be. Sonorous vibrations affect our nerves of hearing by differences in the number of their vibrations per second, their loudness or their character. We can easily detect a certain sound amongst other separate sounds and even give a name to their harmonious groupment (what the musicians call a chord), because each sound or its harmonies vibratse one of our nerves of hearing and only this one.

Vision is the sensation produced on the nerves dispersed all around the retina by the rhythmic motion called light.

Each of the nerves can indistinctly vibrate for the different light radiations known as colors, and we have an exact idea of them because they differ one from the other by the number of vibrations per second.

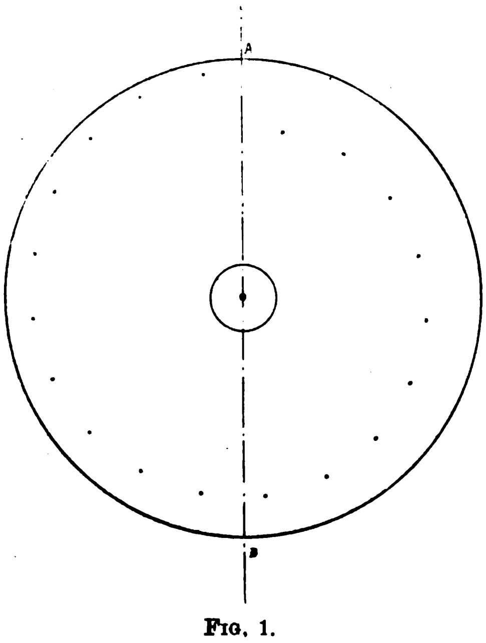


FIG. 1.

We see an object when it produces light by itself or reflects the radiations of another source of light, and we have a notion of its structure because from each point of its surface starts a ray of light affecting by its color and its relative intensity one of the nerves of the retina and only one.

Another object will affect this same nerve differently and will communicate to the cerebral matter a different impression, while on the contrary each of the nerves of hearing, similar to a resonator, always vibrates for the same sound and thus always transmits to the cerebral matter the same impression. This essential difference in the mechanism of vision and audition renders the realization of an apparatus to see at long distances more difficult than the realization in an apparatus to speak at long distance, because while we distinguish one object from another by differences in the number of vibrations and the relative position of its radiations, we differentiate one sound from another merely by the number of their vibrations per second.

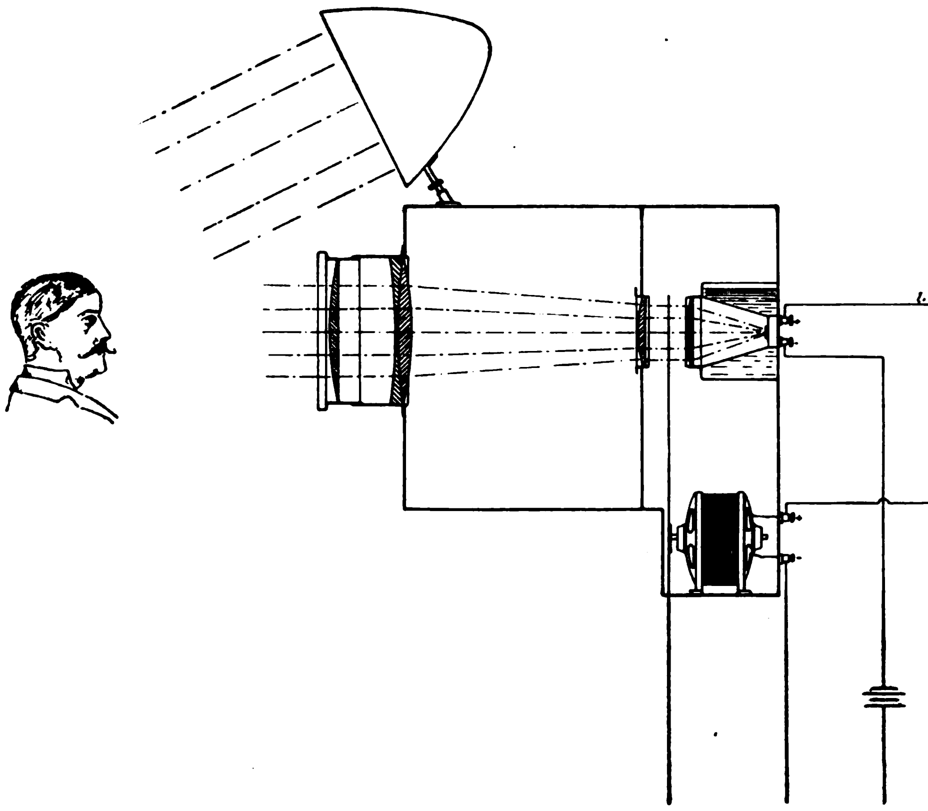

FIG. 2.

However, a few attempts have been made in this fascinating field, and among them I must recall to your minds the telephote of Prof. Bidwell. This apparatus for producing pictures or writing at a distance is an application of a property of selenium in combination with the chemical telegraph. In this telegraph a colored mark is made at a distance when current is transmitted, and fac-simile of the original may be produced by a series of dots and lines. A continuous current of greatly varied intensity would result in similar variations in intensity, and such a variable current is producible by changes in the resistance which may be produced by light acting upon selenium.

Mr. Shelford Bidwell made an apparatus for this purpose. The transmitter is a dark box, one end containing a selenium cell forming part of the line circuit, and facing a small hole at the other end; the box is mounted on an axis so as to move up and down, each upward motion corresponding to one rotation of the receiving cylinder, and so to one line on the drawing produced. The box also moves sideways at each stroke, to correspond to the distance of the lines apart. The face of the box corresponds to the screen of a magic lantern, and the picture to be transmitted is thrown upon it continuously, so that the pin hole is, so to speak, an eye by which the selenium cell looks the picture over, and receives impressions from each part successively as it traverses over the space filled by the picture. When a dark line is thrown on the hole the resistance increases, while a white portion reduces it. The transmitter is really a differential instrument, it receives the line current at one terminal and that of an opposed local battery at the other, the line being also connected to the other pole of the battery and resistance so arranged that the local battery acts and makes a mark whenever a dark line is to be produced, and thus the travelling style produces either no action at all or colored lines varying in depth of tone in correspondence with the amount of light falling upon the selenium cell from the distant transmitting illuminated picture.

It is a well-known fact that the impressions made on the retina by the rays of light emitted or reflected by a body do not disappear instantaneously if an opaque body is suddenly placed between the eyes and the luminous body. This persistence of vision can be explained by the fact that, vision being caused by vibratory movements imparted to the optic nerves by the rays of light, on account of inertia these vibrations have a tendency to persist a short time after the cause that has originated them disappears.

On account of the same principle of inertia, the impressions do not take place on the retina as soon as the light rays strike it. It takes a certain time before the optical nerves vibrate synchronously with the rays of light. That is why we cannot see a body when it passes very rapidly before our eyes, and we have in optics the retardation of vision as we have in electricity the capacity and the self-induction. That is why we can see distinctly and continuously an object placed on the rear of a fly wheel turning very fast though the spokes cover successively the different points of its surface, and it does not matter whether the object has a movement of its own or not, provided of course that the speed of this movement does not exceed a certain limit. Quite a number of optical instruments—rather toys—have been constructed on this principle: the taumatrope, the phenakistiscope, the kaleidoscope, so universally known that they do not need to be described.

The only difference existing between this last instrument and the Edison kinetograph lays in the fact that the pictures that in the phenakistiscope represent a different position of a body while moving are drawn by guess (so to speak) while in the Edison kinetograph they really represent a different phase of the movement because each of them is a photograph taken in the one-ninety-ninth part of a second, showing a different position occupied by a moving body. Forty of these pictures are taken in a second, and their rapid succession before the retina gives a perfect illusion of the motion.

---

[*] Read before the Pittsburg Electric Club.

The impression is striking and one would vow that the picture is really moving. Consequently the kinetograph stores and reproduces the impression made on the retina by moving objects as the phonograph stores and reproduces the human voice.

I have spoken at some length about the persistence of vision because the telectroscope is partially based on this fact.

The transmitting apparatus is made of a dark box provided with lenses like a camera. At the focus where the sensitive plate is ordinarily exposed to the action of light is placed an open disc made of very thin and light material, mounted on a shaft. This disc is shown in part in Fig. 2. Pin holes, about $\frac{1}{100}$ of an inch in diameter, are perforated near the periphery on concentric arcs of circles, the difference between the radius of two successive arcs being $\frac{1}{100}$ inch, while the distance between two holes is equal to the width of the image painted by the rays of light on the superior part of the disc.

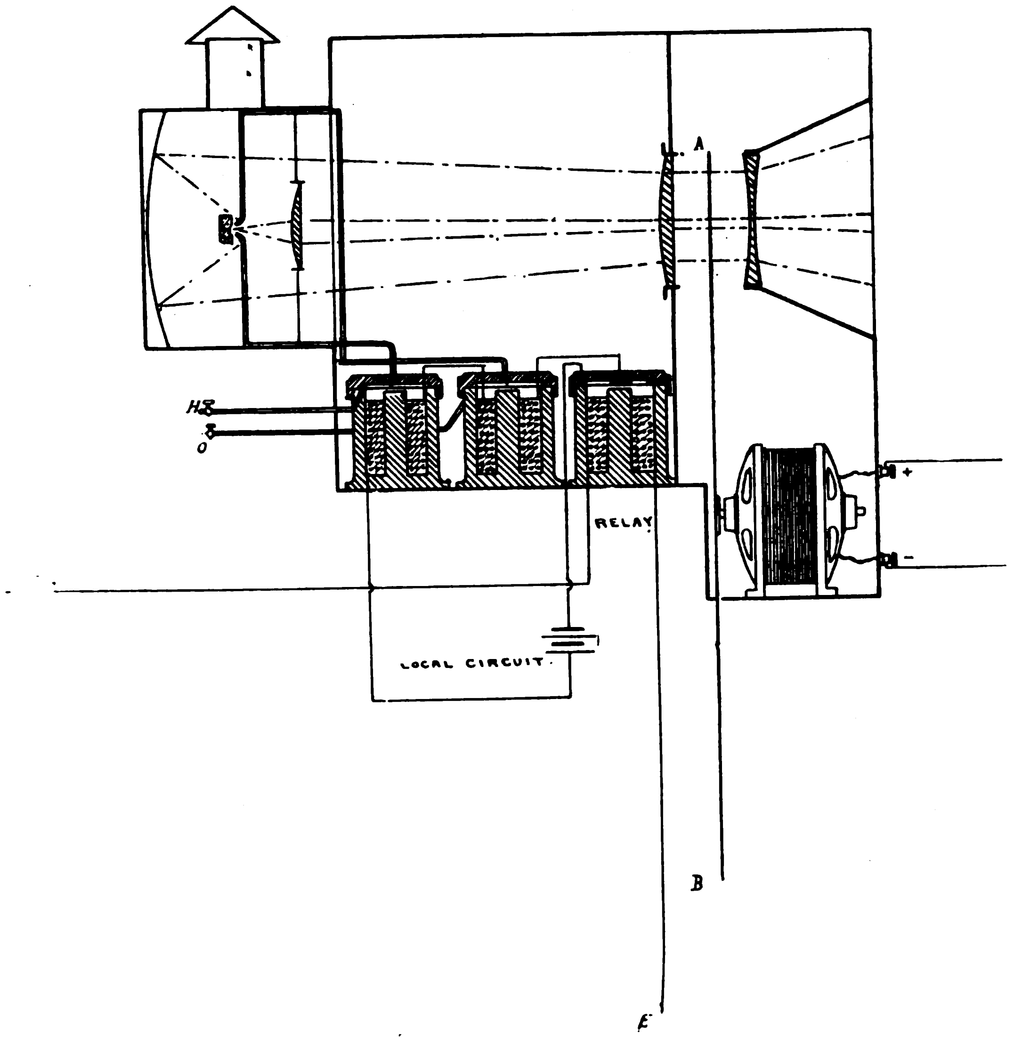

FIG. 3.

The number of the perforations is such that the total of their diameter is equal to the height of the image. The holes being thus dispersed on the surface of the disc, and the disc revolving, the perforations traverse the surface of the picture according to different concentric lines and the rays of light pass successively through the disc when the perforations are moving past them.

The conversion of the rays of light into electric currents of proportional intensity is effected by a special selenium cell of an extreme sensitiveness acting by the influence of the heated light.

There has been considerable debate as to whether the changes in the resistance of the selenium are due to the light or to the heat. In fact, I believe as the result of my own experiments that in most of the cases the increasing in the intensity of the current is due to the combined action of both

Send a beam of light through a tube containing a solution absorbing the hot rays, alum for instance, before directing it upon the selenium, and let us suppose that the beam of light falling upon the selenium has exactly the same temperature as the selenium.

The resistance decreases in a certain value or seems to decrease—but how can we admit that in the conditions of the experience the light has modified the molecular structure of the selenium? In fact, the change of resistance is apparent, and the current flowing through the circuit has a greater intensity, not on account of a diminution in the resistance of the selenium, but because the undulatory movement called light has imparted an excess of speed to the undulatory movement called electricity.

I have demonstrated that in the mechanical theory of electricity the E. M. F. expresses the speed of the undulatory movement called current.

Consequently, the excess of speed imparted by the light to the vibrating atoms of the selenium will cause an increase in the E. M. F. of the battery and therefore in the current.

I am convinced that even if a galvanometer sensitive enough could be constructed, one could possibly detect the presence of a current merely due to the action of light falling upon the selenium.

If now the hot lights act directly upon the selenium the variations in strength of the current are much greater, but the action of heat differs from the action of light.

While the light sets up, we might say, an additional E. M. F. heat causes really a diminution of resistance due to the fact that selenium being a crystalline body the contact between its surface and the electrode on which it is deposited is far from being perfect, and is rather a microphonic contact that can be modified by expansion or contraction.

It does not seem at first possible that such modifications can take place instantaneously, but we have learned by recent discoveries how great is the sensitiveness of matter to the smallest variations in the streams of radiant energy. The changes of temperature are attended with great molecular changes, modifications of structure and properties, which occur with a rapidity comparable only to the speed of light.

The reason of this lies in the fact that each molecule of matter is the centre of action of many forces, a centre modified instantaneously by any change of relation among those forces.

As a consequence of this, a beam of obscure heat of variable intensity must modify the resistance of the selenium, and in fact it does so, but the action is more complete if the falling beam of heat is luminous, because the heated light penetrates more deeply through the selenium whose molecules are probably more diathermanous for the luminous rays than for the obscure rays.

Consequently the variation that will occur in the resistance of the selenium cell, upon which falls a beam of heated light, will be greatly increased if the difference between the temperatures of the selenium and the rays of light is as great as possible.

In order to obtain this result I direct the light of a projector located on the top of the apparatus towards the object whose picture is to be transmitted to a distance, and I use preferably a source of light giving very hot rays—calcium light for instance; thus the temperature of the light rays reflected by the object and directed by the lenses on the surface of the selenium is higher, and therefore the effect is increased, but in some cases it is not possible to raise the temperature of the illuminating rays above a certain limit. To remedy this inconvenience, I cool the selenium cell by placing it inside a conical cavity forming part of a receptacle containing a cooling mixture; the cone is closed at its base by a lens facing the disc, and directed at its focus where the selenium cell is exposed, and the rays of light pass through the perforations of the disc.

By this disposition the difference in the temperature of the heated light rays and the selenium is as great as possible, and consequently the variation of the current is a maximum.

The selenium cell is made of strips of tinsel foil separated by narrow strips of dry paper—the pile is held by a clamp, and its face covered by a coating of selenium, which in turn is covered by a very thin coating of lampblack.

With the apparatus thus constructed, it can be easily understood that if the disc is caused to revolve each of the rays of light forming the picture will successively set in the line currents of varying strength. These currents act at the receiving apparatus upon a microphonic relay acting on the telephone receiver, shown in Fig. 3, modified by the addition of a narrow chamber placed between the disc and a cover hermetically closing the telephone.

One of the chambers is full of oxygen, brought in by a pipe, and the other is full of hydrogen.

On the top of the covers is tubing properly adjusted and provided with regulating valves.

The two gases are brought under pressure near the surface of a cylinder of carbonate of calcium.

The variations in the strength of the current of the microphonic relay, cause pulsation of the diaphragms.

But those pulsations, even if they are of a molecular nature, impart to the molecules of the gas an excess of speed, causing proportional variations in the intensity of the oxyhydrogen light. Lens and a reflector concentrate the light on a ground glass or screen after having previously passed by one of the perforations of a disc absolutely similar to the disc placed in the transmitting apparatus.

Then, according to the position occupied by the perforation on the surface of the disc, the beam of light passing by this point makes a more or less luminous point some place on the depolished glass.

But as the two discs are evolved synchronously by the two pulsating current motors, whose pulsations are controlled and even created by the vibrations of a tuning fork, when the light of the receiver passes through a certain perforation of the receiving disc one of the rays of light emitted by the object passes by the same perforation of the transmitting disc. If the disc turn slowly, each ray of light emitted by the different points of the object placed in the field of the transmitting apparatus is converted into an electric current of proportional intensity, which current is re-converted at the receiving apparatus into a beam of light of proportional intensity, and if a sensitive plate was substituted for the ground glass a picture would be taken of the object placed in view of the transmitter after a complete revolution of the disc. But if the discs are revolved at a rate of ten revolutions per second, each point of the depolished glass is more or less luminous or dark ten times a second, and on account of the persistence of vision the retina is not affected by the successive disappearance of the points, which taken together reproduce exactly the object placed in view of the transmitter.

It does not matter even if this object moves or not, because the image of the receiver is constantly modified by its movements.

Atomic and Molecular Motions.

BY A. E. DOLBEAR.

That all kinds of matter are resolvable into ultimate particles, which by common consent are called atoms, is now so well settled that the sciences of both chemistry and physics are founded upon that idea and ultimate explanations of all phenomena are now believed to be due to the inherent qualities of such atoms. The knowledge which has so well established this atomic theory of matter has been nearly all acquired in this century. Ask any chemist for his reasons for holding by this theory, and he will reply that he can isolate the elements, and by no known process yet discovered can they be more finely divided that he can measure their individual magnitudes, can weigh them, prove their existence in the sun and stars, and that the weight of such cumulative evidence is very great. If one goes among those who style themselves philosophers, yet who have only apriori reasons for believing in atoms, he will hear it often asserted that the atomic theory is very old, that Democritus and Lucretius, old Grecians, taught that philosophy two thousand years ago, and it is true they did, but the reasons given for holding to such tenets are not such as any modern scientific man can give any weight to, and the reasons now given for the atomic theory are of such a nature that none of the ancients could have understood them without the scientific knowledge of this nineteenth century. In all historic times there have been thoughtful men who have sought for an explanation of the universe as they saw it, and have guessed how it might be. Some have guessed one way and some another way, but none of them gave a sufficient reason. Of course, some would guess nearer right than others, but such guessing gives no claim to the discovery, or entitles one to be considered the founder of a philosophy that had to wait two thousand years for later men and different methods to substantiate it. This is true in other departments of knowledge as well. Whewell, the historian of the sciences, tells us: "No discovery of general laws, no explanation of special phenomena, rewarded the acuteness and boldness of these early students of nature." And again: "They arrived at no doctrines from which they could deduce by sound reasoning such facts as they saw." From which one may fairly infer that modern science is not in any way founded upon ancient speculations, but upon laborious painstaking experiment and verification. By far the larger part of what we have is the work of this century. The first evidence having a real scientific character bearing upon the existence of atoms was given by Dalton, an English chemist who died about fifty years ago, but since his day a great body of corroborating evidence has been collected. A number of persons have devised methods for measuring the size of atoms, and their determinations agree very well. For instance, the atoms of the element hydrogen are found to be about one-fifty-millionth of an inch in diameter; other elements, some a little larger and some smaller. How such minute things can be measured even approximately has been a puzzle to many persons, and not a few have doubted that it could be done at all. I once had such a skeptical person tell me he doubted very much whether anybody could measure to the thousandth part of an inch. I sat down with a common wire gauge, and very soon convinced him of that, though it was admitted with some reluctance. Every one has admired the beautiful play of prismatic colors seen on the surface of a soap bubble. As the material of the bubble flows down its sides, it gets thinner and thinner at the top and thicker at the bottom. When a certain degree of thinness is reached by the downward flow, the colors begin to appear and in the same order as they are in the rainbow. A second, a third ring of such rainbow tints is formed, and so on, sometimes as many as a dozen all moving down the sides of the bubble, but at last no further colors are added, but beyond the last purple tint there is a white circle, and then in a good persistent bubble may generally be seen forming next to the bowl of the pipe a very black patch with a ragged edge. In the course of two or three seconds after this is formed the bubble bursts. Now by attending to the phenomena in their order one may get a good lesson on the minuteness of the molecules of water out of which the bubble is formed. The colors are produced by the interference in the light rays that are reflected from the two surfaces of the bubble, so that when the thickness of the film is such that the distance through and back is equal to half a wave length of light the interference can take place and colors appear. The length of a wave of blue light is found by measuring in other ways to be about one sixty-thousandth of an inch, and as the thickness of the bubble where the last colors appear is but the fourth of the wave length of the light, it follows that at that place the thickness of the film is

$$\tfrac{1}{60000} \times \tfrac{1}{4} = \tfrac{1}{240000} \text{ of an inch.}$$

It is found in other ways which I cannot dwell upon here that the thickness of the black patch is only one-fortieth of the thickness of the film where the color last shows, and that will give for the thickness of the film

$$\tfrac{1}{240000} \times \tfrac{1}{40} = \tfrac{1}{9400000} \text{ of an inch,}$$

yet the film has tensile strength enough to hold the weight of the bubble for a short time. If there were but a single thickness of molecules, it does not seem in any degree probable they could support such a weight as they do. One may now speculate if he cares to as to the probable least number that could hold it together any time. If he thinks that a film of five molecule thickness might do it, he will then have for the diameter of the water molecule,

$$\tfrac{1}{9400000} \times \tfrac{1}{5} = \tfrac{1}{47000000} \text{ of an inch.}$$

If he thinks it needful he will make the molecule nearly the hundred-millionth of an inch in diameter. In any case one can see he is reckoning with millionths of an inch.

Everybody knows that water is composed of hydrogen and oxygen combined together, and a chemical combination of atoms is called a molecule. When only two or three atoms are thus combined, the molecules thus formed cannot be very much larger than the constituent atoms, but some molecules contain as many as a thousand atoms, and such molecules in all probability have a diameter as much as ten times the diameter of its constituent atoms, for the cube of ten is a thousand. So one must think of the molecules of all such matter as we can see and investigate as having definite magnitude, and as possessing properties which are the resultant properties of the atoms that compose them. But if one would perceive still clearer the extreme minuteness of these particles, let him compute the number there must lie in, say a cubic inch of water. If the diameter given is, say fifty millionths of an inch, then of course fifty millions in a row would reach but an inch, and the cube of fifty millions would be the number in a cubic inch. This written out gives the number of 125 followed by twenty-one cyphers. If one fancies that kind of work he may compute how many molecules there are in a cubic foot in the earth and in the sun. In the atmosphere at ordinary pressures there can hardly be less than a million million millions in each cubic inch, and when in the common air-pump one reduces the pressure to one millionth of the common air pressure, he then has left in the so-called exhausted vessel no less than a million millions in every cubic inch. So that one can easily see that a perfect vacuum cannot be obtained with every air pump, nor indeed with any device one can possibly make. Matter exists in all degrees of condensation, and for convenience physicists have adopted such words as solids, fluids and gases to represent the various states of aggregation and freedom among molecules. Where the molecules are free, as in the air and in gases in general, they move about and bump against each other, rebounding after collision like billiard balls, and that is the way one must think of the air in this room, the average distance each molecule must move between impacts being somewhere in the neighborhood of the one-two hundred and fifty thousandths of an inch. As one rises in the atmosphere, the density becomes less and less, and at the height of a hundred miles from the surface of the earth the molecules are so far apart that one might have to move a million miles before coming in collision with another molecule. It has been computed that at the height of three hundred miles an air particle might travel freely from one star to another, so it is thought quite probable that the earth is slowly losing its atmosphere by molecular impact forcing some away with a velocity too great for gravitation to return it, and also that the earth is picking up other free-roving molecules in the space it travels in very much as it now captures meteors. The spectroscope shows that the space through which the earth is now moving contains benzine and alcohol in small quantities.

We have obtained our knowledge of most of the properties of matter by studying the phenomena exhibited by bodies of visible magnitude. That a body will continue in its state of rest or of motion until some other body acts upon it, that compounding forces does not alter the value of either, and that action and reaction are equal: these laws are as applicable to a small body as to a large one, to molecules as well as a mass as big as the earth or the sun, and it is through the recognition of this that the growth of physical science has lately been so rapid. Indeed, it may be said that what is called molecular physics is simply the application of mechanical laws to molecules, and the explanation of any phenomenon is given when the mechanical antecedents of that phenomenon are pointed out. Although large and small bodies obey in their motions the same fundamental mechanical laws, it is found convenient to make some distinctions. Thus, when a body large enough to be easily seen has a visible motion from one position to another such motion is called *mechanical* or *translatory*; whereas a molecule, too minute to be seen but moving in a similar way, is said to have *free path* motion, and such free path motion is the kind going on all the time among the particles of air or of any gas. Another kind of motion both large or small bodies may have is *vibratory*, this is distinct from the kind called oscillatory, which is the kind of motion a body like a swinging pendulum has. The true vibratory motion of a body is that due to a change in form as when the prongs of a tuning fork vibrate, or a bell while sounding; the whole does not necessarily swing to and fro, it is the motions of a part of a body with reference to some other part of the same body. A good idea can be formed of this by imagining a flexible ring of wire or of rope. Crowd its sides together and it will elongate in the opposite direction, and when the same sides are drawn out the parts that were furthest apart will be drawn together. If the body were an elastic body and it should be struck, it would go through a series of such motions, that is, it would vibrate. A third kind of motion is called *rotary*. This does not imply any change of position in space of the center of mass of the body, nor of change of form. One can easily see that a given body might have all three of these motions at the same time without interference. For instance, suppose a common hand-bell be struck, if it gives out a sound we know it vibrates though it be held steadily in the hand. If one suspends it by a long string to the ceiling, he can give it a spinning motion while it sounds, and in addition he can swing it through a long arch, giving it a translatory motion, each of which kinds of motion it will retain independent of either of the others. A bullet shot from a rifle has a translatory and a rotary motion, and all free moving bodies if elastic have more or less of these three kinds of motion. All the various movements of even the most complex machinery may be reduced to these three kinds of motion, either simple or compounded. And what is true of masses of matter large enough to be plainly seen and studied must be assumed to hold true of bodies too minute to be seen. Is it not so obvious as not to need argument that mere size can make no difference in the quality of motion in a body?

Apply this then to the molecules of the air in this room; they are in a gaseous state, that is, are not in contact with each other; they are elastic, for all gases are elastic. And the fact that the air exerts a pressure of nearly fifteen pounds to the square inch shows that they are bumping against each other and the walls of the containing vessel, for the pressure varies as the amount of air acting. The molecules have a free path, that is, their translatory motion, and as they are also elastic, when they collide they *must* vibrate in the way stated. I emphasize the word must because I want each one of you to see the necessity for it if the laws of mechanics, found to hold true for bodies of visible magnitude, hold true for smaller bodies. If, however, anybody is not satisfied with such a reason and thinks it possible that small elastic bodies on impact may not thus vibrate, I will give him other evidence presently that cannot be gainsaid.

(To be continued.)

American Electro-Therapeutic Association.

At a meeting of the Executive Council of the American Electro-Therapeutic Association, held at the office of the Secretary March 2d, 1898, the following resolution was adopted:

"*Resolved*, That the Secretary be instructed to prepare a circular to send to Fellows of the Association, to members of the medical profession, to electrical experts and to manufacturers of electrical appliances for medical work, containing titles of all the committees, the members serving on them, with their addresses, and the matter prepared for discussion and investigation by each committee.

"And that manufacturers be asked to communicate with the members of the different committees, if they desire to have their instruments examined and tested, stating their claims and merits.

"And that physicians, electrical experts and manufacturers be asked to co-operate in making suggestions and in relating their experience and preference for instruments, with reasons and data.

"And to mail this circular to all members of the Association, manufacturers, medical journals and to others who are known to use electricity extensively, asking for a speedy reply either to the Secretary or to the members of the respective committees whom it concerns."

In accordance with the above resolution the following committees have been appointed:

COMMITTEE ON STANDARD COILS.

Dr. W. J. Morton, 19 East 28th street, New York.

Dr. A. H. Goelet, 351 West 57th street, New York.

Dr. Wm. F. Hutchinson, Providence, R. I.

Dr. G. Betton Massey, 212 South 15th street, Philadelphia.

Mr. A. E. Kennelly, Chief Electrician, Edison Laboratory, Orange, New Jersey.

COMMITTEE ON STANDARD METERS.

Dr. Margaret A. Cleaves, 68 Madison avenue, New York.

Dr. H. E. Hayd, 78 Niagara street, Buffalo, N.Y.

Dr. Wellington Adams, 2741 Olive street, St. Louis, Mo.

Dr. W. F. Robinson, 214 State street, Albany, N. Y.

COMMITTEE ON STANDARD ELECTROSTATIC OR INFLUENCE MACHINES.

Dr. W. J. Morton, 19 East 28th street, New York.

Dr. J. H. Kellogg, Battle Creek, Mich.

Dr. G. Betton Massey, 212 South 15th street, Philadelphia.

Dr. Margaret A. Cleaves, 68 Madison avenue, New York.

COMMITTEE ON CONSTANT-CURRENT GENERATORS AND CONTROLLERS.

Dr. W. J. Herdman, 48 East Huron street, Ann Arbor, Mich. Rheostats and Dynamo Current Controllers.

Dr. Robert Newman, 68 West 36th street, New York. Primary Stationary Batteries.

Dr. Frederick Peterson, 201 West 54th street, New York. Secondary Batteries and Primary Portable Batteries.

COMMITTEE ON STANDARD ELECTRODES.

Dr. A. Lapthorn Smith, 248 Bishop street, Montreal, Canada.

Dr. R. J. Nunn, 119 York street, Savannah, Ga.

Dr. Charles R. Dickson, 263 Victoria street, Toronto, Ontario.

Personal.

A dispatch from Naples states that the Italian Minister of Public Instruction has nominated Lord Kelvin, better known as Sir William Thomson, to be a member of the Naples Academy.

Mr. L. H. Rogers, of Boston, has been appointed assistant general manager of the Brush Electric Company and general manager of the Sperry Electric Railway Company at Cleveland, Ohio, and has removed his family to Cleveland. He had been for several years connected with Eastern offices of the General Electric Company, and is well and favorably known in New England.

Practical Talk on Meters.

Mr. White, the Superintendent of the Meter Department of the Brooklyn Edison Company, delivered a practical lecture on electric meters before the Electrical Section of the Brooklyn Institute of Arts and Sciences on Friday evening last. He showed the workings of various types of both American and European meters, and made it plain how the electrical current can be accurately measured.

Mr. White was introduced by Mr. W. S. Barstow, the General Manager of the Brooklyn Edison Company, who has lately returned from a tour of inspection of foreign stations. Mr. Barstow described briefly the various meters in use abroad, those in Venice having particularly attracted his attention. They use there a small meter for every fixture. It is in reality only a small clock with solenoid switch. A number of lamps of a given candle power, say 16 C. P., are attached to the fixture. When the current is turned on the clock starts and registers the length of time the lamps burn. A little figuring tells how much current the consumer has used—provided he has not substituted 50 C. P. lamps for his regular allotment of 16 C. P.

Mr. White explained in detail a number of designs of meters which he exhibited, among which were one of his own invention, soon to be adopted by the Brooklyn Company, and one of the latest of Lord Kelvin's inventions, said to be the first and only one imported to this country so far.

BOOK NOTICE.

HOW TO THINK IN FRENCH. BY CHARLES F. KROEH, A. M., PROFESSOR OF LANGUAGES IN THE STEVENS INSTITUTE OF TECHNOLOGY. PUBLISHED BY THE AUTHOR. Lordon and Hoboken, N. J. 140 pages. Price, $1.00.

The fundamental idea contained in this work is aptly called by Prof. Kroeh the "living method," in which the student associates his actions with the French phrase describing them and avoids thinking of them in English or making a literal translation. The author considers it impossible to speak in French and at the same time think in English, and that the only way to accomplish this is "to live in French." This method is intended as supplementary to the Natural Method in which all references to English are entirely dispensed with, and the idea of thinking in French is by no means confined to class exercises but may be carried on at any time.

The preparation of phonograph cylinders is in progress which will contain the exact pronunciation of all the fundamental sentences contained in this book. The "living method" commends itself as the most natural and feasible method of acquiring a speaking knowledge of a foreign language, and is highly endorsed by teachers who have adopted it in class work.

The Wonders of Electricity.

J. H. Mason, inventor of Mason's new battery system of electric lighting and power, will lecture in Rochester Avenue Church, Brooklyn, Wednesday evening, May 10.

Mr. Mason is thoroughly posted on the practical applications of electricity and his audience is sure of an evening of instructive entertainment.

The Central Railroad Company of New Jersey has had one of its cars equipped with the Young-Muskowitz railway electric lighting system, and it has been run over three thousand miles of track as a test with satisfactory results. The light is generated by a one-horse power dynamo, which is run by a system of shafting, sprocket wheels and chain belts, which connect with the axle of the car. A storage battery takes up surplus electricity and supplies current when the car is not running. This battery will feed the car four hours.

ELECTRICITY.

The Popular Electrical Journal.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

United States, - - - -	$2.50
In Clubs of Five or More, - - -	$2.00
Foreign Countries, - - - - -	$4.50

ADVERTISING RATES:
As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

Entered at the N. Y. Post Office as Mail Matter of the Second-Class.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Constant Current Transformers. The lecture by Prof. Crocker on Dynamotors, an abstract of which is given elsewhere, suggests some useful applications of these machines, which have so far been very little used outside of experimental purposes. There is one application for which these machines seem to be admirably adapted, and that is for methods of regulation or where small differences of potential are required. This is easily accomplished by connecting the secondary winding of the machine in series with the main line, and thus raising or lowering the pressure on the main according to the ratio of the transformer circuits. In order to secure a variable range of pressures several machines would be necessary, but this extra cost should be more than offset by the loss involved in the use of large resistances or feeder equalizers. Another application of this principle which has lately been patented is a combination of several auxiliary machines to avoid the use of resistances in charging storage batteries. The usual method employed for this purpose is to run the generator at the maximum pressure required for the batteries at the end of the charge, and start in with a large resistance in series which is gradually cut out as the batteries become charged.

In the other case several auxiliary machines, say four, are run directly connected on one shaft, two as motors and two as generators, and their potentials vary by a few volts. The main generator can then be run at the average pressure of charging, and by using the small machines in series with the main line a range of pressure of five steps, two below and two above the average, is secured. This method we believe has been found very successful in practice, and where a large number of batteries are to be charged, effects considerable saving over the use of a rheostat.

There appears to be a considerable field for these machines, and numerous new applications will undoubtedly arise as soon as their efficiency is improved, as it is pretty sure to be by careful designing and good workmanship.

* * *

A New Electrical Instrument. An instrument by means of which we may obtain views of distant objects or places by transmitting pictures of the same by an electric current is the subject of a lecture by Mr. Le Pontois before the Pittsburg Electric Club, and will be found elsewhere in this issue. The operation of seeing over as great distances as we now hear by the telephone seems almost too difficult to be classed among the possibilities, yet sufficient advance has been made upon an instrument of this character to give color to the belief that its perfection is only a matter of a short time.

The operation of the instrument described is based upon the property of selenium by virtue of which its resistance is affected by light, and by submitting a selenium cell successively to the various degrees of light reflected from the object to be pictured a current of a pulsating nature is produced, whose pulsations correspond to the various light waves reflected, and are transmitted over the line and reproduced at the receiving instrument.

It should be understood that this instrument differs fundamentally in principle from the kinetograph, in which a permanent record is obtained of the object by means of photography, and which is not an electrical instrument. In the telectroscope the image is reflected as in a looking-glass, and transmitted over a wire without the use of photography or any permanent recording of the picture.

* * *

Atomic and Molecular Motions. We commence in this number an interesting paper on the accepted theory of atomic and molecular motions, contributed by Prof. Dolbear. As modern science is based upon the atomic theory, it stands at the foundation of all our scientific knowledge at the present. The relations which this theory bears to the phenomena of heat, light, electricity, etc., are treated in a solid though simple manner, and the paper contains in concrete form information which would require considerable research to obtain.

* * *

Conspiracy and Theft. The charges of conspiracy and theft made by the Westinghouse Company against the General Electric Company and its agents are summarized elsewhere.

It is as yet too early to discuss the merits of this case, but there are a few facts which stand out clearly.

Mr. W. J. Clark, one of the accused officials, charges that the entire move is one for stock-jobbing purposes. This is monumental nonsense; and considering that Mr. Clark is known to be possessed of at least an average intellect, the only conclusion is that he was very badly rattled.

In the first place the interests of the Westinghouse Company would not be bettered in any degree by a collapse in General Electric stock, such as was recently threatened. The officials of the former company would not aid in any attack which had for its object the placing of the stock of any electric company before the public as unsafe investments. The reasons for this ought to be plain to any of Mr. Clark's office boys.

In the next place, the charges made are of a very grave character, and no company would dare to make them for stock-jobbing purposes. A failure to produce satisfactory proof would render the Westinghouse Company liable for more damages than its gross earnings from this year's business. Moreover, the District-Attorney of Allegheny County, Pa., is presumably a man of average legal attainments, and has weighed carefully the information laid before him.

* * *

Mr. Morris W. Mead has made an emphatic denial of all the charges brought against him by the Westinghouse Company. Those who know Mr. Mead best will accept his statements as true, and it will be a pleasure for Electricity to state, when the matter is finally cleared up, that Morris Wideawake Mead was not in it.

THE slump in General Electric to **58** must have been a surprise to the guileless New Englanders who have placed their faith in Mr. Coffin's assertions that the stock was going to 150. ELECTRICITY's charges have been borne out to the letter, and we are not surprised. The intrinsic value of the stock has not yet been established, but we place it far below 58.

* * *

ELECTRICITY is not prepared to assert that Mr. Coffin and his agents are guilty of the charges preferred against them. We are prepared to assert that the history of the Thomson-Houston Company has been such that no one will be surprised if the charges are fully substantiated. The stealing of other people's ideas has been a common occurrence with this company, and its employees have been taught that roguery was a virtue which would be rewarded.

* * *

"WITH the prospective advent of new lamps, consumers and supply dealers should not forget their duty. The General Electric Company will soon be on its knees begging for trade, and for the services of the middle-man in securing it. But non-infringing lamps should be the only ones used or sold."—ELECTRICITY, *March* 22.

The begging will soon begin, and every enemy of monopoly should do his duty.

This is the slogan: Let no man purchase one dollar's worth of supplies of the Trust or of the Trust's agents which can be purchased elsewhere.

The Prophecy Fulfilled.

General Electric's Rottenness is Proven.

General Electric was depressed on the circulation of a number of disquieting rumors. There is little reason to doubt that since the recent flurry in money the accommodation usually obtained by the company with the banks in this city and in the East has been curtailed. It is also understood that the company will have to compete with a new patent about to be introduced, which may involve a complete change in the system of supplying incandescent lights.—*Brooklyn Eagle.*

All sorts of unfavorable rumors are in circulation respecting General Electric. There appears to be no doubt that the company is in need of funds, which it is unable to obtain in the present condition of the money market.—*N. Y. Advertiser.*

There is a general impression in Wall Street that the Edison General Electric Company is in need of funds. Serious competition is having its effect, and the steady decline of the stock creates no feeling of surprise.—*N. Y. Journal.*

The General Electric thieves have grown rich by their loaded dice manipulation, at the expense of Wall Street and the outside public, and now their fleeceless victims strew the highways and byways, and the besom of destruction is sweeping away the rubbish that the thieves had so long cracked up so high to delude people into buying.—*Daily Investigator.*

The question having beeu raised in Pottsville, Pa., whether the city council had power to abrogate the contract now in force with the Edison Illuminating Company, and to award a new contract for lighting the borough, Borough Solicitor Matten has submitted to the council his opinion that the contract authorized by council with the Edison Electric Illuminating Company is within the scope of its legislative powers, and binds the corporation of the Borough of Pottsville for five years from February 10, 1892, if said company faithfully comply with the covenants contained in said contract.

CONSPIRACY AND THEFT.

ORDERS OF ARREST FOR PRESIDENT COFFIN AND SOME OF HIS SUBORDINATES.

THE WESTINGHOUSE COMPANY'S GRAVE CHARGES.

Our readers have already been made familiar through the daily press with the charges made by the Westinghouse Company at Pittsburg, against the General Electric Company and its paid accomplices, of the theft of various blue prints and drawings from the Westinghouse factory, and their subsequent use by the General Electric Company.

It is evident that a grave crime has been committed, and that the actual facts in the case cannot be long concealed.

Civil suits have already been begun in Pittsburg and in Salem, Mass., for the recovery of the stolen drawings, and District-Attorney Burleigh, of Allegheny County, Pa., has issued orders of arrest for President Charles A. Coffin, W. J. Clark, E. W. Rice, Jr., W. H. Knight, and M. H. Hamilton, of the General Electric Company, on the charge of conspiracy. Morris W. Mead, Frank Carey (a draughtsman), John Butler and C. C. Christian, of Pittsburg, have already been arrested and released on bail.

It seems that in July last Frank Carey was employed as a draughtsman by the Westinghouse Company. He had previously been employed in the Lynn factory of the T. & H. Company.

The Westinghouse Company became aware some time ago that drawings and plans were being systematically stolen from their office, and detectives were called in.

It is claimed now that Carey was all the time in receipt of a handsome salary from the General Electric Company, and had in addition a large corruption fund at his disposal; that his arrangements were made directly with President Coffin and W. J. Clark; that the drawings were traced to the desk of E. W. Rice in the Lynn factory, and that W. H. Knight, when called upon by a deputy sheriff, admitted that certain Westinghouse drawings were at that time in use in their draughting room.

The officials of the Westinghouse Company have made the following statement in regard to their charges of conspiracy, the arrests they have made and the arrests they are still to cause to be made:

> We have been informed that as far back as July last an arrangement was made under the direction of Mr. Coffin, president of the General Electric Company, with the assistance of his right hand man, William J. Clark, by which a certain young man entered the employ of the Westinghouse Company as a draughtsman at the works in Pittsburg for the very purpose of getting into the secrets of the company for the benefit of the General Electric Company.
>
> Besides receiving a salary from the Westinghouse Company we are informed that he received a much larger salary from the General Electric Company, and a liberal fund by which he was placed in a position to be regularly furnished with blue prints and other information received from the offices and works of the Westinghouse Company.
>
> At this point a large number of the missing blue prints were located at the Lynn factory of the General Electric Company, and the Westinghouse Company served upon the General Electric Company, the Thomson-Houston Company, and several of their officials, a notice to the effect that all the blue prints were stolen property, and replevin writs for their recovery were obtained. We also gave the officials notice that if the prints were not returned to us further proceedings would be taken.
>
> Notwithstanding the great secrecy with which all these alleged deals of the General Electric Company were carried on, the Westinghouse Company believes it has complete evidence of all these facts alleged. Its evidence is supported by a large mass of original correspondence passing between the officials of the General Electric Company and parties who will be connected with the alleged conspiracy.

As a result, Morris W. Mead, Chief of the Bureau of Electricity of Pittsburg, and Frank Carey and Joseph Butler were arrested in Pittsburg, Friday afternoon, on the charge of conspiracy.

The complaint was drawn by A. S. Carpenter, counsel for the Westinghouse Company. At the same time he filed a complaint on the same grounds against Charles Coffin, president; William J. Clarke, general agent, and Milton H. Hamilton, E. N. Rice and Walter H. Knight, electricians of the General Electric Company.

A bill in equity against the General Electric Company in its corporate capacity, and also against several of the officers of the company individually, was filed on May 6 by Warren & Brandeis, of Boston, counsel for the Westinghouse Company.

The bill alleges that the defendants "have in their possession certain plans relating to electrical devices which have been wrongfully obtained from the plaintiff company, and asks that the defendants be ordered to produce them and deliver them to the plaintiff."

Mr. Coffin and Mr. Clark, for the General Electric Company, have denied these charges in toto. The latter practically admits that Westinghouse drawings have been in the possession of his company, and claims that drawings and plans are never regarded as private property.

Lieutenant S. Dana Greene, if he is correctly reported, has made the following brilliant remark on the subject: "The only point of similarity between our plans and those of the Westinghouse people is that they both provide for the use of a generator with a vertical armature. This is called for in the specifications and is, of course, common to all the plans."

The Allegheny County Grand Jury meets early in June. The case of the Westinghouse Company and the proof of conspiracy and theft will then be made public.

The American Bell Telephone Company has filed a bill in the United States Circuit Court at Pittsburg against the McKeesport Telephone Company for an alleged infringement of patent. The McKeesport company was organized a short time ago, and began business on the understanding that the Bell patents had expired. The case is a test one and will be watched with great interest by all who manipulate or patronize the telephone.

SOCIETY NEWS.

The 152d Meeting of the New York Electrical Society.

Lecture by Prof. Crocker on Dynamotors, or Direct Current Transformers.

The 152d meeting of the New York Electrical Society was held at Columbia College, Friday evening last, at which Prof. Crocker delivered an address on "Dynamotors, or Direct Current Transformers," treating successively the historical development, construction, characteristics and applications of these machines.

In his allusions to the historical development of this class of machines, the lecturer compared them with the many good inventions which fall flat upon the market in distinction to the more numerous and comparatively useless inventions which find a ready sale. He considered the dynamotor identical in principle to a dynamo and a motor acting together on any system of distribution, and thought that anyone capable of designing either a dynamo or a motor separately would be able to construct an operative dynamotor, which in its action performs the same function for a continuous current system that the transformer does in an alternating system. In this sense, such a machine was to be considered as an ordinary combination of a dynamo and a motor.

The next step in the development of the dynamotor was the combination of these two parts in a single machine having two armatures and separate fields for each. Following this an important advance, which was suggested by Gramme in 1874, although not adopted in practice until many years after, was the placing of both armature windings upon one core and the use of a single field magnet, which at once simplified the construction and added materially to the compactness of dynamotors. This disposition is characteristic of all the designs now upon the market.

One of the most important advantages offered by this arrangement is that the armature reactions found in either dynamos or motors acting separately are practically neutralized, at least to a negligible extent in this combination, and the brushes, for this reason, need no adjustment under varying loads, but act without sparking under all conditions when adjusted to their normal position, which corresponds exactly to the neutral line of the commutator. In the case of a motor the brushes, in order to work without sparking, require a backward lead, and in a generator, the demagnetizing effect of the armature coils being in the opposite direction, the brushes require a forward lead. Both of these leads in separate machines vary with the load, but in a dynamotor the two are counterbalanced, and the brushes remain normally on the neutral line under all conditions.

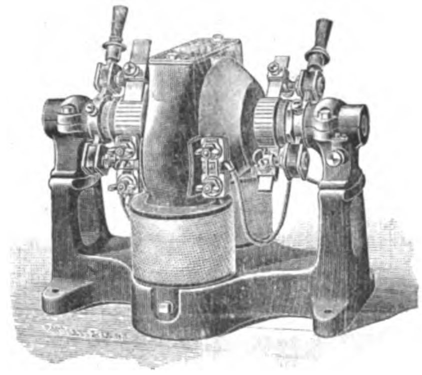
In practice it has been Prof. Crocker's experience that these machines work very successfully, and, as "the proof of the pudding is in the eating," this fact is probably the strongest indorsement of their utility. It was formerly considered impossible to use such machines for purposes corresponding to that of alternating current transformers, owing to the care which was supposed to be involved on account of the moving parts, but experience has proved that dynamotors are well adapted to take care of themselves, even when located in cellars or on inaccessible shelves, largely for the reasons that the normal position of the brushes is not shifted with changes of load, and the consequent absence of sparking, which conduces to slight wear.

The lecturer stated that there was one point in which transformers still held the lead, viz., efficiency. It is no easy task to design a dynamotor of high efficiency, especially machines of small capacity. This he considered the principal difficulty in the way of their general introduction, as their use implied two transformations of energy, each of which involves a loss. In illustration of this fact there was cited the case of two small machines of, say, one or two horse power. An efficiency of 90 per cent. in either a dynamo or a motor of this size would be considered good, and in a dynamotor, which comprises a combination of both of the former, the efficiency would be (90x90=) 81 per cent.

In the design of these machines a number of conditions arise which can only be determined by experience, such as the proportion of space to allow on the armature for both the dynamo and motor winding, the relative position of each, the most desirable density of the magnetic field, etc.

For a laboratory outfit these machines are of the greatest utility, as a number of them in connection with an ordinary electric light circuit offer almost any desired range of voltage and current, and the use of large currents, as for metallurgical work, is not accompanied by the waste due to the use of resistances where a low voltage is required.

Several machines having various ratios of transformation were exhibited in operation running on the lighting circuit of about 110 volts. In one the ratio of transformation was about 20 to 1, reducing the pressure to about six volts with a corresponding increase of current. In another the voltage was raised in the ratio of about 1 to 5, lighting five 100 volt incandescent lamps in series. An interesting machine was also exhibited which transformed the 110 volt current into an alternating current of 33 P. P. S., and in which the secondary winding was connected to two collecting rings instead of a commutator.



CROCKER-WHEELER DYNAMOTOR.

It is apparent that with direct current transformers the ratio of E. M. F. must be constant for any machine, but the ratio can be chosen at any figure. It is, of course, possible to vary the pressure by the use of resistances in either the dynamo or motor circuit, but this does not alter the actual ratio of transformation.

A dynamotor of a ratio of 1 to 1, which appears at first sight to constitute an apparently useless transformation, was alluded to by the lecturer, who pointed out the object of such a machine, especially in telegraph work. In cities of medium size there are required several voltages of various amounts for telegraph lines, many of which lines may be run from an electric lighting circuit and use about the same pressure. As the latter is supposed not to be grounded it would be impossible to connect a telegraph circuit to it without altering this condition, but by the use of a dynamotor with a 1 to 1 ratio it is perfectly feasible to run a grounded circuit from the lighting circuit without introducing grounds on the latter.

There are many applications of these machines which were alluded to besides the above, such as taking incandescent lights from a railway circuit of 500 volts or from power circuits of the same voltage which are used extensively out West. A special application of the direct-alternating transformer is in ringing bells as for telephones. In this use all that would be necessary would be to press a button and dispense with the crank altogether. While this would be a useless expense for a single instrument, in office buildings one machine could be installed which would supply current for all the telephones in the building and thus dispense with a large number of magnetos. An incidental advantage would result from being able to keep up a continuous ringing without much effort until answered.

For a system of general distribution these machines were proposed by Lane-Fox in 1883 and they include some advantages as well as disadvantages in comparison with the alternating current.

In the latter the only gain over a direct current is the ability to run at high voltages, which implies a saving of copper wire, and transform down in any desired ratio. The efficiency of the alternating current transformer is much higher than the direct current transformer, but to counterbalance this the effect of induction in the latter is avoided and its efficiency does not decrease with a reduction of load to the extent that it does with the former.

In the future development of the continuous current transformer its efficiency, according to the views of Prof. Crocker, is capable of the same improvement that has marked the development of the alternating current transformer.

The increase of three or four per cent. in the latter is a matter of the greatest care in its design and workmanship, and the same amount of refinement in the detail of the dynamotor would undoubtedly result in a proportional increase in its efficiency. In a machine exhibited which had an output of 500 watts the efficiency was about 60 per cent., which means an efficiency of approximately 78 per cent. for each part—a figure which may be considered good in either a dynamo or motor of this capacity.

A brief discussion followed the lecture in which the question of the practicability of running such transformers from constant current or arc light circuits arose. In answer Prof. Crocker stated that he had devoted considerable study to this problem, but a satisfactory solution was very difficult owing to the fact that arc light currents were only nominally constant and in practice varied from the rated ten amperes by two or three amperes in either direction. The use of dynamotors as "boosters" by running the secondary circuit in series with the primary was also discussed.

At the conclusion of the meeting a vote of thanks was unanimously tendered to Prof. Crocker, after which the annual election of officers for the society was held the following ticket being elected:

President, J. Wetzler; Vice-Presidents, Prof. F. B. Crocker, Nikola Tesla, M. M. Davis, C. E. Emery, Dr. W. E. Geyer, W. J. Jenks, C. O. Mailloux; Treasurer, H. A. Sinclair; Secretary, George H. Guy.

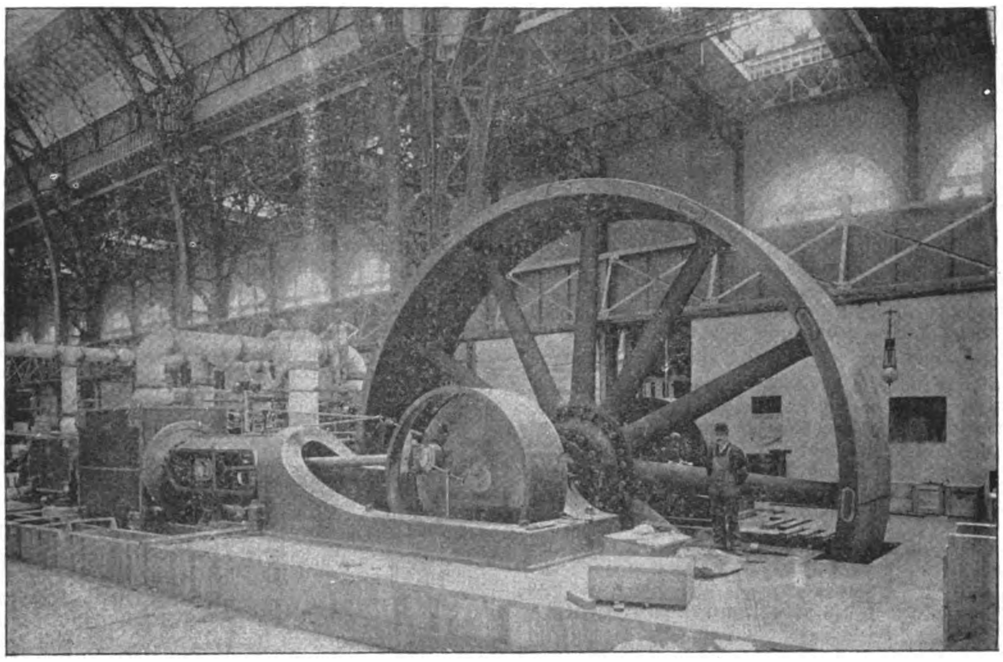
Legal Notes.

A report of the assignee of the W. D. Graves Electrical Company, filed recently in the Probate Court at Cleveland, O., shows the indebtedness of the company to be $19,446.75, distributed among 105 creditors. A majority of the stockholders were in favor of having Attorney F. B. Skeels continue in charge as assignee. Judge White reappointed him.

The attorneys of the Short Electric Railway at Atlanta, Ga., have filed an application for a receiver for the Collins Park and Belt Railroad Company. The petition shows that the defendants owe the petitioner $41,000.

World's Fair Department of Electricity.

Visitors to the Columbian Exposition in the next six months will during their tour of the buildings be attracted more by the exhibit shown in Machinery Hall than that in any of the other buildings. The size of the machines will be not the least attractive part of the display, especially those machines used in connection with the power plant. This plant occupies a space of 100 feet wide by 1,000 feet long, and is situated on the south side of the building. Most of the engines are held direct to one or more dynamos. Of all the engines which run to furnish the 5,000 horse power the one exhibited by the E. P. Allis Company is the most interesting, not only on account of its size, but also its construction. It is of the quadruple expansion type, having the four cylinders of the following diameters: 26, 40, 60 and 70 inches with a 72-inch stroke. The fly-wheel is built exceptionally heavy to make up for the diameter, it being only 32 feet across with a 62-inch face. The valve gear is of the Corliss type with a break wheel and handle attachment for starting. This engine, which is illustrated in Fig. 1, was the one which formally opened the Exposition when President Cleveland pressed the button and sent a current through the electric valve.



CORLISS ENGINE—WORLD'S FAIR. (FIG. 1.)

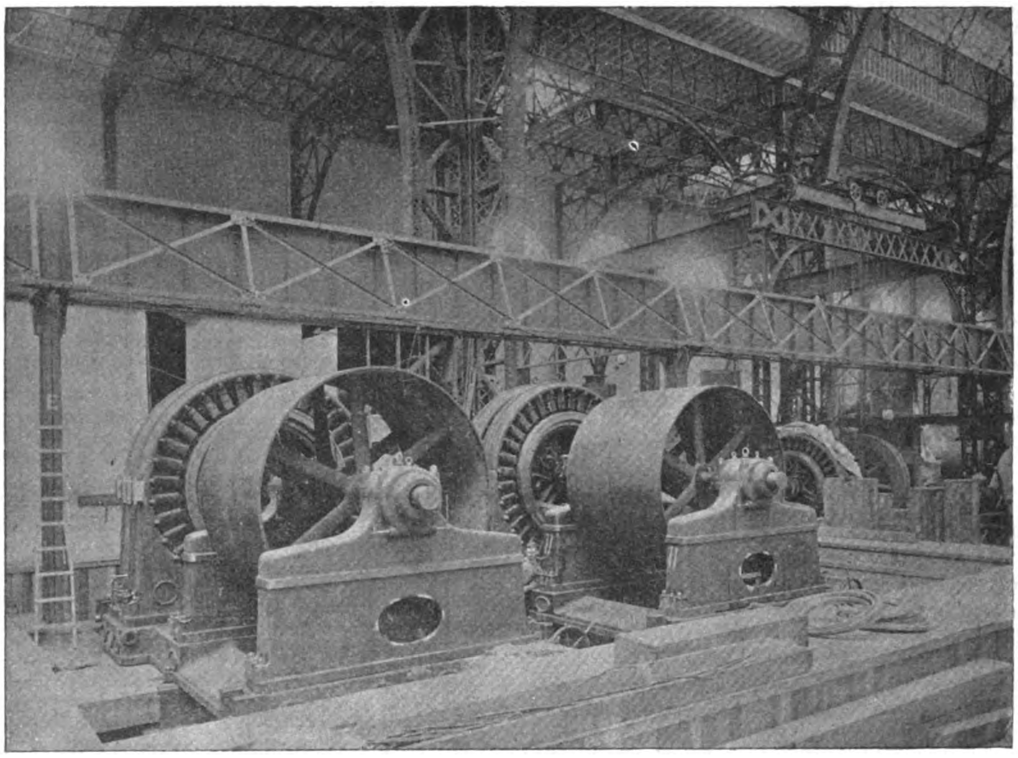
The two Westinghouse dynamos, shown in Fig. 2, and which have been fully described before, are to be belted in tandem direct to the large engine just described. The combined plant will undoubtedly represent the largest of its kind in the world.

Boston Notes.

Brookline, the most wealthy and aristocratic suburb of Boston, has not yet been pervaded by the electric street-railway system, being content to regard horse cars as more than a set off against the introduction of the overhead trolley system which the plutocrats generally don't admire. The West End Railroad Company, however, is contemplating the electrical equipment of that section of its road, and this fact has stirred up some of the daily papers to suggest to the Brookline selectmen to insist on the West End Company making elaborate tests and trials of the storage battery system before it erects the overhead system; and in view of a most important victory gained last Thursday in the State Legislature by a storage battery railway company such suggestion may have to be acted upon.

The bill to authorize the Natick Street Railway Company to extend its tracks, increase its capital stock and purchase other corporations has been passed to be engrossed by the Massachusetts State Legislature.

The two electrical topics engaging most attention in and around Boston this week have been the tremendous fall in General Electric stocks, which coming immediately after the publication of the Trust's first annual report showing a phenomenally profitable eight months' business —on paper—is a revelation of the suspicion with which these stocks are now regarded on all hands; the other topic has been the plucky fight in the Legislature over the bill submitted by the Storage Battery Electric Railway Company, of Cambridge. The bill was debated practically the entire week until Thursday afternoon, when it passed the House by such a clinching majority that its opponents did not even ask that the votes might be counted. This is a big victory and is believed to carry with it possibilities of great and radical changes in the sphere of electric railways.



WESTINGHOUSE GENERATORS—WORLD'S FAIR. (FIG. 2.)

The Lynn and Boston Street Railway, which has quite recently been equipped with electricity, will do a freight as well as a passenger business.

Ere long the West End Railroad Company is to make some important experiments with an apparatus designed and built for welding track rails together as they are laid in the roadbed, in place of them being secured as now with fish-plates, bolts, etc., etc. The apparatus will be operated by current taken from the overhead trolley wire. It has been successfully tried at Johnstown, Pa. Continuous rails, having no joints, will offer many advantages, including increased life of the rails, a saving in wear and tear of motors under the cars, greater comfort for passengers, less running noise caused by cars, while last but most important will be that these continuous rails will carry back the current to the dynamo, so that the leakage now so general will be obviated.

The "Novak" lamp, which was placed on the market less than a week ago, is proving a genuine bonanza for Claflin & Kimball, selling agents. As the result of their unique advertising, they are receiving orders by every mail from every part of the country. Their factory, extensive as it is, is already running full blast, and it looks as if increased facilities would have soon to be provided, so ready appears the entire country to be once more free from the Trust and its minions.

"The Law of the Conservation of Energy in its Practical Limitations" was the subject of an intensely interesting and instructive paper read by Mr. Charles P. Steinmetz before the Thomson Scientific Club in Lynn on Thursday evening.

A new arc lamp is under construction in Boston which is said to be, after many exhaustive tests, no less than 77 per cent. more efficient with the same current than any other lamp now on the market.

Mr. Walter Badger, who has just completed the expert course at the General Electric Company's factory, Lynn, has accepted the appointment of Assistant Superintendent of the Electric Street Railway in Rio Janeiro, Brazil, and sailed for that city last Saturday from New York. Mr. Badger enjoyed a wide circle of acquaintance in Lynn and Boston, and takes with him abundance of good wishes for his future success.

Mr. J. K. Brydes, who for several years has been superintendent of the central station at East Weymouth, Mass., has resigned that position to accept the appointment of Inspector of Central Stations for the General Electric Company.

Chicago Notes.

Harry Bishop, Western representative of the Massachusetts Chemical Company, has gone East on a visit for a week.

I. A. Gorman, Superintendent of the Richmond City Railway, Richmond, Ind., was in the city last week.

Mr. James H. Dean, of St. Paul, has joined the force of Taylor, Goodhue & Ames as traveling salesman.

Mr. E. H. Heinrich, of the Westinghouse Electric Company, made Chicago his headquarters for the past week.

Mr. H. A. Foster, formerly with the electrical division of the Census Bureau, has joined the staff of *Electrical Industries* as associate editor.

A fly-wheel on an engine in the Chicago Illuminating Company's works on Indiana ave. burst while running, and almost destroyed the station. Parts of the wheel flew into the armature of a T. & H. dynamo, and ruined the machine.

Mr. H. Cochrane, late of Denver, is in the city in the interest of the Perret Motor Company. Mr. Cochrane will have charge of the exhibit at the Fair for his company.

General News.

What is Going on in the Electrical World.

Alexandria, Va.—A new electric railway line is being laid out between this city and Washington.

McKeesport, Pa.—The electric light plant put in to replace that destroyed by fire a few weeks ago is now ready for business.

New Britain, Conn.—The Electric Light Company are having two new factories built, the combined cost of which will be $30,000.

Great Neck, L. I., N. Y.—An electric railway from this place to the steamboat landing on the Sound is a local project that is meeting with favor.

New Orleans.—The work of converting the old lines of the New Orleans City and Lake Railroad into electric roads will be begun without delay.

Muskegon, Mich.—Surveys have been made and the right of way secured for an electric railway from this city to Hackley Park Assembly grounds.

Hannibal, Mo.—A fund has been raised for a preliminary survey of a route for an electric road between Hannibal and Palmyra, a distance of twenty miles.

Norwalk, Ohio.—The Sandusky, Milan and Huron Electric Railway has given a mortgage for $100,000, covering all its property, to the Marine Bank of Cleveland.

St. Catharines, Can.—The St. Catharines and Merritton Street Railway, said to be the first electric road operated on this continent, is being extended to Thorold.

Columbia, S. C.—The electric railway is completed and cars are running to the delight of the citizens, who have been anxiously waiting to see the trolley in operation.

Terre Haute, Ind.—A sale of the property of the Electric Street Railway Company to Eastern capitalists is being negotiated. The purchase price is said to be $500,000.

Maumee, Ohio.—T. P. Brown has been granted a franchise by the town council for the construction, maintenance and operation of an electric street railway in this town.

Harrison, Ohio.—A Boston syndicate are said to be formulating plans for an electric road between this city and Cincinnati to compete with the Harrison branch of the Big Four.

Millvale, Pa.—An ordinance for the issue of $80,000 bonds to construct electric light and water plants has been introduced in the councils. It is claimed the private companies charge too much.

Fayetteville, N. Y.—A line of electric railway from Syracuse to this town is projected, and the road may be extended to Manlius. E. W. Emmons, representing the New York Electrical Works, is promoting the scheme.

Indianapolis, Ind.—The Citizens' Street Railway Company seems determined to throw every obstacle in the way of the new company and is laying track on every highway that is likely to be desirable ground for the new company.

Reading, Pa.—The directors of the East Reading Electric Railway have leased the road to the Reading Traction Company for ninety-nine years, and the cars and other property of the company have been transferred to the Traction Company.

Staten Island, N. Y.—Owing to the embarrassment of Erastus Wyman, work on the electric power plant at Livingston has been suspended and the workmen discharged. The plant will probably be completed under new management.

Cincinnati, O.—L. W. Davis, the superintendent of the Cincinnati Edison Electric Company, was found guilty by Judge Gregg of attempting to coerce employees into severing their connection with labor unions, and was fined $100 and costs.

Halifax, N. S.—The Automatic Telephone and Electric Company of Canada, incorporated by the Dominion Parliament, proposes to run a copper metallic trunk line from Halifax to Vancouver, over 3,500 miles long. Local plants will be established in towns en route.

Jersey City, N. J.—All the old cable machinery of the North Hudson County Railroad has been removed, and preparations are making for the erection of a power house on the old site to be equipped with electrical machinery of large dimensions and most approved type.

Charleston, S. C.—The city council has granted a franchise to the Enterprise Street Railway Company to construct an electric railway system throughout the city. The Enterprise Railway property was recently purchased by the Great Western Manufacturing Company of Chicago.

Shelbyville, Ind.—Representatives of a New York syndicate have contracted with the Shelbyville Electric Street Railway Company to put in a complete line and have the same in operation by August 1. The company has reorganized with Judge Hord as president, Ed Major secretary and Scott Ray treasurer.

Spokane, Wash.—A new enterprise is receiving the careful attention of several Spokane capitalists. It is the fitting up of a great health resort and summer pleasure grounds within a short distance of the city, and the building of an electric line from Spokane to the Four Lakes, ten miles southwest of the city.

Ilion, N. Y.—A corps of engineers have lately been engaged in surveying a route in this village, and from here to Mohawk and thence to Herkimer for the proposed electric road. It is understood that the Herkimer and Mohawk Company is at the bottom of the scheme, and that it is proposed to run the cars through certain streets of the village of Herkimer, forming a belt.

West Orange, N. J.—The township committee has granted an electric franchise to the Suburban Traction Company, the only stipulation being that the company should pay the township $50 a mile each year for all tracks operated in the township for the first five years, and thereafter at the rate of $100 a mile each year.

Middletown, Conn.—A meeting of the directors of the New York and Boston Inland Railroad Company is to be held here to-day (10th) to discuss the construction of a proposed electric line between New York and Boston on the Boynton system, in which a single rail only is used. Engineer Franklin Mead, of Boston, is the promoter of the plan.

Gas City, Ind.—A contract has been closed by which the American Electrical Supply Company of Indianapolis will remove its manufactory to this place. The concern will erect brick buildings covering two acres of ground and will employ over one hundred men. By the terms of the agreement the new works must be in operation by August 1.

Brooklyn, N. Y.—The linemen employed by the Citizens' Electric Light Company of Brooklyn have struck for an increase of wages from $2.50 to $3.00 a day. The New York and New Jersey Telephone Company's men are also on strike.—The strike on the DeKalb Avenue Railroad line has ended, the demands of the men for $3 a day having been granted by the company.

Geneva. Ill.—At a late meeting of the Board of Supervisors, a franchise was granted the Aurora Street Railway Company to extend its line along the highway from Aurora to Batavia, the ultimate object being to reach the county seat. A petition for a franchise for another line, to be known as the Elgin, St. Charles and Geneva Electric Railway, to extend from Elgin to the county seat, is also before the board, and will undoubtedly be passed.

Hartford, Conn.—The House passed the electric railway bill on Wednesday after making important changes in it. It now goes back to the Senate. Sections 7 and 8, which prohibit the carrying of freight and put a practical prohibition on the building of a line parallel to a steam road, were struck out by a large majority. Other important amendments were adopted which make the bill a very different measure from that passed by the Senate. It is doubtful whether the Senate will agree to the House amendments.

Salem, Ohio.—The Salem-Canton Electric Company have been discussing an electric railway project of large proportions. The scheme is to unite Massillon, Canton, Alliance, Salem and Youngstown, and the plan proposed is to obtain franchises on the right of way along the route, get all the railway companies operating electric plants in towns mentioned above to combine and extend their lines until they are finally absorbed into one gigantic system. The other towns which the road will touch are Louisville, Damascus and Canfield. Negotiations are pending to purchase the Davis electric light plant in Youngstown, and the deal will probably be consummated. This will give the syndicate control of the Salem electric road.

Chicago.—The wiremen in the employ of a number of electrical companies have quit work, having been called out by the men of the Chicago Edison Company's Works, who have been on strike for some time. Several firms, having signed the agreement not to employ non-union men, are not affected by the strike, and their men remain at work. Among these firms are the "C. & C." Motor Company, the McFell Company, the West Side Electrical Construction Company, the McEntee Company, the Cornish Electrical Company, the Heine & Fuller Company, the West Side Construction Company and the Illinois Construction Company.

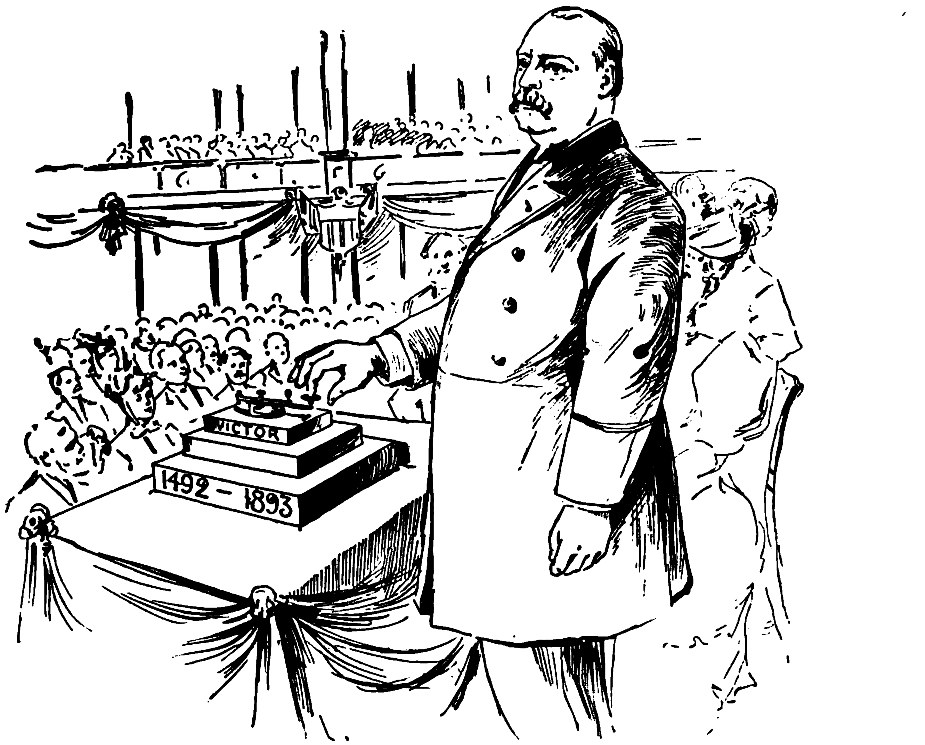
Syracuse, N. Y.—It is rumored that a company is about to be organized here for the operation of telephone plants by a new system, the invention of Syracuse men. The capital stock of the company will be $2,500,000 or $5,000,000. The object of the invention is to present an automatic telephone system whereby each subscriber can call and talk with any other subscriber without the intervention of the central office to make the necessary connection. It is simply necessary to move the indicator of the call to the desired subscriber's number, depress the call lever, when the bell at the desired station immediately responds, thus signaling the subscriber to his telephone. The men said to be interested in the enterprise are Charles M. Warner, Hendrick S. Holden, Edward A. Powell, William Nottingham, George M. Barnes, Anthony Lamb, George W. Hey and Arthur E. Parsons.

Opening the Great Fair.

A highly interesting, not to say important, incident in the ceremonies at the opening of the Columbian Exposition at Chicago was the touching of the key which closed the electrical circuit and set all the enginery of the great Fair in motion. As the supreme moment approached the eyes of the countless multitude were fixed on the little instrument that, as it were, held the machinery in leash, and as President Cleveland, pausing in his speech, raised his hand and placed his finger on the key there was a momentary hush of expectancy which was broken by tumultuous cheers as the pressure of the finger was applied and the vast and complex aggregation of mechanical apparatus became imbued with life. The scene as the President stepped forward is graphically portrayed in the illustration given herewith.

The instrument used on the occasion, clearly outlined in the picture, was the Victor Telegraph Key—in this instance made of gold although ordinarily composed of steel. It is needless to say that it performed its function in the proceedings as perfectly as science and art conduce to

perfection, and awakened admiration for the splendid electrical engineering by which such a vast and promiscuous array of machinery could be put into spontaneous action through its operation.



PRESIDENT CLEVELAND OPENING THE WORLD'S FAIR.

The " Victor" telegraph key, which gained historical significance by its employment on so memorable an occasion, will be on exhibition in Chicago at the headquarters of its makers. The E. S. Greeley & Company, Floor 1, Section F, Space 8, Electricity Building, where the company have also a large and elaborate electric and railway exhibit.

Pleased as this company must have been at the selection and success of their telegraph key they had an additional reason for feeling gratified in the effective work of another of their productions on the same occasion. Conjointly with the key which executed its task so successfully, the Greeley Exeter Dry Battery is entitled to due credit for its share in the " opening " performances. From four cells of this battery was derived the initial electric current that was employed upon the circuit which was closed by President Cleveland touching the key. The electromotive force of this cell was 1.5 volts and the amperage 8; size (cylinder) 6 × $2\frac{1}{2}$ inches. A cut of the battery is given above.

DIRECTIONS. ATTACH THE WIRES TO THE TERMINALS AND ALL IS READY.
KEEP DRY & COOL AND NOTHING WILL BE FOUND TO BEAT IT.
The E.S. Greeley & Co.

Queen & Company at the World's Fair.

An Elaborate Exhibit.

We have received from Philadelphia an attractive pamphlet, " Some Features of the World's Columbian Exposition," issued by Queen & Company, Incorporated, from a perusal of which it is evident that the exhibits of this concern cannot fail to prove of interest to all who appreciate high grade apparatus. electrical and otherwise.

To the readers of ELECTRICITY the name of " Queen ' at once suggests electrical testing instruments, and it may surprise some to learn that while a large department is devoted to such apparatus, it is only one of several others which embrace scientific appliances of almost every description.

Five separate exhibits are made necessary to properly exploit these various branches—one in the Electricity Building and four in the Liberal Arts Building.

Queen & Company will be glad to mail a copy of the above pamphlet to intending visitors, who will find it of much assistance, containing as it does general information regarding Chicago and the Fair and exact particulars as to the location and character of each of their exhibits. Application should be made at once as the supply is limited.

The Commercial Electric Company.

This company has appointed the following well-known supply houses agents for their goods:

The E. G. Bernard Company, Hall Building, Troy, N. Y.; F. A. Swan, 194 Summer street, Boston, Mass.; the W. D. Graves Manufacturing Company, 8 Case Place, Cleveland, Ohio; Jones Bros. Electric Company, 30 Court street, Cincinnati, Ohio; Bissell & Dodge, 518 Summit street, Toledo, Ohio; Commercial Electric Company, 55 Gratiot avenue, Detroit, Mich.; Southern Engineering Company, 238 Fifth street, Louisville, Ky.; F. L. Wolfrum, 455 Rookery, Chicago, Ill.; E. G. Bruckman, Equitable Building, St. Louis, Mo.

The products of the company, although on the market for a few months only, have met with a wide sale, and have already established for themselves a solid reputation.

The "Premier Products."

The electrical specialties offered to the public by Mr. M. R. Rodrigues, No. 17-19 Whipple street, Brooklyn, are worthy the attention of all who are using, or contemplate using, electricity in the operation of apparatus needing small power. For fans, sewing machines, and the like, the Premier Motors, Dynamos and Batteries are especially to be commended as embodying all the latest improvements and constructed with a view to the best practical results. The No. 1 Premier Motor. made on improved model and of neat design, starts immediately when current is applied and will run on one cell of the Premier Grenet Battery. It can be used for driving small machinery, and is well adapted for the use of students and amateur electricians. A four inch fan is provided for this motor. The new brush holder designed for use with the Premier motors enables the user to govern the pressure without the use of screwdrivers or pincers and can be raised and cleaned and the commutator cleansed without the slightest trouble.

The Premier Outfits are so well known that to mention them is simply to evoke the good estimation in which they are held by all who have made use of them, and those who need any of the apparatus or material supplied by this house need have no misgivings about the quality of the articles purchased. The stock comprises dynamos, motors, batteries, cells, fans, wire, castings (rough or finished), zinc, bluestone, lamps of various kinds, telegraph instruments and everything kept on hand in a specialty supply house.

Imported Carbons.

The General Incandescent Arc Light Company (S Bergmann president) has taken the agency for the United States and Canada for the arc light carbons and carbon brushes manufactured by Fabrik Elektrischer Beleuchtungskohlen in Nurnberg, Actiensgesellschaft vormals Ch. Schmelzer. The electric lighting public will hence have an opportunity to purchase the very best grade of imported carbons at prices which compare favorably even with domestic carbons. It is well known that the Europeans have beaten us on the quality of carbons, but their high price has heretofore kept them out of the market here. Sold in competition with American goods they are sure to be well received.

Washburn & Moen.

Washburn & Moen Manufacturing Company, Worcester, Mass., report an enormous business in their Insulated Wire Department. They have recently secured some of the largest railroad contracts.

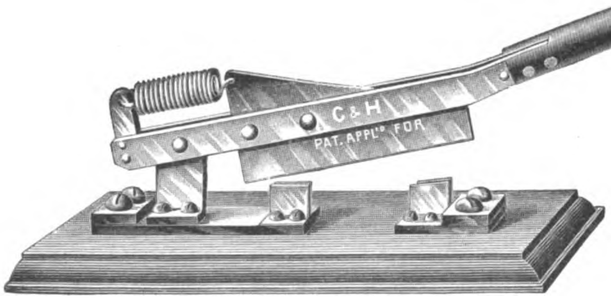
The company announce that they will soon locate in a large and commodious factory at their South Works. This factory will be equipped with most modern machinery.

It is their intention to produce nothing but exceptionally high grade wire. The large number of orders which they are daily in receipt of plainly shows the trade appreciate their high grade goods.

The rapid progress of this department clearly demonstrates the push and energy of the corporation.

The C. & H. Snap Knife Switch.

The C. & H. switch, which is herewith illustrated, is designed to meet the demand for a good knife snap switch, that will have a positive quick break action without too much complication and consequent expense. The length of the break is greater than any other switch on the market, making it especially desirable for high tension circuits. The design is extremely simple, taking and new. They are made dipped and polished, single, double or triple pole, mounted on wood or slate bases, in a great variety of styles and capacities from 15 to 1,000 amperes. The switch is designed and patented by Mr. H. H. Cutler, and is manufactured by the firm of Cutler & Hammer, 313 Canal street, Chicago.



THE C. & H. SNAP KNIFE SWITCH.

"C. & C." Co.'s Philadelphia Branch.

The following announcement is made by Mr. G. H. S. Young, of Philadelphia:

> I beg to advise you that I have severed my connection with the Pennsylvania General Electric Company, 509 Arch Street, this city, taking effect May 1st, and am now located at the address of the " C. & C." Electric Motor Company, No. 43 N. Seventh street, where I shall be glad to hear from you whenever you are in the market for electrical apparatus, or have information concerning prospective buyers. We are in a position to furnish motors and dynamos in any size from $\frac{1}{8}$ H. P. to and including 100 H. P., also to contract for isolated lighting and transmission power plants in part or whole. Thanking you for past favors and asking a continuance thereof, assuring you that any information will be fully appreciated, I am,
>
> Respectfully yours,
>
> G. H. S. YOUNG.

Micanite.

The Mica Insulator Company, 218 Water street, New York City, report increased sales for their perfect micanite insulators.

Besides the leading electrical manufacturers here and abroad who have adopted this improved method of handling mica, it is being used by the largest electrical street railway companies for repairing their motors and generators. Mica as an insulator is acknowledged by leading electricians to be equal, if not superior, to any insulating material now on the market. The advantage is seen at a glance, when one can purchase micanite insulators in any form ready to be placed in the machine without loss of time or material. Taking into consideration the great saving in cost over using mica in the regular sheet form, it will certainly pay any one wishing the best insulator to investigate micanite.

Howson & Howson.

The above firm announce that Mr. Robert T. Frazier has been appointed Manager of their Washington office, which has now been moved to the National Union Building, 918 F Street. Mr. Frazier is a graduate of the Naval Academy at Annapolis, and has had an experience of five years as Examiner in the Patent Office, having at the time he resigned from the Bureau to take charge of the Washington office of Howson & Howson, earned his promotion to the position of a Principal Examiner.

The New Sunbeam Lamp.

The trade have begun to show their appreciation of the enterprise exhibited by the Star Electric Lamp Company of Chicago in getting their new lamp ready for market so promptly. Orders are already beginning to come in in a way that is encouraging to them, and the outlook for the new lamp is very satisfactory. Those that have been sent out are proving all that has been claimed for them, and the company feel that they have made a great hit.

The Columbia Lamp Company.

The Columbia Lamp Company of St. Louis are now in full blast, with factory running full time.

The popularity of the Columbia lamps has been proven again by the influx of orders. The company deserves full success and has really laid the trade at large under obligations to it by its winning fight against the Trust.

New York Insulated Wire Company.

The above company, best known to fame through its justly celebrated Grimshaw wires, has just issued a neat little handbook containing full information as to the company's various products and a number of valuable tables of a practical nature, such as wiremen and engineers need to refer to almost constantly. Copies will be sent free to the trade by addressing the company, 15 Cortlandt street, New York.

On Deck Again.

The Buckeye Electric Company, of Cleveland, Ohio, makers of the Buckeye lamps, are again open for business, and are ready to fill orders promptly. Buckeye lamps need no endorsement, and the announcement that they are again on the market will give pleasure to many consumers.

COMMERCIAL PARAGRAPHS.

Another week of large sales of Shield Brand Moisture-Proof is reported by the Ansonia Electric Company, formerly the Electrical Supply Company.

George Cutter is supplying the Morris Poletops for the new electric railway at Syracuse, the first order being for over four hundred.

The Redding Electric Company, 41 Federal street, Boston, have issued their April catalogue, giving full information in regard to the well-known Iona specialties.

The International Trading and Electric Company have removed from the offices formerly occupied in the *Times* Building to larger quarters at 40 Cortlandt street, where they will have greater facilities for handling an increasing export electrical business.

We would call attention to the change of advertisement of the Star Electric Lamp Company in this issue. This company is now prepared to fill all orders in any quantity promptly.

The full page advertisement which appears in another part of this issue, showing eleven different types of electric gas lighting devices which are manufactured exclusively by the Electric Gas Lighting Company, Boston, forms the complete set of these devices in existence. This company owns all the patents on these devices and for years has been making and selling them by tens of thousands. To-day a practical monopoly of this branch of the electrical business is enjoyed by the same corporation and the amount of business being done is enormous.

INCORPORATIONS.

The Southwestern Telephone Company has filed articles of incorporation to operate in La Plata County, Col., with a capital stock of $25 000. Directors: J. E. Schutt, G. W. Larimer, A. R. Lewis, H. C. Fancher and J. M. Morgan.

Articles of incorporation of the Pecos Company, with a capital stock of $5,000.000, have been filed in the office of the Secretary of State of New Jersey. The purpose of the company is to aid and promote enterprises for the development and exploration of the agricultural, mineral, landed, or other resources, natural or artificial, in the valley of the Pecos River in New Mexico and Texas. The company will equip railways, telegraph, telephone, electric, gas and water lines. The principal office in New Jersey will be in Jersey City, while the main office will be in Colorado Springs. The incorporators are James A. Hagaman, Thomas H. Edsall, of Colorado Springs, and Charles A. Otis and Richard J. Boths, of New York.

The Pittsburg, Greenburg and Latrobe Electric Railroad Company, of Pittsburg, Pa. Capital stock, $1,000.000. The officers are: J. L. Mitchell, president; James H. Thomson, G. L. Owens, A. A. Stevens, John N. Givin, all of Tyrone, Pa.

The South Jersey Traction Company, Bridgeton, N. J. Capital stock, $400,000. Incorporators: George Wood and Richard W. Clay, of Philadelphia; and Walter H. Bacon, of Bridgeton. Mr. Wood has been elected president. Mr. Clay vice-president, Mr. Bacon secretary and treasurer. The company has contracted for the purchase of the property and franchise of the Bridgeton Rapid Transit Company and the Bridgeton and Millville Turnpike Company, and will succeed them in establishing trolley railways in Bridgeton and along the turnpike to Millville.

The Northwestern Water and Light Company, Lemars, Iowa. Capital stock, $200,000. President, J. H. Winchel; vice-president, Dr. M. W. Richey; secretary and treasurer, J. K. Alline. The new company will acquire the title to the water and light plant now owned and operated by J. H. Winchel, which has been constructed at a cost of $150,000, and will extend its facilities to meet the requirements of Lemars. The new company will also build, equip and operate similar plants in other towns and cities.

The Independence and Salem Railroad Company, Independence, Ore. Capital stock, $100,000. Incorporators: J. A. Veness, J. M. Vanduyn, George A. Smith, J. M. Starke and R. D. Cooper. The purpose of the company is building of a railroad from Independence to a point on the west bank of the Willamette River opposite Salem.

The Crouch Electric Supply Company, of Portland, Ore., for the purpose of manufacturing electrical supplies Capital stock, $100.000. Incorporators: Samuel L. Lovell, Edmond C. Giltner and Harry J. Singleton.

A charter has been granted for a new electric railway which will connect Chester, Pa., with Media, and the busy manufacturing towns of the Chester Creek valley. The officers of the new company are John B. Robinson, president; Edmund Jones, secretary; Edward A. Price, treasurer, and Wm. Ward, solicitor.

The Electric Railroad Company, Auburn, N. Y. Capital stock, $50,000. Directors: Charles E. Eddy, Frederic E. Storke, Frank B. Bemis, Arthur L. Sweetzer, Arthur F. Eastabrook, George Underwood, Edward B. Martin, Edward F. Allen, Alexander Beal.

The Winchester Electric Light Company, Winchester, Ill. Capital stock, $14,000. Incorporators: William Hinsfurther, Solomon Hinsfurther, William Milhous, Charles H. Condit, William Neat.

The Franklin, Bridesburg and East Fairmount Park Railway Company, Philadelphia. Capital stock, $78,000. President, George W. Ruck. It will be an electric railway.

The Huntington Electric Light Company, of Huntington, Suffolk County, N. Y. Capital stock, $20.000. Directors: Walter Lindsay, A. B. Gildersleeve, F. C. Hill and others, of Huntington.

The Chicago Electric Transit Company, Chicago. Capital stock, $500,000. Incorporators: John Casselman, Henry Wulff and Alonzo H. Hill.

The Ossining Electric Railway Company, at Albany, N. Y. Capital stock, $50,000. Directors; John V. Cockcroft, Hiram McGonegal, S. R. Stone, J. P. Truesdall and others, of Sing Sing, N. Y. The company will construct a street railroad from Sing Sing to Sparta, Westchester County, N. Y.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MAY 2, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

496,533. Electric-Distribution System for Railways. Nelson W. Perry, Cincinnati, Ohio, assignor of one-fourth to Thomas T. Gaff, same place. Filed May 27, 1891.

496,550. Electric Locomotive. Eben M. Boynton, West Newbury, Mass. Filed Dec. 7, 1891.

496,631. Double-Pole Trolley. Thomas E. Adams, Cleveland, Ohio, assignor to the Brush Electric Company. Filed June 11, 1889.

ELECTRIC LIGHTS AND APPLIANCES.

496,409. Electric-Arc Lamp. Fritz Hansen, Leipsic-Reudnitz, Germany. Filed Dec. 13, 1892.

496,455. Electric-Lighting System. Elihu Thomson and Edwin W. Rice, Jr., Lynn, Mass., assignors to the Thomson-Houston Electric Company of Connecticut. Filed April 14, 1884.

496,474. Electric Bunch-Light. Joseph Dillon, Larchmont, N. Y. Filed June 22, 1892.

496,701. Electrode for Arc Lamps. John F. Sanders and Sarah J. Sanders, Portland, Oreg. Filed June 15, 1892.

496,702. Electric-Arc Lamp. John F. Sanders and Sarah J. Sanders, Portland, Oreg. Filed June 15, 1892.

496,792. Attaching Device for Electric-Light Fixtures. George Peeples, Philadelphia, Pa., assignor to the Thackara Manufacturing Company of Pennsylvania. Filed Nov. 19, 1892.

DYNAMOS AND MOTORS.

496,449. Perforated Pole-Piece for Dynamo-Electric Machines. Charles E. Scribner and Ernest P. Warner, Chicago, Ill., assignors to the Western Electric Company, same place. Filed Feb. 7, 1890

496,456. Commutator for Dynamo-Electric Machines. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Dec. 2, 1891.

496,514. Armature for Dynamo-Electric Machines. Waldemar Fritsche, Berlin, Germany. Filed Dec. 2, 1892.

496,522. Controlling and Equalizing Electric Motors. David Mason, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 22, 1892.

496,567. Utilizing Electric Motors for Operating Machinery. Carl Hoffmann and Ernst Richter, Berlin, Germany, assignors to Siemens & Halske, same place. Filed Nov. 7, 1892.

496,710. Friction-Coupling for Dynamos or Motors. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Dec. 10, 1891.

496,791. Armature Attachment. William D. Packard, Warren, Ohio. Filed March 25, 1892.

496,648. Magnet-Armature. Fred L. Gregory, Chicago Ill. Filed Nov. 16, 1892.

BATTERIES.

496,517. Manufacture of Electrodes for Primary or Secondary Batteries. Rudolph T. E. Hensel, Dresden, Germany. Filed June 17, 1892.

496,658. Galvanic Battery. Frank K. Irving, Brooklyn, assignor to the Franklin Electric Company, New York, N. Y. Filed Jan 27, 1892.

496,743. Element for Galvanic Batteries. Auguste L. De Meriteus, Paris, France. Filed Sept. 30, 1891.

TELEPHONE AND TELEGRAPH APPARATUS.

496,513. Vibratory Telegraphy. Stephen D. Field, Yonkers, N. Y. Filed July 30, 1892.

496,549. Printing-Telegraph Instrument. Alexander H. Wirsching, Brooklyn, N. Y. Filed June 8, 1892.

MEASURING INSTRUMENTS.

496,500. Electrical Measuring-Instrument. Edward Weston, Newark, N. J. Filed Feb. 17, 1892.

496,501. Shunt for Electrical Measuring-Instruments. Edward Weston, Newark, N. J. Filed Nov. 28, 1892.

496,678. Voltmeter. Arakelyan H. Armen, Lynn, assignor to Duncan Gillis and Thomas W. Gleason, Boston, Mass. Filed Sept. 8, 1892.

496,728. Electric Meter. Joseph Edmondson and Joseph Oulton, Bradford, England. Filed Sept. 29, 1892.

496,746. Correcting Electricity Meters. Joseph Oulton and and Joseph Edmondson, Bradford, England. Filed Sept. 28, 1892.

496,801. Electrical Testing Outfit for Cables, etc. Edward W. Stevenson, New York, N. Y., assignor to Samuel L. Fox and Edward B. Fox, Philadelphia, Pa. Filed Sept. 1, 1892.

MISCELLANEOUS.

496,427. Electrically-Operated Overhead Traveling Crane. William H. Morgan, Alliance, Ohio, assignor of three-fourths to Thomas R. Morgan Sr., Thomas R. Morgan, Jr., and John R. Morgan, same place. Filed July 22, 1891.

496,432. Magnetic Crane. William H. Morgan, Alliance, Ohio. Filed June 9, 1892.

496,433. Pillar-Crane. William H. Morgan, Alliance, Ohio. Filed June 13, 1892.

496,591. Apparatus for Making Blanks by Electricity. George D. Burton, Boston, and Edwin E. Angell, Somerville, Mass., assignors to the Electrical Forging Company of Maine. Filed Feb. 20, 1891.

496,592. Working Brass by Electricity. George D. Burton, Boston, Mass., assignor to the Electrical Forging Company of Maine. Filed Sept. 28, 1891.

496,593. Electric Forge. George D. Burton, Boston, Mass., assignor to the Electrical Forging Company of Maine. Filed April 15, 1892.

496,597. Electroplating Apparatus. Seth C. Catlin, Bloomfield, N. J., assignor to Emma F. Catlin, same place. Filed June 6, 1892.

496,594. Electric Forge. George D. Burton, Boston, and Edwin E. Angell, Somerville, Mass., assignors to the Electrical Forging Company of Maine. Filed May 3, 1892.

496,602. Electric Signaling Apparatus. Stephen D. Field, Yonkers, N. Y. Filed Jan. 23, 1893.

496,611. Automatic Safety-Switch. Adelbert E. Hutchins, Detroit, Mich. Filed Dec. 22, 1892.

496,618. Electric Gas-Lighter. David J. Quinn, Brookline, and Paul W. Hoffman, Boston, Mass., assignors to the Iona Manufacturing Company, Portland, Me. Filed June 20, 1892.

Atomic and Molecular Motions.

II.

BY A. E. DOLBEAR.

When there are bodies of any degree of magnitude moving among each other as air molecules must do, there will necessarily be more or less rotary movements caused for the same reason that vibratory movements are, for very few of the impacts would be exactly in the line of translation, so all of these movements I have described are present in all gases at all times, and a clear perception of their character and mechanical necessity will be very helpful in seeing what further phenomena will follow from such conditions. Thus, suppose one of you were to hold up a shield against which baseballs should be thrown. Each one as it struck would produce some pressure upon it, and if a great number should be thrown so that some were striking upon it all the time the one holding it would be subject to a constant pressure tending to force him backwards. The strength of this pressure would depend upon how many balls struck the shield per second, and also on their velocity; their momentum would produce a constant pressure, and this is precisely the condition in a vessel filled with a gas. If the pressure of the air be fifteen pounds per square inch, it is due to the impact of the free flying molecules that strike with sufficient force to produce that pressure. In like manner the pressure of steam upon the piston head of a steam engine is caused by the impact of great numbers of water molecules in gaseous form, and as we very well know may be as great as 200 pounds per square inch or more.

It is commonly said that the expansibility of gases is due to this repulsive force. If one applies the above mechanical considerations he will see that the term repulsion has no business there. When one throws a ball against the side of the house, and it rebounds to him, he does not think it needful to suppose a repulsion between the ball and the wall, he sees that the return is due to the elasticity and the energy of the ball. So if the air in this room could be all pumped out, and a single cubic inch of air re-admitted, every particle of it would move in the same mechanical way, striking upon each other, bounding away to others and to the walls, in every direction, so that one would in a very short time find as many molecules in a cubic foot of one part of the room as another, but there would have been nothing like repulsion that had anything to do with it. The laws of motion are quite sufficient to account for all that happens without having recourse to befogging ideas.

Suppose now that the vibratory rate of the molecules be increased—that is, suppose the amplitude of vibration to be increased, no matter how, so that each molecule needed more room for itself,—a series of such molecules, each one having a greater amplitude of motion, would have a corresponding increase in the length of the series proportional to the number of molecules and to the increase in the amplitude. We say of a body that has its length increased in such a way that it has expanded. We also know that such increase in dimensions is due to what we call heat, and on this mechanical theory one sees how it comes about if heat be the vibratory motion of the molecules; indeed it follows as a necessary consequence from such motion, and it gives one too a very definite idea of the nature of heat itself. Observe that what we are now talking about is not translatory motion or oscillatory motion, but the motion of molecules in contact with each other; so that only vibratory motions proper, due to change in form, are possible, it is not needful to consider that the centres of the molecules change their positions in any case further than to allow for the increase in the amplitude of the series of molecules. I have said molecules in contact with each other. One may occasionally run across the statement that molecules are not in contact with each other at all, and sometimes one reads that molecules are relatively as far apart as the members of the solar system are from each other, but numerous measurements lately made show plainly that the distances apart of molecules in many solids and some liquids is at most not greater than a fraction of the diameters of the molecules. In gases at common pressures and temperature, the statement is approximately true. For instance, the air molecules in this room may move two hundred times their own diameter before coming in collision with others. A distance two hundred times the diameter of the earth is 8,000 × 200 = 1,600,000 miles, nearly seven times the distance to the moon.

Expansion then, whether in gases or solids, is due simply to molecular impact, each molecule requiring more room for movement when its amplitude of vibration is increased. Moreover, it is found in practice that the energy of the molecules in a gas is proportional to their temperature when measured from what is called absolute zero, and this shows to us that temperature is to be measured by the amplitude of such vibratory movement, and that the energy of a molecule is proportional to the square of that amplitude. From this it follows that at absolute zero, where there is no vibratory motion, there is no such condition as what we call gaseous. The molecules would quietly fall to the bottom of the containing vessel like so many shot and lie still.

The chemists have found too that at very low temperatures chemical action does not take place, and they have come to the conclusion that at absolute zero, the condition where there is no temperature, that is, no vibratory motion, what is called chemical affinity does not exist, molecules have no ability to combine with each other as they do when each molecule has some vibratory rate. Now, all the various kinds of matter which we are acquainted with have to be examined and experimented with at common temperatures, that is, temperatures generally above freezing, which is four hundred and sixty degrees above the absolute zero I have mentioned, and consequently all molecules are chemically combined in one way or another. Even the gases, like oxygen, consist of molecules of two atoms chemically combined. It seems therefore highly probable that at the point of absolute zero even molecules would fall to pieces. It is hardly probable that any one will be able in any way to reduce the temperature very near to absolute zero, but means have been found to reduce it as much as four hundred degrees below the freezing point of water, so that it is possible to liquefy all gases, even the air, and bring all chemical action nearly to a stand still. Such considerations give us an unexpected and extraordinary view of the relations of some phenomena to molecular motion, for it makes plain that such conditions of matter as are called gases, liquids and solids, as well as those minuter cohesions due to what has been called chemical affinity, are in the last analysis dependent upon the vibratory motions of the atoms. In the absence of temperature all solidity, cohesion and many of the so-called properties of matter would disappear. It gives one also the hint that not unlikely the rest of the properties may be reducible to motions of some sort.

I have already pointed out that other kinds of motion are possible, but I wish here to invite you to attend to some other results of vibratory motion which are of the highest degree of importance both in philosophy and in science. Every one knows of the existence of what is called the ether, a substance that seems to fill the whole of space. The reasons for believing in its existence are compulsory, and physicists are studying its properties, which are different from the properties of matter in many important respects. Matter as we know it exists in the form of atoms which combine in all sorts of ways. The ether appears to be not molecular or atomic in any sense but to completely fill all space. Matter possesses gravitative ability so that all matter attracts all other matter. The ether has no such property so far as we can learn. A mass of matter, big or little, cannot move among other masses of matter without hinderance—we call it friction—but a mass of matter of any size can move through the ether without apparently meeting with any resistance, at any rate with such velocities as we have been able to observe. The earth turns on its axis and a point on the equator moves a thousand miles an hour. It swings in space about the sun at the rate of about nineteen miles a second and has been going at such a rate for no one knows how long.

Astronomers tell us that the length of the year has not varied so much as a second in two thousand years. If the ether through which it is moving offered any appreciable friction to the earth, it would decrease its velocity and the length of the year would change.

Comets have been known to move in the neighborhood of the sun at the rate of four hundred miles in a second, and some in their long journeyings in their orbits are gone scores of years, but they return on time as if they had encountered no resistance. Such phenomena show how different the properties of the ether are from those of matter, so it cannot be proper to speak of the ether as matter. The term substance is perhaps more appropriate.

Nevertheless, the ether and matter are so intimately related to each other that some kinds of disturbances or motions of matter set the whole body of ether in a tumble. Although translatory motions do not appear to be able to affect it, yet the vibratory motion we call heat sets up a series of waves that travel to an indefinite distance in it. What we call light consists of waves which have their origin always in such vibratory motions of atoms and molecules, chiefly the former. The ether transmits such wave motions with the velocity of 186,000 miles per second, so that it takes about eight minutes for the light of the sun to reach the earth, but the light of some stars reaches us that are probably so distant as to require thousands of years to come to us, so what we see to-day left the star before America was discovered, Rome was founded or the Pyramids of Egypt were built. If the ether absorbed or stopped any of the wave motions thus imparted to it, it would seem as if we would not be able to see such distant stars as we can for their energy would all be fretted away in their long journey, for the amount to begin with is not very great if it originates in a vibrating atom but the one-fifty millionth of an inch in diameter. Yet the whole of this vast space must be filled with this medium, the ether, or the light could not get to us at all. This gives one something of an idea of the immensity of space.

In all probability light has been going in a similar way and at similar rate in the opposite direction, and one may follow this process as long as he pleases. He can come to no boundary to space, and no boundary to the ether, for as the ether is required to transmit light, if the latter should come to such a boundary in any direction it would be reflected back from it, in which case the whole canopy of the sky would be luminous—there would be no dark spaces.

The ether then gives us information of the existence of matter and its vibratory motion at immense distances from us. That the motion is of the kind I have described is plain for the following reasons: When one analyzes the light that comes from heated gases, it is seen that each different kind of matter gives out light of different wave lengths and colors. Hydrogen gives some red and some blue light. Sodium gives out yellow light, and so on. The waves are of definite and measurable lengths and are found to be very short, somewhere from the thirty-seven-thousandths of an inch to the sixty-thousandths of an inch. As light moves at the rate of 186,000 miles per second, an atom must vibrate as many times in a second as there are such waves in a hundred and eighty-six thousand miles. You can cipher it out at your leisure, but you will find it such a prodigious number as four hundred millions of millions for the longest we can see and much more than that for shorter waves. This is the rate of atomic vibration per second.

(To be continued.)

The Telephone in Sweden.

BY G. EMIL HESSE.

It is a peculiar fact that new discoveries are quickly adopted in some countries while the very same thing is more or less neglected in others. There is nevertheless always some reason for such a result if considered closely.

The rapid increase of the telephone in Sweden may be attributed to the great distance between the cities and the comparatively high rates charged for telegrams. When to this is added that very powerful companies were formed for the purpose of manufacturing and introducing them, and the cost to the subscriber was reduced to a minimum, the whole thing becomes very natural.

The instruments manufactured by Eriksson & Company, Stockholm, are of a superior quality both in regard to their working and outer appearance. This firm not only supplies the demand of the country, but also exports large numbers to foreign countries where they are unprotected by patent, and which Dr. Bell thought fifteen years ago were not worth while to bother with.

Bell telephones were at first imported, but they had very soon to give way to their more aggressive local competitor. In this and every other country where patent was applied for and obtained, no such competition is possible, but there is no doubt that a livelier interest and a greater appreciation would have been manifested if such competition had been allowed. The great mass of people do not as a rule take kindly to monopolies, even if the thing itself is good. The inventor, on the other hand, is entitled to the fruits of his work, but the facts are generally that the inventor gets very little and the company that controls the patent the most.

The popularity of the telephone in Sweden can be surmised from the fact that there is hardly a store or an office in Stockholm that does not have one, and this is the case almost to the same degree in the smaller towns. One may go to any of those stores and by paying 5 öre (1.5 cents) speak to almost any one and to any part of the country. A little more must be paid if the distance is very great.

There are also a good many stations and stores where telephone messages are received and sent thence in writing to those that have no instruments, in the same way as telegrams but at a much lower rate.

At first private companies built and operated the whole system, but the Government began in 1889 to take an interest in the business, which it is gradually acquiring.

Statistical data issued by the Kongl. Telegraph Styrelsen for 1891 show that the State at the end of the year owned 22,763.7 kilometers, with 235 central stations and 10,249 instruments. At the end of 1890 the total length of the State lines was 12,779.4 kilometers with 126 stations and 4,947 instruments. This shows a very substantial increase for one year, but we must not forget that it does not represent altogether new work, because the State bought in a good many private lines.

The length of the lines owned by private companies was at the end of 1891 38,000 kilometers with 400 central stations and 15,000 instruments. The length at the end of 1890 was 39,800 kilometers with 432 central stations and 15,500 instruments. This shows a falling off for the private companies for the reason already mentioned.

The total length of the lines at the end of 1891 was therefore 60,763.7 kilometers, and at the end of 1890 52,579.4 kilometers; increase, 8,184.3 kilometers. Central stations, 1891, 635, and 1890, 558; increase, 77. Instruments, 1891, 25,249, and 1890, 20,447; increase, 4,802.

The cost of the State lines was 3,703,713.31 kroner, and of that sum 1,403,110.39 kroner was expended during 1891, which goes to show that the Government only recently took the question in earnest.

The gross receipts for 1891 were 744,983 kroner, or 72.69 kroner per instrument, which is a little less than $20. The net income was 258,299 kroner, which on the capital invested means a profit of about 7 per cent.

To show the great importance of the telephone in Sweden, it is interesting to note that the total length of the telegraph lines, including about 8,000 kilometers cable, was at the end of 1891 32,264.5 kilometers. The gross receipts were 1,464,491.31 kroner and the net income 123,096.89 kroner, which compared with the profit on the telephone is very little. Few if any inventions can show such results, but it proves that it is not always wise to neglect patenting good inventions in Sweden, a thing generally done by American inventors.

Some Applications of Electricity to Chemistry.—II.*

The electrolysis of fused salts has not been studied nearly so thoroughly, either from a theoretical or practical point of view, as the aqueous solutions of the same compounds. This is partly because it is not easy to work with substances which are red or white hot. Again, many of the salts volatilize at temperatures close to their fusing points, and on the small scale necessary for laboratory work it is troublesome to regulate such temperatures with any accuracy. The electrolysis of fused salt is a tempting process. Chlorine is given off at one pole, and there is no trouble from the formation of hypochlorites. At the other pole sodium comes off in vapor. Sodium, it need hardly be mentioned, is very much more valuable than caustic soda. It is largely employed for reducing aluminium from its chloride by substitution. In addition to that, however, it would provide a means of obtaining pure caustic, as all that has to be done is to allow water to act upon it. This would mean saving in packing and carriage. Many attempts have been made to produce sodium from fused common salt on a large scale, but so far the process does not seem to have been satisfactory. Sodium is produced, but it is difficult to collect it free from salt. Then there is trouble with the anodes. The various metallic chlorides are mostly easily fusible, and so are many fluorides and cyanides. By employing their fused chlorides, strontium, magnesium, calcium, aluminium, and barium may be reduced electrically.

The chief industrial application of the electrolysis of fused salts is in the production of aluminium. One of the forms in which aluminium occurs in nature is a double fluoride of aluminium and sodium cryolite. This ore is fairly plentiful, and was for a long time employed in Germany as a source of sodium in soda manufacture. The cryolite is fused and electrolyzed in an iron vessel. This is kept hot, and the cryolite is kept in a molten state by the heat produced by the passage of an enormous current against the resistance of the electrolyte. The oxide of aluminium or alumina is in many cases dissolved in the cryolite also. Salt is frequently added to reduce the melting point, so that a lower temperature will serve.

When an electrolyte is subjected to an electric current a transference of the radicle takes place, or as it is generally put, there is a migration of the ions. If a solution of chloride of copper were electrolyzed, and if there were no movement of the chlorine and copper during electrolysis, all the chlorine in the immediate neighborhood of the anode would be used up, and the water would be called upon to give up oxygen. At the cathodes on the other hand a little copper would be produced, but as soon as the salt in contact with the electrode was exhausted hydrogen would be evolved. The result would be that with, say, a 20 per cent. solution of the salt, only a fifth of the chlorine and copper corresponding to the quantity of electricity passed would be produced, the rest being spent on decomposing the water. The solution would in fact be decomposed in the exact proportion in which it came in contact with the electrodes. This transference is made available in electrical tanning. It takes a long time to tan a thick hide, because the tanning solution penetrates the skin very slowly, on account of the cells of which it is composed being impervious. Mechanical agitation will force the liquid into the interstices of the hide, but no farther; it cannot force the liquid through the walls of the cells. The passage of electricity, however, causes the tannin to pass through the walls of the cells also. It thus comes about that mechanical agitation alone does not accelerate tanning much, and electricity alone is also of little use, for the movement of the radicles is exceedingly slow. The combination is most effective, however, as the agitation brings the liquor into contact with the cells, and the electrical action drives it through the walls. The action of electrical tanning has been investigated by Dr. Rideal and Mr. Trotter, and Mr. Falkenstein is doing further work on the same very obscure but interesting and important subject.

The osmotic theory stated above was given by the lecturer in a discussion on a paper by Messrs. Rideal and Trotter. Electric tanning on the Groth system is in commercial work in this country, and produces first-rate leather in a few hours.

A 400 K. W. ALTERNATOR.

The machine shown in our Frontispiece represents the type of alternators built by Hillairet & Huguet, of Paris, three of which have been installed in the large station in the Champs Elysées, described in *L'Industrie Electrique*. These alternators have a fixed armature, and the fields, which are mounted directly upon the engine shaft, revolve within the armature, each of which carry 80 poles. The diameter of the fields is nearly 18 feet, and a current is generated of 133 amperes at 3,000 volts, and has a frequency of about 40 periods per second.

The nominal capacity of the machine illustrated is therefore about 400 K. W., but will run up to 455 K. W. on emergency. The net efficiency guaranteed by the makers is 85 per cent. The insulation resistance of the armature is guaranteed also 50 megohms and that of the fields 100,000 ohms.

---

* Abstract from *Industries* of a lecture at the Royal Institution, delivered by Mr. James Swinburne.

The Distribution of Power by Alternate-Current Motors—II.

BY ALBION T. SNELL.*

4. MULTIPHASE ALTERNATE MOTORS.

Prof. Ferraris in 1885 experimented with multiphase currents, and published his results in March, 1888, at Turin; and in May of the same year Tesla showed a rotary motor running with four wires; and Bradley, Haselwander, Wenstrom, Elihu Thomson, Dobrowolski, Brown and others have introduced various modifications and improvements. The first practical demonstration was made by Dobrowolski and Brown with the Frankfort-Lauffen plant.

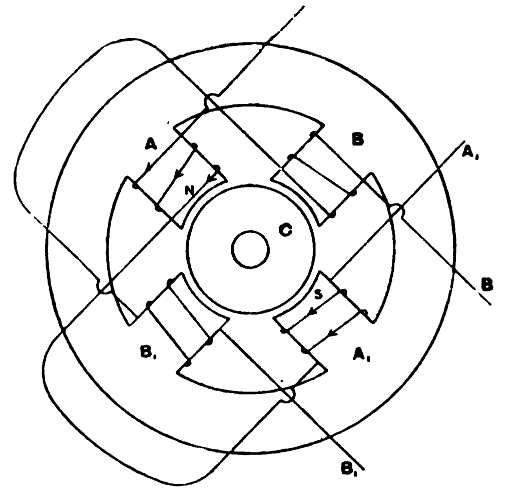

FIG. 1.

It should be noticed that in all rotary field motors and dynamos it is not the current, but the resulting magnetism, that rotates; thus, if there are two circuits and four poles, the magnetism will be displaced 90 deg. with each wave of current. In order to see this more fully, a simple case may be instanced. Fig. 1 is a four-pole diphase motor of elementary type, with a closed-circuit armature, having neither brushes nor commutator. There are two alternating exciting circuits, $A\ A_1$ and $B\ B_1$, in quadrature.

Suppose that A and A_1 be magnetized so as to cause lines of force to pass from A to A_1 through the armature C. Then B and B_1 will be neutral, for there will be no current in them at this moment.

Next, the current in $A\ A_1$ will gradually die away, and that in $B\ B_1$ will steadily rise in an equal and opposite ratio until the magnetic flux from B to B_1 and A and A_1 are neutral.

This cycle will be repeated, but with one alteration—the current in $A\ A_1$ will rise to a negative maximum (assuming it to have been positive before), and the flux will be in the direction of A_1 to A; and in the next wave from B_1 to B. Carefully noting these changes, it is seen that the magnetic field has rotated once for a complete ∿ in each of the circuits, and, therefore, the speed of the field rotation is $\frac{N}{n}$, where N is the number of ∿ per second, and n is the number of pairs of poles in one circuit. In the case referred to, since $n = 1$, the revolutions of the magnetic field will be the same as the number of ∿. To make a diphase dynamo it is necessary to replace the closed-circuit armature by a suitable electromagnet having as many free poles as there are poles in one of the alternate current circuits, to excite this magnet with a continuous current, and to cause it to revolve.*

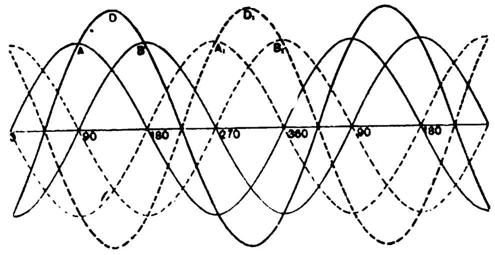

FIG. 2.

Then diphase periodic currents will be induced in the two circuits $A\ A_1$ and $B\ B_1$, the phase difference between them being 90 deg.

Mathematically the currents may be expressed thus:

That in $A\ A_1 = K \sin a$

" " $B\ B_1 = K \cos a = K \sin \left(a - \frac{\pi}{2}\right)$

which shows the phase difference between the two currents. Now, K is a constant for the particular machine and a is a measure of the angular motion of the field. It will be seen that current in $A\ A_1$ is a maximum when a is equal to $\frac{\pi}{2}$ and $\frac{3}{2}\pi$, and is zero when a is equal to O and π; the converse of this is the case with the current in $B\ B_1$.

Diphase systems require either four wires—i. e., two for each circuit—or else the common return must be of double section for the same loss. This is inconvenient on account of both cost and complexity; but a far greater objection for large plants seems to be the apparently excessive variation in the field excitation, yet this view is strongly combated by many competent engineers. Let Fig. 2 be carefully examined.

Curves A and B show the current-fluctuations in the two circuits, and D that in the common return. The magnetic field will be caused by A and B alone, and, therefore, will be proportional to their sum at any instant. When A is a maximum, B is zero, and the induction at this moment is proportional to the current in A alone, and is equal to, say, $C \sin \frac{\pi}{2} = C$. When A and B are equal, as at 135 deg. of field rotation, the induction is proportional to $2\ C \sin 135\ \text{deg.} = C\ 1.4$. Thus the excitation varies between 1 and 1.4, the difference being nearly 30 per cent. of the highest value. The mean variation will be only about 15 per cent., it is true, but hysteresis and self-induction are proportional to the limiting values of the excitation, and eddy currents approximately to the squares of these differences.

Self-induction decreases the output for a given weight of material, and also by increasing the lag may largely augment the idle current for small loads.

To illustrate the fluctuation of the field excitation and consequent induction the sign of the negative curves in Fig. 2 may be changed, and they may be plotted above the time line as if they were positive in value; or two fresh complete curves may be drawn, as shown in dotted lines and marked A_1 and B_1 in Fig. 2, referring to the next two impulses of current immediately succeeding waves A and B.

Both these diagrams are justified by the consideration that each circuit in the motor contains at least two coils wound in opposite directions, and thus produces poles of different signs; and therefore the magnetism rotates continuously.

In Fig. 3 the sign of the negative curves has been changed, and the excitation fluctuation is shown by the top curves, which may be regarded as having reference to one of the poles of the rotary field, say the north pole; while with the double arrangement shown in Fig. 2, since there are two sets of curves—one positive and the other negative—the variations of both poles are indicated. But as the fluctuations are sufficiently defined by the first method, the duplication involved in the latter seems to be unnecessary.

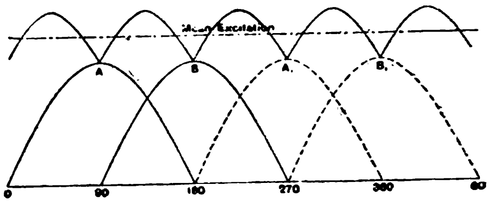

FIG. 3.

In the preceding considerations the armature reactions have been neglected. These are not easily estimated without some experimental acquaintance with the machine in question. But their effect will be a maximum at starting, and will decrease as the armature speed increases, and would be nil if the speed of armature and field coincided—i. e., if the motor worked synchronously. The last condition is unattainable even with no load, for the friction of the bearings and air requires a certain amount of current in the armature to overcome it. Generally speaking, the armature reactions tend to weaken the resultant magnetic field and also to lessen the torque for a given current.

5. TRIPHASE OR DREHSTROM CIRCUITS.

An inspection of Fig. 3 will show that in order to reduce the variation of the field magnetism it is presumably necessary to increase the number of circuits. Take four with phase differences of 45 deg. The field excitation will be nearly constant, but eight wires will probably be required; for it is doubtful whether common returns similar to the direct-current five-wire system would be practicable.

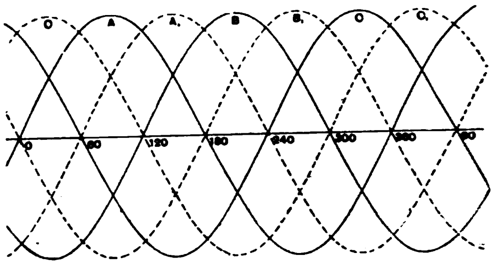

FIG. 4.—Three Periodic Currents Separated by a Phase Difference of 120 Deg.

Yet the next advance in multiphase working was made by using three circuits with currents differing by 120 deg. in phase. Since the phase difference is increased this does not seem a self-evident improvement; but on closer study it is seen that the excitation is more constant, and that the algebraic sum of the three currents is equal to zero.

In Fig. 4 let A, B and C represent three periodic currents separated by a phase difference of 120 deg.; and let the instantaneous values of the currents be severally represented by C_1, C_2, C_3. Thus:

$$C_1 = K \sin \alpha \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$C_2 = K \sin \left(\alpha - \frac{2}{3}\pi\right) \quad . \quad . \quad (2)$$

$$C_3 = K \sin \left(\alpha - \frac{4}{3}\pi\right) \quad . \quad . \quad . \quad (3)$$

And $C_1 + C_2 + C_3 = 0$ by hypothesis. For $K \left\{ \sin \alpha + \sin \left(\alpha - \frac{2}{3}\pi\right) + \sin \left(\alpha - \frac{4}{3}\pi\right) \right\} = 0$, which is easily proved to be the case.

Drehstrom working is accomplished by parallel or series coupling of the circuits, the two methods being severally known as the star and triangle systems. The author regards as the field magnet that part of the machine in which the rotary fielp

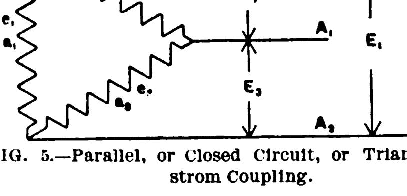

FIG. 5.—Parallel, or Closed Circuit, or Triangle Drehstrom Coupling.

---

*Paper read before the Institution of Electrical Engineers, London.

*Rotary magnetic-field machines under certain conditions are reversible. See *Electrical Review*, February 10, 1893, in which an experiment is given showing the reversibility of a "three-phaser."

is produced. In a triphase motor, then, the field magnet will be that part which receives the Drehstrom from the mains, regardless of whether it rotates or not. In the dynamo there can be no confusion, for the field magnets, in present designs at any rate, always rotate and are excited by a separate direct current. In this paper large capitals are used to distinguish the main carrying the Drehstrom, and italics to denote the three windings on the field magnets of the motor, or the armature of the dynamo. Suffixes are used to mark the phase order of the circuits. It is also assumed that the effective values of the current are read by dynamometers, and that of pressure by voltmeters of the hot-wire or electrostatic type.

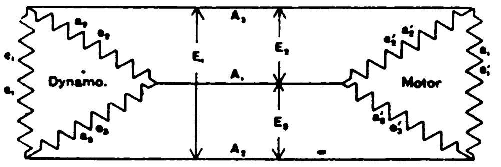

FIG. 6.—Drehstrom Dynamo Coupled to a Motor.

The parallel or closed circuit, or triangle coupling, is shown in Fig. 5. Let A_1, A_2, A_3 be the effective values of the several currents flowing in the mains, and a_1, a_2, a_3 the corresponding effective currents in the coils. Also, let E_1, E_2, E_3 be the effective pressure at the terminals of a_1, a_2, a_3. And assume $A_1 = A_2 = A_3$; then $a_1 = a_2 = a_3$, and $E_1 = E_2 = E_3$. And let there be no self-induction or capacity.

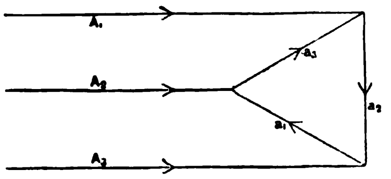

FIG. 6A.

With these assumptions, since a is in phase with e, and A lies 30 deg. removed from a, it follows, if the mains be fed with a combined three-phase current (as in Fig. 6) that the current in one main will differ in phase by 30 deg. from the pressure between it and the two other mains. This is seen to be the case from the geometrical relationship of the coils and the mains. And it can also be proved that the effective value of the current in each of the mains is equal to 1.732 times the effective current in each of the coils, when the circuits are equally loaded. In Fig. 6A let the currents in the mains and in the coils be considered positive when flowing in the direction indicated by the arrows, and let the phase and magnitude relations of these currents be represented by Fig. 6B. Then, if the diagram 6B be supposed to revolve uniformly around its center, the length of the projections of the sides of the diagram on any straight line will represent the instantaneous values of the corresponding currents; for it is plain that these projections satisfy all the necessary conditions—viz. :

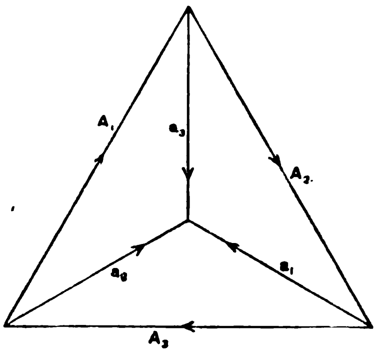

FIG. 6B.

$$\left.\begin{array}{r} A_1 = a_2 - a_3 \\ A_2 = a_3 - a_1 \\ A_3 = a_1 - a_2 \\ A_1 + A_2 + A_3 = 0 \\ a_1 + a_2 + a_3 = 0 \end{array}\right\}$$ All instantaneous values —i. e., the lengths of the projections of the corresponding sides of Fig. 6B.

Again, the sides of the diagram 6B are proportional to the effective values of the corresponding currents; and if the load be equally distributed between the three mains, then for effective values,

$A_1 + A_2 + A_3 = 0$; and $a_1 + a_2 + a_3 = 0$; and $A_1 = 2\ a_2 \sin 60$ deg.; or, generally, $A = 1.732\ a$.

The above demonstration was suggested by Dr. Sumpner.

By a similar diagram the relation between the effective pressures on the coils and mains in the open or star arrangement can be shown to be $E = 1.732\ e$. See (*b*) of this section. The relative position of the phases of currents and pressure in the mains and coils of a combined Drehstrom circuit of the closed type with no self-induction are shown in Fig. 7 (E and e have the same value and coincide in phase). It will be seen that the maxima of the currents in the mains, A, are always midway between those of the coils, a, and that the phase difference between them is 30 deg.

(*b*) The series, open circuit, or star coupling is shown in Fig. 8. As before, let there be no self-induction or capacity, and let $A_1 = A_2 = A_3$; $a_1 = a_2 = a_3$; and $E_1 = E_2 = E_3$. Now, since the mains, A, are in series with the coils, a, and there is by hypothesis no self-induction or capacity, $A_1 = a_1$, $A_2 = a_2$, and $A_3 = a_3$. But the pressures between the mains are not the same as those at the coil terminals. And e will lag 30 deg. behind E and will be numerically equal to $\frac{E}{1.732}$ or, $e = \frac{E}{2 \sin 60 \text{ deg.}}$, and therefore $E = 1.732\ e$.

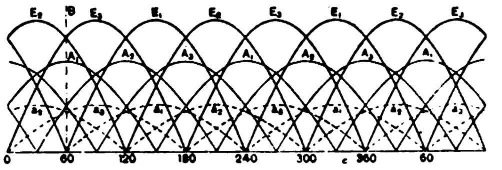

FIG. 7.—Diagram of Relative Position of Curves of Currents in Mains and Coils of a Closed-Type Combined Drehstrom Circuit with no Self-Induction or Capacity.

The phases of current and pressure in a combined Drehstrom circuit of the open type are shown in Fig. 9 (A and a have the same value and coincide in phase).

The conclusions thus arrived at are true only on the assumptions (*a*) that the coils themselves have no self-induction, and (*b*) that both the coils and the mains are equally loaded. The first condition is never found in practice, and the second is only likely to obtain with small motors, and then only in an approximate degree. The effect of self-induction is to cause the current in the coils to lag behind the pressure at the terminals. To measure exactly the power of a Drehstrom system, then, is a complicated task; but it can always be done by measuring the work performed in each of the separate circuits and adding the quantities.

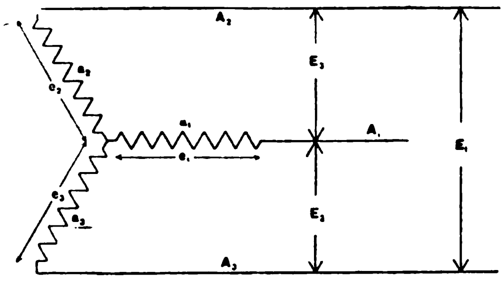

FIG. 8.—Series, or Open Circuit, or Star Drehstrom Coupling.

In Fig. 5, the energy $= 3\ a\ e = 3\ E \frac{A}{1.732} = E\ A\ 1.732$ if the three circuits be equally loaded, and there be no self-induction or capacity.

In Fig. 8, also, the energy $= 3\ a\ e = 3\ A \frac{E}{1.732} = E\ A\ 1.732$ on the same assumptions.

So it appears if there be no self-induction and an equal load in each circuit that the number of amperes in one of the mains multiplied into the pressure between two mains into 1.732 gives the power in watts. If there be self-induction, the above quantity must be multiplied by the cosine of the angle of lag between the current and the pressure. The energy absorbed by a motor, therefore, will be expressed by $E\ A\ 1.732 \cos \varphi$, where φ is the angle of lag.

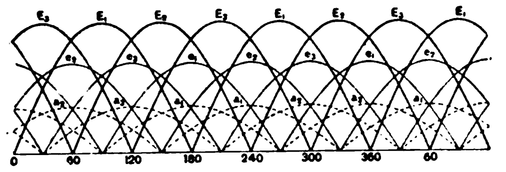

FIG. 9.—Diagram of Relative Position of Curves of Pressure and Currents in the Coils and Mains of the Open-Type Combined Drehstrom Circuit with no Self-Induction or Capacity.

If the three circuits be equally loaded, the power can be measured by one wattmeter (see Fig. 9A). Put the current coil in one of the mains, say A_2, and take two readings, one with the pressure coil coupled between A_1 and A_2, and one with it coupled between A_2 and A_3. The power will be equal to the sum of the two readings.

And if the load be unequally distributed, two wattmeters are required (see Fig. 9B). Place the current coils in two of the mains, say A_1 and A_3, and couple one pressure coil between A_1 and A_2, and the other between A_2 and A_3. The power is then the sum of the two wattmeter readings.

The author is indebted to Dr. Sumpner for the above methods of measuring the power in multiphase circuits by wattmeters. They are also applicable for reading power with direct currents.

In part (*a*) of this section it was shown that with combined three-phase currents, even when neglecting the self-induction of the coils, there is a constant phase difference between the current and the line pressure. This, although not in itself a direct loss, is the cause of great difficulty in measuring, regulating and controlling the currents, and also reduces the output for a given weight of material. Hence it has been found expedient to work the dynamo circuits unconnected, and to use six or more separate coils. The currents from these are combined by a suitable transformer so as to convert the secondary currents into a combined high tension rotary current with phase differences of 120 deg. This high pressure current is reduced at the motor end of the line by another suitable transformer, and sub-divided as required. In the transformers, says Mr. Dobrowolski, there is not the same constant difference of phase of 30 deg. (between the current and the pressure), but owing to the connections of the secondary coils the transformation ratio is not equal to that between the primary and the secondary turns, so the latter must be increased to the extent of this difference. The ratio is 2 : 1.732, or a difference of 14 per cent., neglecting all losses from other causes than the connections. The efficiency of Drehstrom transformers is probably not quite so high as that of single-phase ones, but it is not much less, and when the advantages of low pressure dynamos and motors with high pressure transformers is fully appreciated, the slight difference in efficiency appears insignificant.

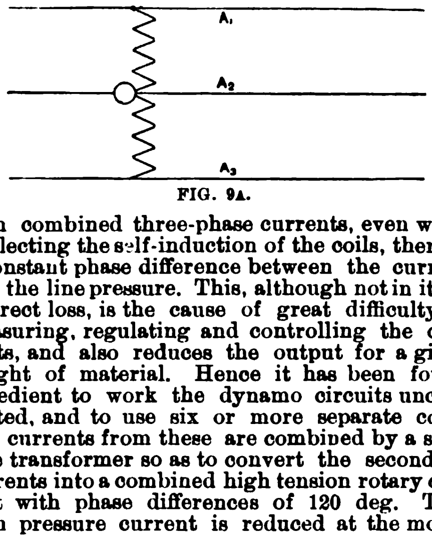

FIG. 9A.

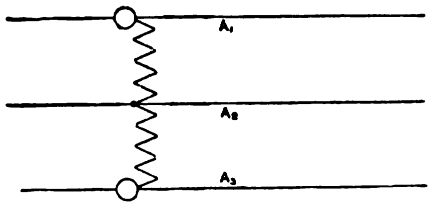

FIG. 9B.

(*To be continued.*)

Electricity In Agriculture.

The Influence of Electric Light Upon Vegetation.*

This particular phase of the question under discussion has been but comparatively little investigated. This is due to several causes. First of all, as long as electric light could only be obtained by aid of strong batteries the entailed costs were too high to render experimenting practicable. With the discovery and perfection of the dynamo-electric machines, supplying light at a relatively trifling cost, came the first satisfactory tests. Of the experiments made in recent years, those of C. W. Siemens in 1880 deserve special mention.

He first selected two electric lamps of 4,000 candle power fed by a dynamo machine, which was in turn driven by a high-pressure steam engine of 6-horse power. One of the lamps was placed in a glass house whose cubic contents were 2,318 feet; the other was placed at a height of from 12 to 14 feet over a hothouse of like size. The inside lamp was fitted with a reflector which threw the rays directly upon the plants, while the outside lamp, on the other hand, was provided with a transparent shade. The experiment began on October 23, 1880, and was continued until May 7, 1881. Sundays excepted, the light was turned on at 6 o'clock in the evening (5 o'clock during the shortest days) and kept up until daybreak. The temperature of the two houses was about 15° Celsius. A large number of vegetables and flowers were planted and observations taken. It was soon discovered that the influence of the outside light was beneficial, while the plants under the rays of the naked light showed a wilted appearance.

Suspecting that the combustible products of the light might exercise a dwarfing influence, the experimenter sought to remove this difficulty. By the help of an engine, which also pumped in currents of fresh air, clouds of steam were introduced into the hothouse between the plants and light. This device proved to be a step in the right direction, though it became eventually necessary to provide the lamp with a shade. This last served at once a double purpose, viz., it diverted the combustible products and supplied a shade between the plants and light.

In this connection it was most instructive to watch the workings of the last mentioned contrivance. If the shade was so placed as to protect only a part of the plants, the line of demarcation showed itself very plainly on the leaves—even after a single night. Those plants at a distance of from 9 to 10 feet from the naked light were distinctly wilted, while those under the shade of a thin glass presented a healthy appearance. This line of difference could even be detected on single leaves. Young stalks showed the injurious effect of naked light at a distance of 20 feet.

Here was clearly a question of the absorption of certain kinds of rays through glass. As electric light is rich in invisible, frangible rays which are capable of being mostly absorbed through shaded glass, Siemens concluded that these rays were especially destructive to the cells. To ascertain this more accurately, an experiment was undertaken. The soil of a hothouse was sown with plants of quick growth and in parcels at equal distance from the light. The first parcel was exposed to the naked light, the second was covered with thin glass, the third with yellow glass, the fourth and fifth with red and blue respectively. The growth was carefully observed daily and the following facts reported:

The plants under the thin glass showed a strong and healthy appearance. Next came the plants under the yellow glass, although the color and thickness of the stalks suffered considerably by contrast. The plants under the red glass had a feeble growth and yellow leaves, and those under the blue glass were still more sickly. Finally, the plants of the exposed parcel showed a stunted growth, with leaves very dark and partly wilted. Throughout the entire experiment care was taken to provide during the day a suffused daylight and a sufficient air circulation.

By a natural process of elimination, Siemens next turned his attention to experimenting with a lamp with a thin glass shade. He noted that peas sown at the end of October, under the influence of the electric light (discontinued, as before, on Sundays alone,) bore ripe fruit on February 16. Raspberries transplanted into the hothouse on December 16 ripened March 1; and strawberries set out at the same time bore fruit of a superior taste and color on February 14. Grapes of vines budding on December 26 ripened on March 26, but were unusually sour in taste. Wheat, barley and oats shot up with surprising rapidity, but did not ripen. After reaching the length of about 12 inches, they began to wither and die. More favorable were the results of the attempt with the same grains and the light in the open air. The sowing took place on January 6, but the germination was slow by reason of the snow and frost. With the advent of milder weather, however, a rapid growth took place, and the fruit ripened at the end of June. That plants grown under the influence of electric light bring forth fruit which can be successfully used for seed purposes was demonstrated by an experiment with peas. Peas gathered on February 16 were planted on February 18. They germinated a few days later and were healthy in appearance.

Still another interesting series of experiments was conducted by P. P. Dehérain at the time of the Electrical Exposition in Paris in 1881. The plants were grouped into five distinct sections. In the first there was electric light day and night; in the second a diffused and weak daylight, with electric light at night. The plants in the third section were in the open air, exposed to a strong natural light during the day, with electric light at night. In the fourth section there was the weak light of the Exhibition building during the day and entire darkness at night. The plants of the fifth group were in the open air and left to their normal growth.

The damaging effects of the light of about 2,000 candle power began to be clearly evident in the majority of cases at the end of seven days. This was especially true in the division having the electric light day and night. Some plants lost their leaves entirely and others had a wilted appearance. Most curious was the influence of the light upon the *Syringa vulgaris*. The leaves directly exposed turned black, while those underneath, protected by others above them, kept their fresh green color. The same phenomena were noticeable in a less marked degree with the azalias and chrysanthemums. An experiment with the blackened leaves showed that the epidermis alone had been injured. The detrimental influence of the light was more marked with the old leaves than with the young ones. In some cases new leaves immediately replaced the old ones which had fallen off, and these showed greater powers of resistance. All the plants which received the electric light during the night were in some like respect damaged, though not in so marked a manner. It was clearly shown, however, by the results in groups two and four that those plants receiving weak daylight and electric light at night were in much healthier condition than those receiving the same light during the day but left to the darkness at night.

Further, Dehérain undertook to discover to what extent the electric light decomposed carbonic acid. It was demonstrated that the light possessed this power, but in a degree much inferior to the sun. On a favorable summer day the quantity of oxygen collected in one hour equalled that gathered by the aid of the electric light in several days.

Satisfied that the direct rays exercised a harmful influence, Dehérain next experimented with shade lamps. Here, too, the plants developed unnaturally. Of a large number of varieties, barley alone ripened. The causes of this unfavorable influence were ascribed to the fact that the light was too weak to assimilate the carbon generated by the carbonic acid and too feeble to have the required effect upon transpiration.

These tests satisfied the experimenter that electric light, even under the best conditions, could be used with but relatively small returns, and this, too, only in those regions where the water power or fuel could be furnished at a very low rate. For those plants receiving a strong sunlight during the day the light might be successfully employed at night during the period of most vigorous growth, i. e., from germination to blossoming.

American Institute of Electrical Engineers.

Annual and General Meetings at New York, May 16 and 17, 1893.

The annual meeting of the Institute for the reception of the yearly reports, the election of officers, and other business proceedings will be held at the headquarters of the Institute, No. 12 West 31st street, at 4 P. M. Tuesday, May 16th. It is expected that this session will occupy about two and one-half hours.

After adjournment, those who so desire will assemble at "The Arena," 41 West 31st street, where a dinner will be served. This will be a purely social gathering, and it is hoped that all who find it convenient will endeavor to attend. Friends may be invited.

GENERAL MEETING.

MORNING SESSION.

The morning session of the general meeting for the reading and discussion of papers and reports will be called to order at 10 o'clock, Wednesday, May 17th.

The following papers will be read:

1. "On the Behavior of Fuse Metals in Direct and Alternate Current Circuits," by Mr. Charles P. Matthews, of Cornell University, Ithaca, N.Y.
2. "A Modified Deprez D'Arsonval Galvanometer," by Lieut. Charles D. Parkhurst, of Watervliet Arsenal, West Troy, N. Y.
3. "The Variation in Economy of the Steam Engine due to Variation in Load," by Prof. R.C. Carpenter, of Cornell University, Ithaca, N. Y.
4. "An Automatic Printing Speed Counter for Dynamo Shafting," by Prof. George S. Moler, of Cornell University, Ithaca, N. Y.

At 1 P. M. a recess of one hour will be taken.

AFTERNOON SESSION.

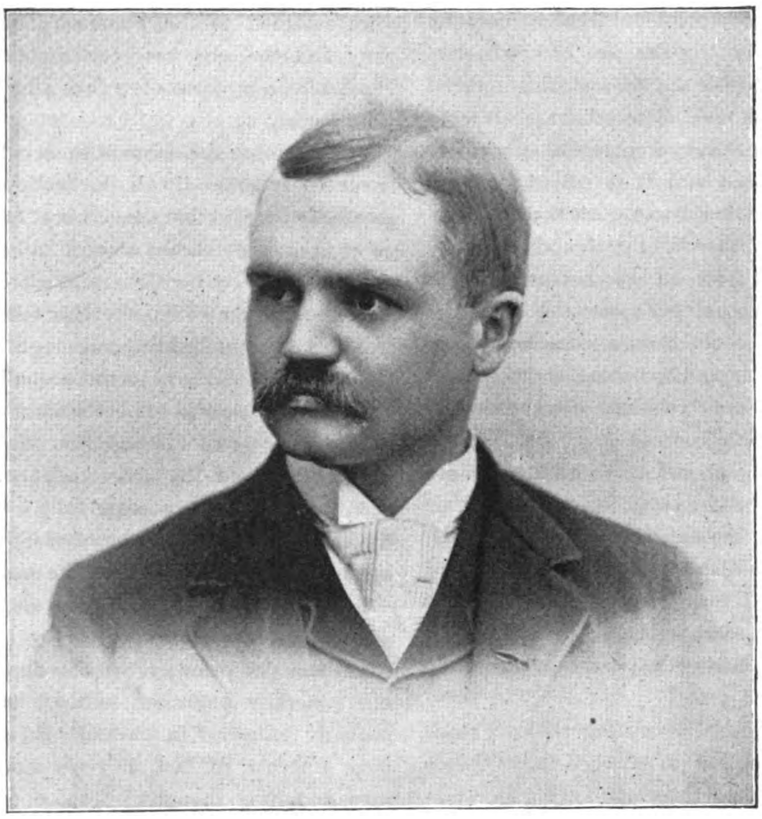
5. "Practical Aspects of Electrical Resonance," by Dr. M. I. Pupin, of Columbia College, New York City.
6. "The World's Electrical Congress of 1893," discussion of the Provisional Programme prepared by the Institute Committee. This report with its appendices has been printed in the January and February issues of the Transactions, and absent members are earnestly invited to contribute in writing any comments they desire to make.
7. "A New Method and Apparatus for Measuring Conductivity," by Mr. E. G. Willyoung, of Philadelphia.
8. "The Heating of Armatures," by A. H. and C. E. Timmerman, of Cornell University, Ithaca, N. Y.

The Novak Lamp.

Brief Sketch of the Inventor.

Among the numerous lamps which have come forward since the attempted monopoly of the styles heretofore in use, the "Novak" probably constitutes the most radical departure from the old practice, and involves a principle which has often been declared by high authorities to be impossible of application in a practical incandescent lamp.

In using a gas in the globes of these lamps the inventor, Mr. Waring, argued that to prevent "air washing" and loss of energy by heat the gas employed should possess high atomic weight, and this theory is the basis of the "Novak" lamp. From the result of the tests which have been in progress since December last on these lamps, it appears that their efficiency is fully equal to any of the vacuum lamps made, and in one respect at least they seem to be superior, as the bulbs of the lamp tested showed no signs of blackening.



JOHN WARING.

The patent for this lamp, which has recently been granted, specifies the combination of a carbon to be raised to incandescence by electrical excitement, an enveloping gas composed wholly or largely of an element or elements of high atomic weight, to wit, as high as that of bromine, a sealed chamber inclosing both the carbon and surrounding gas, and electrical conductors passing through the walls of said chamber and connecting with the carbon.

As the blackening of incandescent bulbs is due to the depositing of carbon which is taken from the filament, there follows a loss of candle power proportional to the disintegration of the latter, but if this destruction is avoided by the use of a heavy gas the "Novak" lamp should maintain practically its normal candle power during its life—a claim which the manufacturers advance for it.

In view of the timely production of a non-infringing lamp, a sketch of its inventor will be of interest.

John Waring.

Mr. Waring was born in Darlington, Wisconsin, in 1862. He received a technical education, including a course in Cornell University, from which he received the degree of Mechanical Engineer in 1884. His inclinations in the direction of electrical work led him to give special attention to this branch of study, and in his senior year he substituted a special course of physical laboratory work, under the direction of Prof. Anthony, for the regular machine shop work laid down in the course.

After graduating he began active work in the electrical field, entering the service of the Mather Electric Company, of Hartford, in 1886.

He remained with that company for four years, doing general work in the dynamo department, at the same time paying special attention to the manufacture of instruments, such as laboratory resistance boxes, voltmeters, ammeters and galvanometers. During this time he received several patents on such instruments and redesigned and improved many of the existing types, among which may be mentioned the magnetic vane ammeters and voltmeters.

In 1890 he accepted the position of electrician to the Perkins Electric Lamp Company, with whom he remained up to last February, after which, upon the production of the Novak lamp, the Waring Electric Company was organized.

Incandescent Lamp Matters.

The Sawyer-Man Case Carried to the Supreme Court.

At the session of the Supreme Court of the United States last week a petition was presented asking the court to bring up for review and determination the case of the Edison Electric Light Company et al. vs. Sawyer-Man Electric Company now pending in the Circuit Court for the Southern District of New York.

In support of the petition a brief was filed by B. H. Bristow which presents the arguments for the granting of the petition.

Counsel for the Sawyer-Man Company contend that the injunction sought ought not to be issued for two reasons:

1. That the Edison Company has been guilty of laches, and although the patent was issued in January, 1880, no action was taken to prevent its infringement until May, 1885. During all that time competitors of the Edison Company were engaged in the business of furnishing electric light plants without objections, and stockholders of these and other companies were thereby induced to invest the money in similar enterprises. All this investment, estimated at $25,000.000, counsel say, is at stake, and they argue that the court ought not to permit the Edison Company, after sleeping on its rights these five years, to reap the benefit of the pioneer work done by its competitors, the result of which has been to make the business remunerative.

2. That the Edison Company is a part of a combination the very existence of which is unlawful. Its purpose is to create and maintain a monopoly of the electric lighting business, and it cannot, therefore, have the aid of the court in carrying out the illegal purposes of its organization.

Storage Battery Litigation.

The case of the Brush Electric Company and the Consolidated Storage Company against the Milford and Hopedale Street Railway Company and the Hopedale Electric Company was heard in the United States Circuit Court, Boston, last week, before Judge Colt.

The plaintiffs were represented by Messrs. Witter, Kenyon, Bentley, Blodgett and Charles E. Mitchell, while the defendants had Messrs. W. B. H. Dawse, Edmund Wetmore, Louis D. Brandeis and W. S. Hall as their counsel.

The plaintiffs alleged infringement and asked the court for an injunction.

The patent in dispute was granted in 1886 to Charles F. Brush. Afterward the Brush Company, to whom the patent had been assigned, amalgamated with the Consolidated Storage Company or conveyed to the latter company the exclusive right to make and sell the Brush Battery.

The defendants denied the charge of infringement.

In opening the case on Tuesday morning Mr. Kenyon, of New York, gave a very full description of the Brush storage battery, pointing out its salient features, describing the process by which it is manufactured and the results attained by it when put into service.

Mr. Kenyon's opening argument also included a historical outline of the work done in this department of electrical science by Plantè, Faure and others, maintaining that what Mr. Charles F. Brush accomplished was the invention of a storage battery of unique design, high efficiency and great commercial value.

He then proceeded to show wherein the battery now being made and used by the defendants resembled the Brush device, the points of resemblance extending to the material used and the form in which they were used, the head plates being closely alike in structure, the effects of the chemical action taking place when the battery was being used being the same.

Mr. Edmund Wetmore, in behalf of his clients, by a minute description of their battery, showed that in form, method of manufacture and resultant efficiency there was the widest possible difference and therefore the plea for an injunction was unsupported by facts.

After Mr. Mitchell had addressed the court in favor of an injunction, Judge Colt took the matter under consideration and will deliver his decision at an early date.

Should the plaintiffs lose their case, a decided impetus will be given to the movement in the direction of storage battery traction.

Photographic Development by Electricity.

Combining two experiments made by Schützerberger in 1869 and Eder in 1886, Herr Liesegang, of Dusseldorf, has succeeded in developing photographic negatives by electricity. He passes the current from six Gassner dry cells through an almost concentrated solution of bisulphate of soda, containing two electrodes of platinum, separated by a porous vessel. If a photographic plate is immersed in the liquid surrounding the negative electrode, the image is developed in a few minutes with a reddish-brown tint. The liquid remains quite clear. No inconvenience is experienced from the decomposition of the liquid, as the separated elements recombine under the influence of the current. In the fixing bath it loses in intensity, but preserves its reddish tint.—*Electrical Engineer* (London).

Suburban Electric Railways. Considerable has been written lately relative to an absurd suggestion contemplating the extension of electric railways over suburban farming districts which, notwithstanding its utter impracticability, has evidently been taken seriously in some quarters judging from the published comments upon this subject which have appeared from time to time. The almost uniform success that has characterized the introduction of electric railways in cities and towns in all parts of the country lends a certain plausibility to such a scheme which appeals to the layman, who is frequently asked to believe that any and every result, however impossible otherwise, may be readily accomplished by the use of electricity. But in many cases, like the present, the financial possibilities, which must determine the ultimate success or failure of every commercial enterprise, are apt to be ignored, and it is patent to every-one versed in electric railway work that this suggestion emanates either from profound ignorance of the subject or from an over-zealous effort to dispose of electrical railway apparatus.

In view of this conclusion, a consideration of the cost of installing and operating such a system will be found of some value in determining its practicability, which from an engineering standpoint is unquestioned, and although no absolute estimate can be made to fit every case, a fair average, based on the statistics of existing roads, is sufficient to establish the futility of an attempt to connect isolated farms, or other than cities of considerable size and in close proximity, by electric railways, having in view a profit on the investment.

The great majority of existing electric roads have been introduced to succeed horse roads operating on the same lines and having an established urban traffic. Under these circumstances the substitution of electric for animal power has proved uniformly advantageous, and this fact has been assiduously urged in favor of its further application to interurban and rural transportation.

A large number of pen pictures have appeared describing a railway station centrally located in some town from which radiate a number of roads so as to cover all the surrounding districts, and which would largely derive their incomes from carrying farm produce to market. It is obvious that such support would only amount to a small fraction of the income derived from a fair passenger traffic, and it is only by careful management that roads running even in moderate size towns prove profitable. The present enthusiasm over electric roads should be tempered with the same discretion that is used in ordinary business affairs.

* * *

A BOSTON paper, not too friendly with the Electric Trust, went out of its way recently to state that the officials of this Trust were better men than the officials of the Whiskey Trust. It is doubtful if this statement can hold water much longer; certain exceptions will need to be made. Conspiracy and larceny are not as serious offences in the eyes of the law as arson, but in the eyes of decent business men little distinction could be made.

More Patent Litigation. The General Electric Company, whose prestige appears to depend largely upon the decisions rendered in its patent litigations, is now preparing an attempt to emerge from the cloud under which it fell in St. Louis, and has apparently abandoned the incandescent lamp in favor of the trolley.

The infringement suit, noted elsewhere, which has been brought against a local electric railroad in New Haven by the Thomson-Houston Company, which names the Westinghouse Company as a party defendant, is based on two patents issued to C. J. VanDepoele on April 11, 1893, which were assigned to the Thomson-Houston Company, and the suit has been brought with commendable promptness a few days after the patents were issued.

By examining the claims of these patents, which cover pretty generally all the trolleys in use to-day, it is apparent that the suit is at foundation an effort to monopolize the electric railway business of the country by the General Electric Company, after the fashion of its abortive attempt to control incandescent lighting, although in the present case there seems to be but a small fraction of the chance of success which the lamp case offered.

Of the two patents in litigation one was filed in March, 1887, and the other in June, 1888, and granting that the same cover fully every form of under-running trolley now made, the suit still seems ridiculous in view of the many cases in which the use of such devices have antedated the applications for these patents by many years. These cases of prior use are also neither obscure nor generally unknown, as they have been repeatedly described in the daily papers and technical journals; in fact, they are matters of history, and it is thought by those competent to judge that no fundamental trolley patent could legally exist at this date.

The first use of an under-running trolley of this description was in 1854, when it was used on a railroad train for telegraphing while in motion. That occurred thirty-three years before Van Depoele's application for a patent was filed. Again in 1879 the first Siemens & Halske electric railway used this same device, and it was also used on the Lichtenburg (Germany) road in 1880. A number of under-running, spring-contact trolleys were afterwards exhibited at the Paris Exposition in 1881, which, with numerous other well-authenticated cases of the use of this device, should be sufficient to negative its novelty in 1887 without any extensive argument. The same patents claim the invention of overhead switches in which the traveling conductor is depressed, or in which it is led to either wire by upward sloping paths. The claims are hardly specific enough to constitute an invention, and would be of no special value if upheld.

In view of the weakness of its case, the question as to the General Electric's motive in pressing it at this time naturally arises, and is not difficult to explain. Since the organization of this Trust, less than a year ago, its avowed intention has been to create a gigantic monopoly which would control the whole electrical business of the country, but it has needed but a few months to learn the futility of such an attempt. Like similar conspiracies to control any branch of trade, the Electric Trust has assumed an attitude of insolent arrogance toward its competitors, and has sought to crush them by every means except that of honest competition. Such a course was impossible for a concern which must needs hide its condition of bankruptcy under cover of eight per cent. annual dividends upon a capitalization of which eighty per cent. represents the proportion of watered stock. By means of every device known to financial manipulators this corporation's stock was inflated to 119 per cent. on its par value, and to further the stock jobbing schemes of its promoters, its strongest patent, the incandescent lamp, was chosen as a legal weapon to destroy all opposition to its progress. But in spite of the temporary advantage which this patent procured, the company's position began to be generally understood and its stock was looked upon with some suspicion. This marked the commencement of a steady decline which the greatest efforts of the Trust have been powerless to check, and to which the recent defeat in the incandescent lamp litigation which it sustained has lent an extra impetus, so that to-day the market value of its stock is with difficulty held at 60 per cent. of its former price.

In the present extremity something must be done to keep up appearances and boost up the stock, and the trolley suit is a final effort to stop the impending crash which must ultimately occur. It is a simple bluff which is tried upon the public, and will doubtless be worked for all it is worth until the bubble bursts and a limit shall be reached when the sale of enough watered stock to pay eight per cent. dividends becomes impossible.

* * *

The Westinghouse Report.

The first annual report of the Westinghouse Electric and Manufacturing Company since reorganization makes a very favorable showing, and the results should be gratifying to the stockholders. At least one paragraph in the report is of interest to every one:

"The results of the past year's business have shown that apparatus can be sold for cash to responsible parties, and that the prevailing belief that long credits must be given, or that stocks and bonds must necessarily be taken in order to secure business, is not correct. Your officers and agents have found that low cash prices and good apparatus are sufficient inducements to secure all the trade the company can care for."

The evils attendant on the plan of providing the money for the customer to make his purchases with do not need to be dwelt on here. It is a plan which ought never to have been introduced into this business, and which has proved a failure from the start, working injury alike to the buyer and the seller. It was a serious handicap for the old United States Company and for the Edison Company. The Thomson-Houston Company did better, as they introduced a marvellous scheme of financiering to aid them. But with this company the inevitable end has been only postponed by ingenious manipulation, and the poison is still in the system.

It is encouraging to know that the Westinghouse Company has set its foot down firmly, and that it has been successful in getting business on a business-like basis.

The cash basis also has a strong exponent in the Siemens & Halske Company, and we believe that every large manufacturing concern in the country must sooner or later stand on the same platform.

There is no reason why the manufacturer of railway or lighting apparatus should usurp the functions of the banker, the broker and the pawnbroker.

* * *

Financiering or Swindling?

The most unfortunate feature of the present condition of General Electric stock is that the guilty have escaped loss and that the innocent have suffered. It is good opinion in Wall Street that all the large holders got out some time ago, leaving the smaller investors to bear the loss. This is nothing new, it is the rule in all combinations of this nature.

It is the unquestioned privilege of a business man to sell his goods for the highest price he can get. But we would like to know by what rule of business morality the conduct of Mr. C. A. Coffin and S. V. White can be justified. One was the organizer of the General Electric Company, and has been its President from the beginning; the other was recognized until last week as the official representative of the company in the Street. Both of these gentlemen have been looked up to in their respective communities as men of honor, whose word was not to be questioned.

Both have been claiming for ten months that the stock of the company was a sound and stable investment bound to advance in price to somewhere near 150.

Both knew in the beginning, as the world knows now, that the stock is not worth par.

The shrinkage of 30 to 40 per cent. in the market price of a stock is a serious thing even for speculators; it is a much more serious thing for the small investors, the laboring classes, whose investment of $1,000 represented perhaps the savings from ten years of hard work.

Did these gentlemen do right when they used every effort in their power to force the price of this stock up to twice its actual value, and then to unload on the ignorant public of small investors?

Would they have dared to invest trust funds of which they were trustees in such securities? We think not.

Not even the elaborate Century Dictionary gives us the proper distinction between financiering and swindling. Where, then, does legitimate financiering end and swindling begin?

We will give space to both Mr. Coffin and Mr. White if they will answer this question.

* * *

A RECORD of a mile in thirty-two seconds was made by engine No. 999 on the New York Central Railroad last week. Engineers who are working at the problem of safe high-speed electric traction are thus warned that they have a long way yet to go before they can even compete with steam.

DESPITE the columns of rosy statements poured out by the Boston and New York officials of the Trust, aided by Mr. John Surething Wise, and sent broadcast over the country, Trust stock has failed to advance materially. Yet there were sceptics sixty days ago, when ELECTRICITY predicted that this stock ought to be selling at about 75.

* * *

WE ARE advised by our Pittsburg correspondent that Ashton, the go-between sent to Pittsburg by the General Electric Company, has made a full confession, and has turned over to the authorities letters, etc., bearing the signatures of the accused officials of the Trust. Confessions have also been made by one or more of the Pittsburg men.

* * *

THE *Electrical Engineer* has made a long continued and agile effort to be on the side of the winner, and we hope it is at last off the fence to stay. What a pitiable spectacle it would be to see our contemporary make another flop should General Electric go up again to par or better.

* * *

WE HAVE had occasion at different times to compare the abilities of Mr. C. A. Coffin with those of Mr. R. T. McDonald. We have said, we believe, that McDonald is a "slicker" man than Mr. Coffin, and that he ought to be Mr. Coffin's immediate successor in the Presidency of the General Electric Company. The events of the past two weeks have given force to our opinion, and we have no doubt it will be the subject for discussion at an early meeting of the Board of Directors. When was Mac. known to get rattled? Would he ever have left Wall Street in the midst of a panic, and gone off to Fort Wayne, or to Lynn, to meddle with such a small matter as a few stolen blue-prints? Has he ever been known to allow his subordinates to discuss charges of bribery or conspiracy against themselves in the daily press? Not much. Richard is superior to all these little weaknesses. Moreover, we would like to ask, in the many games which he and Mr. Coffin have played in the last few years, has Mr. Coffin ever been known to take a trick? If so, the fact has escaped public notice.

* * *

AND now comes Rialto of the Boston *Herald*, telling the Wall Street brokers that they have made a mistake; that General Electric is not a Trust; that there was no reason why it should have been affected by the slump in Industrials; that it is not a common Industrial, like Cordage and Sugar, but a gilt-edged 8 per cent. manufacturing stock, and a good buy. Rialto's Boston audience may take him seriously, but not so Wall Street. The New York nose is not so large, perhaps, as the Boston nose, but it is more finely cultivated. And several weeks ago it detected the odor of rottenness in Electric Trust stock.

* * *

IT IS a fact that $400,000 of the bonds of the Syracuse Electric Light and Power Company have been turned over to the United Securities Company, and are now held as collateral by that company against one or more of its issues of series bonds.

The Stolen Blue Prints.

The Arrested Men Waive a Hearing at Pittsburg.

Partial List of the Stolen Drawings.

There have been no further sensational developments in the matter of the charges of conspiracy and theft brought by the Westinghouse Electric Manufacturing Company against President Coffin, E. W. Rice, W. H. Knight and M. H. Hamilton of the latter company, and Morris W. Mead and others, at Pittsburg.

It is becoming apparent to every one that the views expressed in these columns last week were correct—that the charges would not have been brought by a company of sane business men without a reasonable amount of proof at hand.

General Electric officials, from President Coffin down, deny the charges, which is the only thing they could do under the circumstances. The denials will count for little at present. No one expected them to confess their guilt to newspaper reporters. They would have used better judgment if they had maintained silence.

Their denials and statements mean about as much to the worldly-wise man as the ante-election claims of a national committee chairman.

The case will be tried in court, where denials of established facts count for little. And if the Westinghouse Company cannot present *established facts*, ELECTRICITY will be very much surprised.

At the preliminary hearing of the men who were arrested in Pittsburg on the 10th, Superintendent Morris W. Mead, of the Pittsburg Bureau of Electricity, one of those charged with conspiracy, was arraigned before Alderman McMasters. He waived a hearing and will stand a trial in court. Frank Carey, John Butler and C. C. Christian, charged with larceny, also preferred a court trial to a hearing.

The hearing was fixed for four o'clock, and the office was crowded in and outside the railing. Both sides were on hand with counsel. The prosecution was represented by Messrs. Scott, Patterson and Gordon. George C. Wilson looked after Superintendent Mead's interests, John S. Robb defended Carey and Christian, and Thomas Marshall was Butler's counsel.

Mr. Mead's bail was fixed at $2,000. Christian was held in $500 bail. Butler had to furnish the same sum, and Carey also.

The matter will now go over to the June term of court, and there is little doubt that both sides will be anxious for an early trial.

The Westinghouse Company has made the following official statement:

"Our counsel was on hand before Alderman McMasters with ample evidence to establish beyond question the charges against the defendants. We were not surprised that Mead, notwithstanding his protestations of innocence, did not dare to face a hearing before the committing magistrate; nor were we surprised that the other defendants, who have not yet been served with orders of arrest by reason of their being outside of the State, failed to respond even by counsel, notwithstanding their published boasts of innocence and of a desire and readiness to meet the charges that were made. We did not take this matter up without having in our possession ample evidence of our charges, not only against the defendants who have been served with orders of arrest, but also those who are still outside the State.

"We propose to push this matter and to exhaust every lawful means to bring the conspirators to punishment. Having discovered the extensive thefts which had been perpetrated under the direction of the conspirators, and the tremendous injury it was doing to our business, we felt it our duty to ourselves, our customers and the public generally to take the course we have pursued. The statement of those connected with the General Company that we were actuated by any other motive is simply absurd."

The New England End of It.

Specific Charges of the Bill in Equity.

Following is a portion of the bill in equity filed by Warren & Brandeis, of Boston, in the suit at Salem for the recovery of the stolen papers. The omitted portions contain simply a statement as to the positions of the Westinghouse and General Electric Companies, already familiar to our readers:

"9th. For upwards of five months prior to the first day of March, 1893, the defendants, by means of bribing various employees of the plaintiff, have been regularly obtaining blue prints of drawings, designs and sketches of apparatus made by employees of the plaintiff of the character above described and copies of specifications and proposals of the character above described.

"About August 1st, 1892, the defendant, the General Electric Company, approached certain persons in the employ of the plaintiff, who had access to the rooms in which the aforesaid plans, blue prints, specifications and proposals were kept, and through secret negotiations and the payment of large sums of money bribed them to steal from the plaintiff from time to time thereafter, and up to about the first day of March, 1893, the blue prints of the most important and novel designs for apparatus, machinery or devices which were made from time to time by the employees of the plaintiff, and also to steal specifications and proposals of the character above described.

"By means of the bribery and theft aforesaid the defendant, the General Electric Company, succeeded in securing regularly from about August 1st, 1892, until March 1st, 1893, as they were prepared, blue prints and copies of specifications and proposals made by the employees of the plaintiff. The blue prints and copies of specifications and proposals above referred to were delivered by persons stealing the same from the shops and offices of the plaintiff to the defendant and particularly to Knight and Rice, who are respectively the superintendent and chief engineer of the General Electric Company. Among the blue prints so stolen and procured by the defendant, the General Electric Company, were the following:

Five thousand horse power quarter-phase generator, designed for the proposed power plant of the Cataract Construction Company at Niagara Falls.
Electric power generator for street railway work, denominated No. 0.
Electric power generator for street railway work, denominated No. 1.
Electric power generator for street railway work, denominated No. 2.
Electric power generator for street railway work, denominated No. 3.
Electric power generator for street railway work, denominated No. 4.
Electric power generator for street railway work, denominated No. 5.
Electric power generator for street railway work, denominated No. 6.
Direct connected electric power generator for street railway work, denominated No. 1.
Direct connected electric power generator for street railway work, denominated No. 2.
Direct connected electric power generator for street railway work, denominated No. 3.
Direct connected electric power generator for street railway work, denominated No. 4.
Direct connected electric power generator for street railway work, denominated No. 5.
Street car electric motor, denominated No. 3, 20 horse power.
Street car electric motor, denominated No. 3, 25 horse power.
Street car electric motor, denominated No. 3, 30 horse power.
Street car controlling device, denominated "G."
Street car controlling device, denominated "D."
Street car controlling device, denominated "E."
Ingersoll air compressor, equipped with electric motor.
Alternating current incandescent electric light generator, denominated No. 00.
Alternating current incandescent electric light generator, denominated No. 0.
Alternating current incandescent electric light generator, denominated No. 1.
Alternating current incandescent electric light generator, denominated No. 2.
Alternating current incandescent electric light generator, denominated No. 3.
Alternating current incandescent electric light generator, denominated No. 4.
Thousand horse power dynamo designed for the World's Columbian Exposition.
Special alternating current generator designed for the Narragansett Electric Light and Power Company, at Providence, R. I.
Switchboard for electric railway power station at Chicago.
Switchboard for electric railway power station at Cleveland.
Switchboard for electric railway power station at New Haven.
Switchboard for electric railway power station at Cincinnati.
Switchboard for incandescent electric lighting station at Boston.
Switchboard for incandescent electric lighting station at World's Fair grounds at Chicago.
Switchboard for incandescent electric lighting station at Scranton.
Five hundred horse power revolving transformer.
Five hundred horse power quarter-phase generator.
Two hundred and twenty kilowatt Tesla electric motor.
Sixty horse power revolving transformer.
Sixty horse power quarter-phase generator.

"10th. All of the blue prints above described, aggregating in all about one hundred and eighty (180), passed into the manual possession of Rice and Knight as agents of the defendant, the General Electric Company, at said Lynn, and are now in the possession of said Rice or Knight as such agents, or otherwise in the possession of the company."

Bids Wanted.

The Denison Light and Power Company, Denison, Texas, has secured a franchise and will construct and operate an electric light plant for the city of Elkins, O. T. They are in the market for arc and incandescent apparatus, also for engines and other material. All purchases will be made by J. R. Cullinane, secretary and superintendent, Denison, Texas.

Current Items.

Joseph Serb, a resident of San Francisco, claims to have invented a wave-power motor that is thus described in the San Francisco *Call:*

There is a wooden flume to be placed facing seaward, into which rush the breakers and run upward twenty-five feet to a reservoir built to contain 50,000,000 gallons and raised thirty feet above sea level. To carry the water the extra five feet there is a certain complicated arrangement situated near the mouth of the flume.

At each end of the reservoir are sunk two shaftings twenty-five feet deep, whereinto open pipes from the reservoir and from which others drain from the bottom into the sea. It is in these shafts that two Pelton waterwheels are to be situated.

By means of these pumps a second reservoir higher up the beach will be filled with 10,000,000 gallons of water and again the contents of the lower reservoir will be elevated still higher into a third 25,000,000 gallon tank 100 feet or so above sea-level. The novel idea of it all is that the water running downward from these three elevations will be used to operate an electric dynamo, which in turn runs the pumps.

Mr. Serb says the idea is his, and though many have invented wave-power motors of late, none have ever considered the possibility of using the power in this drain water. By the aid of this idea he calculates that only 15 per cent. of the original wave strength will be lost, and a phase of perpetual motion produced that will last as long as the ocean waves shall continue to heave.

The New York *Evening Post* says: "One street railway company in Brooklyn reports an increase of 50 per cent. in travel since the trolley was introduced upon some of its lines as a substitute for horses. As the running expenses by the electric system are much less than with the former system, the profits of street railroading are greatly increased, and it is no wonder that financiers are putting forward strenuous efforts to consolidate and control all the street railways of the city, while ambitious politicians are seeking gain by securing franchises which will prove of great value when they are needed to extend existing lines. Meantime the work of extending the trolley is going rapidly forward. To the half dozen lines now operated by it four or five more will be added in the early summer and more by fall."

Orange and lemon growing by electricity is about to be attempted by Ralph Granger, a wealthy ranchowner in Paradise Valley, near San Diego, Cal. Just southeast of the city limits he is having an electric plant put in for his house and grounds, and on its completion will have an acre of trees supplied with incandescent lights, and over all will be placed a powerful tower light to demonstrate what there is in the theory that vegetables, trees and plants develop and mature fruit more rapidly under the constant influence of a strong light than when immersed in darkness every night.

Annual Report

Of the Westinghouse Electric and Manufacturing Company.

PITTSBURG, PA., May 17th, 1893.

Your Board presents herewith its financial statement for the year ending March 31st, 1893.

It will be seen that there has been a profit from manufacturing of $1,491,817.13, and from other sources of $112,766.60, making a total for the year of $1.604,583.73. This is after charging to operating expenses the following amounts: $84.747.31 for alterations and additions to buildings; $155,484.87 for maintaining the machinery and tools in the highest order, and $58,188.86 for interest and discount.

The year began with large orders, but with only a moderate manufacturing capacity and a proportionate stock of material on hand, so that the above earnings were made under unfavorable circumstances due to the fact that the capacity of the works and the material in stock and in process had to be more than doubled during a steadily increasing press of business.

During the year the company has manufactured and installed at the World's Fair in Chicago an electric lighting and power plant consisting of twelve generators of 15,000 lights capacity each—two of 4,000 lights capacity each, one 750 horsepower generator, and several smaller ones. Six of the large generators are driven by engines having their shafts connected directly to those of the generators. This plant is the largest ever installed.

These generators mark a new era in electric light and power distribution. They are of the "two-phase" type, designed to drive Tesla motors, and at the same time to operate both arc and incandescent lamps, thus making the one form of generator useful for three purposes.

The total capacity of the plant exceeds the contract requirements sufficiently to meet the demands that may be made by exhibitors for extra lights.

The company will also have at the Fair an extensive exhibit of its other forms of apparatus.

The stopper lamps now being manufactured in the company's Allegheny City Works are being used exclusively in connection with the apparatus at the World's Fair. It is gratifying to be able to announce that in the manufacture of the Sawyer-Man stopper lamps all of the advantages anticipated have been fully realized. The low cost of manufacture and the high efficiency of these lamps, together with the ability to renew their carbon burners, enable the company to sell lamps at lower prices than can be afforded by any other manufacturer. To meet the demand a new factory has been equipped with special machinery designed for the purpose, and already has a daily capacity of 5,000 lamps, which is being rapidly increased, and will be shortly quadrupled. The expenses incident to the establishment of this new lamp factory have been charged to the business of the past year. This branch will hereafter add materially to the volume and profit of the company's business.

The success of the stopper lamp, its low cost of manufacture, and the fact that it is the discovery, prior to Edison's patents, of inventors whose patents belong to our company, have turned a temporary check into a great business advantage.

Our competitors have copied our plans and infringed many of our patents, notably those relating to power transmission, and many important details essential to the successful operation of alternating current apparatus for the distribution of electricity for light and power purposes, for which we have brought suits for infringement.

The confidence expressed in the last annual report in the superior merit of the apparatus of the company, and in the strength and value of its patents, has been fully justified by the results of the year's operations; and we feel no apprehension as to the outcome of suits now pending or which may be brought by its competitors.

Your directors have been brought face to face with the fact that the business of the company has outgrown the present capacity of the factories, and that large savings could be effected if the manufacture were carried on in new works equipped with the latest devices for handling its product by machinery.

In view of the favorable result of the past year's business, and of the volume of orders in hand, and the future outlook, your directors have not hesitated to accept a proposition from the East Pittsburg Improvement Company to sell to your company a site of 23 acres most favorably located with reference to railway facilities. The Improvement Company has agreed to erect on this site buildings and works according to the plans and under the supervision of the officers of your company, and to sell them to the company at their actual cost, not however to exceed $500,000 above the price of the land, and have agreed to take pay therefor in quarterly payments of $25,000 and interest, beginning January 1, 1894. Your officers have estimated that the savings to be effected by the manufacture of its products in the new works, will, on a most conservative basis, be more than double the amount of the quarterly payments, Thus, these new and complete works will be acquired without the expenditure of fresh capital, leaving the proceeds from the sale of the company's present property as working capital, without taking into account the manifold business advantages that will arise from the centralization of its manufacturing operations.

The results of the past year's business have shown that our apparatus can be sold for cash to responsible parties, and that the prevailing belief that long credits must be given, or that stocks and bonds must necessarily be taken in order to secure business, is not correct. Your officers and agents have found that low cash prices and good apparatus are sufficient inducements to secure all the trade the company can care for.

Although the profits of the business might have justified the payment of dividends on all of the stock of the company, the directors have thought it wise to pursue a very conservative policy, especially in view of the large expenditures required during the past year for machinery and material, and of similar expenditures which the present prosperous condition of the company's business may make necessary in the near future. Both the results and the prospects are so encouraging that the directors believe the stockholders will uphold them in a course which places the company in a position of undoubted financial strength, and which will assure the permanent continuance of dividends when once begun.

For the Board,
GEORGE WESTINGHOUSE, JR.,
President.

Balance Sheet, March 31, 1893.

ASSETS.

Cash in banks	$212,573.85
Bills receivable	366.228.47
Accounts receivable	2,289,982.70
Material in stock and in process of manufacture (at cost of labor and material)	1,414,662.31
Advances to leased companies	138,573.06
Bonds (par value $369,100)	358,197.15
Stocks (par value $6,469,257)	4,069,439.96
Real estate and buildings	453,037.98
Machinery and tools	710,023.61
Miscellaneous	60,055.54
Charters, franchises, patents, etc	4,378,031.69
Total assets	$14,450,806.32

LIABILITIES.

Accounts payable			$569,660.48
Bills payable, issued for merchandise			376,003.64
Discounted with collateral			931,884.51
CONTRACT AND CONTINGENT LIABILITIES.			
Scrip dividend			194,562.00
Stock subscriptions			13,125.00
U. S. E. Ltg. Co.'s 6 per cent. 15 year bonds, $50.000 payable annually			600,000.00
(Bills receivable under discount, $482,054.49.)			
CAPITAL STOCK.

Dividends	256.608 32	307,282.04	
			2,757,649.19
			$14,450,806.32

The officers of the company for the year are as follows:

Chairman, Brayton Ives; President, George Westinghouse, Jr.; First Vice-President and General Manager, Lemuel Bannister; Second Vice-President, G. W. Hebard; Assistant General Manager, W. F. Zimmermann; Secretary and Attorney, Charles A. Terry; Treasurer, Ph. Ferd. Kobbe; General Agent and Assistant Treasurer, W. C. Clark; Auditor, F. H. Ketchum; Directors: Charles Francis Adams, Lemuel Bannister, August Belmont, N. W. Bumstead, A. N. Byers, Marcelus Hartley, George W. Hebard, Henry B. Hyde, Brayton Ives, George Westinghouse, Jr.

Legal Notes.

At Norwalk, Ohio, on the 25th ult., Judge Thomas issued an order to J. W. Foster and F. H. Jones, assignees of the Incandescent Light and Power Company of Norwalk, to sell the company's property at public sale for cash. The assignees have not yet determined on a date of sale. The property was appraised a few weeks ago at $35,025.

The street-railway company in Paterson, N. J., erected poles and wires in one of the streets in the city. A property owner in the street cut the wires in front of his dwelling and the railroad company applied for an injunction restraining him from causing further damage. Vice-Chancellor Green in his opinion in the case says that the property owner had no right to cut the wire; that when a public use authorized by law takes no property, but merely affects it by proximity, the necessary interference occasioned by such use furnishes no basis for damages. It must be an interference with the rights to light and air. The Vice-Chancellor decides that the court could not grant an injunction, because the railroad company had not complied with the act of 1892 which requires that authority for stringing wires shall be obtained from the State Subway Commission.

George P. Altenberg and Rudolph Kleybolte, of Cincinnati, whose suit against the Citizens' Electric Light Company of Louisville for an alleged breach of contract, begun at Covington was transferred to the United States Court at Louisville, have received information that the demurrer presented by the Citizens' Company had been overruled by United States Judge Carney, who directed the Citizens' Company to prepare for trial within sixty days. The ground on which Altenberg and Kleybolte brought suit is that they contracted to reorganize and rebuild the Louisville Company and its plant, and were to put in $100,000 additional capital. They allege that the Citizens' Company came to a square "back down" on this contract and signed terms with the Thomson-Houston Company. The plaintiffs then tendered their $100,000, they claim, and it was refused. They sued for $101,500, the $1,500 being expenses, and the Citizens' Company presented a demurrer to the effect that the contract was only an option.

In the case of the Accumulator Company of Philadelphia against the Dubuque Street Railway Company, at Dubuque, Iowa, the jury brought in a verdict in favor of the latter. The suit was brought by the Accumulator Company to recover for the storage-battery equipment in use on the road, amounting with interest to $6,000. The president of the road filed a cross-suit for damages, claiming that the storage-battery system failed to do the work guaranteed. The case was contested by the ablest lawyers in Dubuque.

In the injunction suit brought by the Schuyler Electric Company against the street commissioners of Hagerstown, Md., to prevent them from completing a contract made with a street railway company for lighting the streets as a condition of a road grant, Judge Stake has filed an opinion denying the injunction. The case will probably be carried to the Court of Appeals.

The VanDepoele Patents.

Infringement Suits Brought in Connecticut.

The Thomson-Houston Company has brought suit for infringement against the Winchester Avenue and West Haven Electric road in New Haven, and the Westinghouse Electric Company of Pittsburg is made party defendant in the case.

The complaint alleges infringement of two trolley patents issued to C. J. VanDepoele, April 11, 1893, and assigned to the Thomson-Houston Company, for which the applications were filed in the Patent Office in 1887 and 1888. An injunction is asked for restraining the defendants from using their present trolleys, and the suit is brought as a test case.

It will probably be several months before a preliminary hearing is reached.

An Important Decision.

Judge Coxe, of the United States Circuit Court, has decided adversely to the plaintiff in the matter of Edison Electric Light Company et al. vs. the Equitable Life Assurance Society.

The suit was brought for infringement of various Edison patents on fixtures, sockets, etc.

The Court holds that since the alleged infringement was begun eleven years ago and continued until the present time without any suit having been begun, the plea of laches entered by defendants must be allowed. The plaintiff was not entitled to either a restraining order or a permanent injunction; plaintiff could only have been injured to the extent of his license fee, and the right to recover that has been lost by negligence.

Eugene H. Lewis represented the plaintiff, and L. E. Curtis the defendants.

World's Fair Department of Electricity.

For the second time since the opening of the Exposition all of the electrical apparatus in the Machinery Hall that has been completed was put to a thorough test in illuminating the grounds and buildings last Saturday evening.

The first time it was put into actual operation was on Monday, although not all of the generators were in shape to be used at the initial trial.

The first public exhibition in which the great MacMonnies fountain played the leading part was also on the programme for Saturday evening. Judging by the large crowd of visitors gathered around the fountains on the opening night, they will be one of the most attractive features of the Exposition for those who visit the grounds after sundown.

The beautiful exhibit of the Western Electric Company, which is located in the southwest corner of the Electricity Building, was also given its initial trial last week. A unique part of the exhibit consists of a column of incandescent lights of various colors running from the floor to the ceiling and branching off to the four points of the compass in the shape of zigzag lightning. Each of the series of the imitation lightning flashes terminates in a large ball covered with lamps. The different circuits of lamps are connected to an automatic switch in such a manner that the current will pass through each lamp in succession in the column, beginning at the floor and then through the lamps mounted on the zigzag board. The effect produced is a very good imitation of natural lightning.

The Ansonia Electric Company has put a number of extra men to work on their booth and expect to have it completed within the next ten days. The exhibit will be an extremely novel one, especially to the ladies visiting the building. In the booth of the company, which is located in the north wing of the gallery between the two restaurants, will be placed a number of heating devices for cooking the greater portion of the meals served at the tables.

Most of the exhibitors in Section Y, or Newspaper Row as it is familiarly called, have moved into their quarters and have representatives on hand to entertain guests.

The W. D. Graves Company.

Where the Cash Went.

Expert Accountant F. R. Merchant, who has been at work on the books of the W. D. Graves Company of Cleveland for three months, has completed his labors. He states that the Cleveland Electric Light Company is debtor to the Graves Company $11,541.95 for labor and material and $10,000 of borrowed money. Mr. Frank J. Stafford was the treasurer of the Graves Company and also of the Cleveland Electric Light Company, which latter company is a part of the Cleveland General Electric Company.

Power House Burned at Rochester.

The train house, power house and coal yard of the Grand View Beach Railroad were totally destroyed by fire on the morning of the 10th at an early hour. There were 500 tons of coal stored in the bins for the summer's business. The loss is estimated at $60,000 and is fully covered by insurance.

The equipment burned was fifteen cars, two 125 H. P. generators, three McIntosh & Seymour engines and three 100 H. P. boilers.

Long Distance Transmission.

Power from Niagara Falls to be Carried to Albany.

A syndicate was formed in New York City, May 11, with a capital of four million dollars, for the construction and equipment of a line between Niagara Falls and Albany, for the transmission of electric power generated by the Niagara Falls Power Company.

The plan is the most ambitious one yet proposed in connection with the Niagara Falls scheme, and the syndicate is said to be thoroughly in earnest.

It is as yet too early to say that the plan, carried to completion, would prove a dangerous competitor for the local central stations in the central part of the State, but that, of course, is what the promoters expect it to be.

General Electric.

What is Said of It Nowadays.

General Electric continues to display a weak tone, but the Morgan-Vanderbilt interest is so strong in this company that a powerful protection overcomes the effect of both liquidation and short sales of the stock. Purchases for insiders alone sustain the stock, as the affairs of the company are in much suspicion.—*New York Advertiser.*

More than room trading, rumored suits for conspiracy and sympathy with the other industrials is responsible for the tremendous slump in the price of General Electric stock. Stockholders have just had enough time since the publication of the company's last report to reflect on the conditions of the properties. It is pretty generally believed that under the Villard administration Edison lost money on every contract for plants on the cruisers belonging to the "White Squadron" and on many other of their larger contracts for installations outside of New York City. Only a close investigation of the books and records of the General Electric Company will show what investigators want to know. The annual report contains nothing.—*Wall Street News.*

Marked for Slaughter.

(From the Daily American.)

As for General Electric, there does not seem to be any doubt that it is booked for very much lower figures. The impression seems to be that the company is run on a ridiculously extravagant basis, and a lot of the smaller concerns that were taken in when the company was first organized were taken under an arrangement whereby their claims are satisfied before any of the earnings can be applied on the stock. There are those who profess to believe that a reorganization of the property is one of the possibilities of the near future, and, of course, in that case the price will break to 50 or below. Under present conditions it is a good stock either to leave alone or to sell for future delivery. The brilliant and triumphant bears of the Street have marked it for slaughter, and yesterday's developments show that the friends of the stock are giving it no support.

Mr. Coffin's Admissions.

The General Electric Company Has Failed to Meet Some of Its Obligations Promptly, and is not in Easy Financial Condition.

A director of the General Electric Company recently wrote to President Coffin as follows:

DEAR SIR: The stories about General Electric Company's bad financial condition and poor business still continue. Please answer categorically each of the following questions, which will suggest to you the rumors now current, viz.:

1. Has the company at any time this year been disturbed in any of its loans or been in any instances refused such accommodation as it has desired, or in any instance failed to meet all obligations promptly?

2. Has it sought any unusual accommodation during the past three months?

3. Do the company and the sub-companies owe more money to-day than on Jan. 31st, 1893?

4. Do you contemplate issuing any additional stock or bonds of the General Electric Company, or any of its controlled companies?

5. Is the company in perfectly easy financial condition, and is there likely to be any change in this respect?

6. Do you know of any reason, financial or otherwise, why stock of the General Electric Company cannot be safely and strongly recommended as a perfectly safe and sound 8 per cent. investment, or why its future should not be at least as prosperous as its annual report shows its past to have been?

Please answer by wire "yes" or "no" to each question, by number, and then amplify as much as you choose.

Mr. Coffin replied:

DEAR SIR: Your letter received this morning. I can answer categorically to each one of the questions "no," except the first part of your inquiry, and to that I answer "yes."

There are industrious reports in circulation to the effect that we are selling a large part of our apparatus with a contract to take in payment therefor stocks and bonds.

To meet this we shall publish in the financial papers this morning a statement to the effect that of $3,000,000 of railway orders now on hand—which is largely in excess of a year ago—the entire amount is sold for cash and well secured notes, about 80 per cent. of the former and 20 per cent. of the latter, with no obligations to take stocks or bonds for any part thereof.

The sales of lighting apparatus are also almost exclusively for cash or well secured notes. Very truly yours.

(Signed) C. A. COFFIN.

Attention!

Electrical Ladies and Gentlemen can Start Cheaply.

(From the New York Herald.)

$25 STARTS LADIES OR GENTLEMEN IN BIG paying professional office business; particulars free. Call Monday, W. U. Electric Co., 26 Whitehall st.

Mr. TERRILL.

Frozen Truth.

A Fact Beyond Dispute.

(Mr. C. A. Coffin in Boston Herald.)

"General Electric is worth as much money and is just as solid as it was six months ago."

Electric Stone.

The Galveston *News* prints the following telegraphic dispatch from Uvalde, Texas: "A few days since a Mexican trapper rode up to the jewelry store of J. F. Nance in this city and sold him a small stone for $5. It is pronounced by old miners and other citizens of the place to be crystallized carbon. It is either heavily charged with electricity, or else it acts as a conductor. By placing one's hands upon it distinct and almost severe electric shocks are transmitted through the body. Hundreds have visited the jewelry shop to witness this new wonder, the like of which it is safe to say, there is not another in the world. It is shaped like a disc, is transparent, flat at the bottom, about as thick as a grain of Indian corn, and about one-third of an inch in diameter, thickest in the centre, and gradually tapering to its edges. The Mexican said that it came out of a volcano in Mexico. None of those who have seen it have ever heard of or seen anything like it, but several think that it is pure carbon."

Mathematics In Place and Out of Place.

(*From The Electrician, London, April* 21.)

Mathematicians in search of new pasture, and practical men anxious to see what will happen when the "professor" is eliminated, should peruse a paper on transmission of power, recently read before the National Electric Light Association by Mr. L. B. Stillwell. "We may conveniently construct an algebraic skeleton," says the author, and he forthwith proceeds to do so. Whether this skeleton is to be kept in a cupboard, and only taken out at Institution meetings from which the professors will have already been eliminated, we are not informed. Here is the skeleton, or a small part of it: "Fh—First cost of hydraulic plant, including turbines, dams, flumes, etc. Ph—Percentage covering interest upon and maintenance of hydraulic plant. Oh—Cost of oil and waste per annum for hydraulic plant." And so on, and so on. Then we arrive at the following mathematical equation, which, at first sight, we took to be a chemical equation in which iron and carbon, oxygen and nitrogen, and several unknown elements—which, doubtless, were the undiscovered members of Mendelejeff's celebrated cycles—had got considerably mixed up: "PbFb + Cb + PhFh + Oh + Ch + AN + PeFe + Oe + Ce + PlFl + Cl = annual charges." "And now," continues the author, "what have we accomplished?" What, indeed? As a piece of anatomical mathematics this cannot compare with the efforts of the man who can cover the Institution blackboard with formula three times before members have had time to get their pencils out of their pockets; but as a piece of practical intelligence, it is a mere string of labored nothings, calculated to "amaze the unlearned and make the learned smile." Let *Sh* be the shovel at the station, *Sw* the switchboard, and so on; then the equation to the station is $Sh+Sw+MeN+BeEr+BaC^2y+$ etc., which is a parallel piece of mathematics.

If electrical engineering cannot get along without mathematical treatment, then, *pollice verso*, let the mathematician live, and let us employ him to do the necessary work. But if, forsooth, it can, where is the advantage in this spurious semblance of mathematical form, which is the mania of some un-mathematical men? The pressing of mathematics into places where they are not needed is as foolish as their exclusion from places where they are essential. Undoubtedly, there is an unfortunate tendency nowadays to overburden every branch of electrical work with mathematics, to the detriment of practice. Other subjects, other industries, might equally well be mathematically treated. We have seen a series of elaborate equations, involving trigonometry and the theory of impact and elasticity, explaining a game of cricket; and it would be quite possible to write a book full of triple integrals and slant co-efficients in three dimensions, to explain the operations involved in carving a statue. Mathematical form, unless there be in it the breath of practical life, is, indeed, a skeleton; and it would be labor ill-spent to try and galvanize it into living activity. There is not the least objection to the application of mathematics to cricket; but they remain mathematics, they do not become cricket. Prof. Tait has indeed not only applied mathematics to golf, but has done much better service in applying golf to mathematics, and with most interesting results. But these results were no longer within the province of golf; they formed a valuable contribution to our knowledge of elastic bodies and impact. To deny that mathematics are essential to progress in the higher branches of engineering, is to confess ignorance of those branches; but to burden elementary work with abstruse calculations and with pedantic definitions is likely to bring about contention between the practical man and the theorist. A pedant is all very well in his place, but he should not come into the workshop and snub the man at the vise.

A distinction should be observed between accuracy of elementary knowledge and high theoretical attainments. It is important that every engineer should have exact and clear ideas as to the relations between force, power, work, and energy, and the electrical engineer must be familiar with other electrical relations. These elementary laws have an apparent connection with mathematics, because mathematicians have defined them. But the mathematics of Ohm's law go no farther than the rule of three. If some of the simple facts of engineering and of electrical science could be divested of the mathematical garb in which professors delight to clothe them, the beginner would advance with much less hesitation. He is too often presented with a fact swathed in algebraical attire, bound with many a hard and knotted formula, and decked with streaming expanded terms, tasselled at the end with " +, etc." He ultimately makes acquaintance with the fact itself and this acquaintance continues long after the mathematical millinery has been discarded by the mind.

A sailor has a good deal to learn before he need trouble himself about taking lunar distances; and a soldier must be familiar with squad drill before he makes an acquaintance with brigade drill, and he may do excellent service as a tactician without aspiring to strategical accomplishments. Every French soldier is told that he carries a field-marshal's *baton* in his knapsack, and, with hardly more sense of fitness, young engineers and electricians are encouraged to equip themselves with a mathematical armory such as might enable them, if they had the wit, to take a hand in original research of a high order. That is where the waste and the pedantry come in. Theory, and, if need be, mathematics, in healthy co-operation with practical work, are to-day essential for real progress. The rule-of-thumb man progressed, it is true, but not fast enough for to-day. The ready mathematician, on the other hand, is apt to ignore essential conditions and to rush on wildly with loose assumptions, conjectural data, and vague hypotheses, imagining all the time that he is an engineer.

Legal Notes.

Mrs. Elizabeth Mahoney, of Elizabeth, N. J., has brought a suit for $2,000 against the Suburban Electric Light Company of Elizabeth for injuries she received by the fall of an electric arc lamp on her as she was walking along the street.

The San Francisco *Call* states that by consent of counsel, Judge McKenna, in the United States Circuit Court, has dismissed the suit of the Brush Electric Light Company vs. the Nappa Thomson-Houston Electric Light Company. The suit had been pending since 1891, when the Brush Electric Light Company, an Ohio corporation, was working with the California Electric Light Company of San Francisco. It appears that in a similar suit for infringement of patent, instituted by the California Electric Light Company against the Electric Light Company of San Jose, the evidence showed that the California Electric Light Company had been depending on the co-operation of the Brush Company. But it also appeared that the Thomson-Houston Company had, at this time, an interest in both the Brush and the San Jose Company, and that the case was quashed.

Removal Notice.

Mr. Fremont Wilson has removed his offices to the eleventh floor of the Vanderbilt Building Annex, Nassau and Beekman streets, New York City.

The Muncie Electrical Works.

One of the candidates for popular favor in the electrical line is the Muncie Electrical Works, Muncie, Ind.

The new company began business May 1 with orders on hand sufficient for a paying business for the next six months. Mr. F. C. Field is the electrician, and James Chamberlin is general manager.

Boston Notes.

Mr. Platinum Baker, lately returned from a business trip abroad, was in Boston last week.

Mr. L. J. O'Reilly, representing Alexander, Barney & Chapin, of New York, was a Boston visitor last week.

Mr. C. L. Edgar, superintendent of the Edison Illuminating Company, Boston, is visiting Chicago on business for his company.

A committee appointed by the citizens of Marblehead, Mass., visited Boston a few days ago to inspect plans with a view to their adoption for a local electric lighting plant. A municipal plant is what the town has decided upon, and work on its building is expected to begin at an early date.

The new central station of the Haverhill Electric Company was dedicated last Monday evening in the presence of a large and representative gathering of citizens.

Mr. W. R. Goodman, the live representative of the Independent Electric Company of Chicago spent a few days in Boston this week, and called upon us during his stay at the Hub. He report business in an excellent condition with his company.

The Electrical Juniors of Lynn held their first annual reception at the Scientific Club House in Lynn last Saturday evening. They entertained the Minors' Club of East Saugus and the Electrical Juniors of Boston. Mr. R. E. Willard, of Philadelphia, delivered an interesting address on the Transmission of Power.

After frequent hearings before a legislative committee and several spirited debates in the House, the bill presented by the Cambridge Storage Battery Railway Company was passed for engrossment. It now looks as if, ere long, street cars would be running by electricity but without the aid of the overhead trolley.

Boston appears to be destined to become somewhat of a centre for the electric heating business. Several companies have been organized and are getting well under way. Ere long there will be many novelties placed on the market that are intended to revolutionize the art of heating. The companies we allude to are to make a specialty of domestic heating in its various ramifications.

Mr. I. L. Matson, who recently commenced business as electrical engineer and contractor, has secured the contract for equipping the new dormitory at Harvard University with several hundred lights.

Chicago Notes.

Mr. T. S. Palmer, manager of the Electric Heat Alarm Company of Boston, has returned home after a two weeks' stay in Chicago. A Western branch of the company has been established here, and has been placed in charge of E. N. Nashold.

Mr. Albert Hay, president of the Robison Radial Truck Company, made a number of calls on the railway supply companies of Chicago last week.

Harry Bishop, Western representative of the Massachusetts Chemical Company, received the sad news of his mother's death at Springfield, Mass., on his return from Boston, last week.

The Chicago Incandescent Lamp Company, owing to the growth of its business, has increased its capital stock to $20,000.

City Electrician Barrett in pursuing his former policy of burying or bunching all overhead wires, has compelled the different electric companies using wires in the recently annexed Hyde Park district to string all their circuits on one line of poles, and at points where they cross the trolley lines they are to be run under the streets.

Morgan Brooks, of the Engineering and Supply Company of St. Paul, was in Chicago last week.

Clark & Marshall have received their first shipment of Rowley Storage Batteries, for which they are general agents. The firm have recently moved into larger quarters in the Rookery Building.

General News.

What is Going on in the Electrical World.

Erie, Pa.—The contract for lighting the city has been awarded to the Edison Company.

Baltimore, Md.—The electric railway to Roland Park is completed and cars are running regularly.

Lincoln, Neb.—The Burlington Beach electric railway has been sold to the Lincoln Street Railway Company for $45,000.

Milwaukee, Wis.—The Milwaukee and Wauwatosa Motor Railway Company have decided to equip their line for electricity as soon as it can be done.

Marshfield, Wis.—The city council has closed a contract with the Marshfield Water and Electric Light and Power Company for lighting the city with electricity.

Dunkirk, Ohio.—A charter and right of way have been secured for an electric railway between Red Key and Dunkirk. The company will also furnish electric light for both places.

New Haven, Conn.—A power house for the Morris Cove electric road is to be erected in Fair Haven. The State street road will have an electric equipment by the middle of July.

Salt Lake, Utah.—The city council has ordered the city attorney to draft an ordinance compelling telegraph and telephone companies to pay a rental on every pole erected by them in the city.

Providence, R. I.—The Union Railroad Company will probably abandon the cable on a large portion of its line and substitute electricity, retaining the cable for use on the heavy grade in College street.

Washington, D. C.—The directors of the Washington and Great Falls Electric Railway have decided to begin the construction of the new line at once. It is their intention to push the road to completion at an early day.

St. Louis, Mo.—The stockholders of the East St. Louis Electric Street Railway have authorized an increase of capital stock from $150,000 to $500,000. The avails of the new issue are to be expended for extensions and improvements.

Rochester, N. Y.—The power house of the Grand View Beach electric road was burned to the ground on the 11th inst. Thirteen cars, 500 tons of coal and all the tools and appliances were destroyed. Loss $60,000, covered by insurance.

Mobile, Ala.—The Mobile Street Railway Company are erecting a power house and preparing their road for the change of motive power to electricity. They expect to complete the electric equipment of their lines by the last of July.

Batavia, N. Y.—Mayor Sanford has made temporary arrangement with the Consolidated Gas and Electric Company for lighting the streets. This arrangement will probably last until some definite plan of lighting has been decided upon.

Muncie, Ind.—The Citizens' Electric Street Railway Company was victorious in its suit with the Muncie Street Railway Company in the injunction proceedings. The Electric Company will now proceed with work in laying track, and will be running cars in a few weeks.

Jersey City, N. J.—The new line of the Consolidated Traction Company connecting Newark and Jersey City has been completed. The road enters Jersey City at Westside and Communipaw avenues, where it connects with the electric line that runs to the Cortlandt street ferry.

Savannah, Ga.—The option of the Electric Railway Company to continue its lease of the Savannah and Isle of Hope road expires on the 20th inst., and it is considered probable that the lease will not be renewed. In that case the electric company will extend its line to Thunderbolt and also build to the Isle of Hope.

Knightstown, Ind.—A company has been organized to build an electric railway from New Castle to this city and to the Indiana Soldiers' and Sailors' Orphans' Home, two miles south of here. The line will be constructed to pass by Greensboro or Spiceland, and the work of securing the right of way will be commenced at once.

Fort Worth, Tex.—There is a prospect of the building of a rapid transit line between Fort Worth and Dallas this year. The motive power has not been fully decided upon. Electricity is preferred, but the form of motor will depend largely upon the improvements that may be made during the time the road is under construction.

Warren, Ohio.—An electric railway to connect this city with Sharon, Pa., is proposed. A. B. Minnix and John Cole, of Vienna, have already secured three-fourths of the frontage right of way between the two cities. An application for a a franchise will be presented to the county commissioners at an early day. The route is to be the direct highway, and calls for a 16-mile line.

Hackensack, N. J.—The directors of the Bergen Turnpike Company at a meeting in Hackensack last week elected Andrew C. Zabriskie president, George W. Wheeler vice-president, Charles B. Place secretary, and William A. Paepke treasurer. It has been intimated that the new directors intend to build an electric railway from Hackensack to connect with lines in Jersey City and Hoboken.

Findlay, Ohio.—The county commissioners have granted to George B. Kerper and other Cincinnati capitalists a franchise for that portion of the Put-in-Bay, Southwestern Electric Railway lying between this city and Fostoria. Work is expected to begin on the new road within a short time. The city council of Fremont have also granted a franchise for the railway to run through Fremont.

Topeka, Kan.—The $600,000 mortgage of the old Topeka Rapid Transit Railway Company which was held by the Metropolitan Trust Company of New York has been released, the Topeka Railway Company, which company purchased the line of the Rapid Transit Company and assumed its obligations, having arranged for its payment under a mortgage for $1,100,000 on all its street lines issued to the Manhattan Trust Company of New York.

White Plains, N. Y.—Hon. Samuel Conover has purchased the franchise of the Tarrytown, White Plains and Portchester Electric Railroad, and it has been decided to change the name to the Elensford, White Plains and Mamaroneck Railway Company. The directors just elected are W. P. Hix, New York; S. W. Parker, Mamaroneck; Samuel Conover, White Plains; F. W. Leonard, J. H. Vails, Harvey Dew and Josiah Brown, New York; J. H. Moran, White Plains, and U. A. Krepps, Kensico.

Leavenworth, Kan.—The Leavenworth Railway Company has been reorganized and the following officers elected: Col. H. L. Turner, of Chicago, president; Gen. A. B. Nettleton, secretary, and W. F. Putnam, treasurer. The board of directors consists of Gen. A. B. Nettleton, Col. H. L. Turner and Messrs. W. F. Putnam, Harry L'Earle, Geo. A. Baker, William Dill and W. A. Stacey. The capital stock of the company is $500,000. Work on the electric road will be hastened by the reorganized company.

Cleveland, Ohio.—It is said the new power house of the Cleveland General Electric Company will have a capacity when completed for 2,000 arc lights, 100,000 incandescent lights and 1,000 H. P. for power service. The company will use the Edison three-wire underground system for the heart of the city and an alternating and high tension direct circuit for the suburbs. It is expected not only to furnish motive power and arc and incandescent lighting, but also to supply electricity for heating and cooking purposes when the machinery and inventions for making electricity thoroughly practicable and economical for these purposes are perfected.

Manchester, Conn.—A special to the Hartford *Courant* from Manchester says: "The Waring Electric Lamp Company has been organized with a capital of $50,000 and will manufacture an incandescent electric lamp, to be known as the Waring 'Novak' lamp. The directors in the new company are N. T. Pulsifer, of Manchester; A. D. Coffin, of Boston; J. H. Walker, of Boston; and John Waring and M. S. Chapman, of Manchester. Mr. Chapman is president and Mr. Pulsifer secretary and treasurer. The lamp will be made at the factory formerly occupied by the Perkins Company and business will be begun on a large scale immediately."

Detroit, Mich.—A dispatch from Toledo to the *Free Press* conveys the information that Toledo is soon to be connected with Detroit by an electric railway, the right of way for which has already been secured. This statement seems wholly credible from the fact that an electric railway, which is doubtless designed as part of the system, already extends south of Wyandotte, and a franchise has been granted for its extension to Trenton, about one fourth the distance to Toledo. It has for some time been known that a right of way had been acquired from Wyandotte south, and the fact that no right of way was sought between Detroit and Wyandotte lends probability to this utilization of the Detroit and Wyandotte road.

Willimantic, Conn.—The Women's Club of Willimantic, Conn., held their last regular session for the season on Tuesday evening of last week. In its report of the meeting the *Journal* gives the following particulars: "The regular programme was opened by Miss Maud Remington with two gracefully rendered violin solos. Miss May Davison discussed the Telephone in an interesting manner, illustrating her talk by drawings done by Miss Houghton. The next subject, 'Electric Lighting,' was presented by Mrs. Beede in a brief practical talk. Mrs. Hamlin's paper on 'Electric Railways' was excellent. Mrs. Nellie Crane read an article on 'The Electrical Department at the World's Fair,' written by W. W. Prime, engineer of that department."

Wrought Iron for Field Magnets.

The Commercial Electric Company of Indianapolis have issued a new catalogue describing their lines of dynamos and motors which include some refinements in construction worthy of attention. One of the principal points in these machines is the exclusive use of wrought iron for their fields. The all forged iron construction has heretofore been considerably employed where the sizes of the machines permit the use of drop forgings, but beyond this it has not so far been generally adopted on account of its extra cost, although its superiority for this purpose is well known. Somewhat less than half the necessary section of cast iron is sufficient for wrought iron fields as the same magnetizing force generates more than twice the number of lines of force in the latter as it does in the former at the point of saturation generally chosen. This, of course, means a great reduction in the weight of wrought iron in the fields, and a saving in the copper on the fields due to their smaller section.

In these machines up to the ten horse power sizes, large Gramme ring armatures are used, requiring but one layer of wire for 110 volt and two layers for 500 volt machines. This is of advantage in two ways as it not only reduces the armature resistance but decreases the magnetic resistance by diminishing the length of the air gap. In larger sizes drum armatures are used, in the construction of which the same principles are followed, and the mechanical details throughout have been carefully perfected.

Motors and dynamos of standard voltages and for various kinds of work are described in the company's new catalogue, to which they invite attention.

Enterprise is Appreciated.

The Star Electric Lamp Company is receiving many letters congratulating them on the energy and push which have enabled them to produce a commercial lamp and get it ready for the market so promptly. This company, it will be remembered, was the first one to announce a non-infringing lamp. The lamps that have been delivered are proving highly satisfactory and orders are coming in very rapidly. This must of course be very gratifying to the Star Company, who have been to great expense in pushing their experiments forward, and no doubt pleases them to see that the electrical fraternity appreciate their efforts by the liberal reward in the way of orders.

Large shipments are now being made, and the universal verdict is that the New Sunbeam is superior in every way to the vacuum lamp.

The Cutter Specialties.

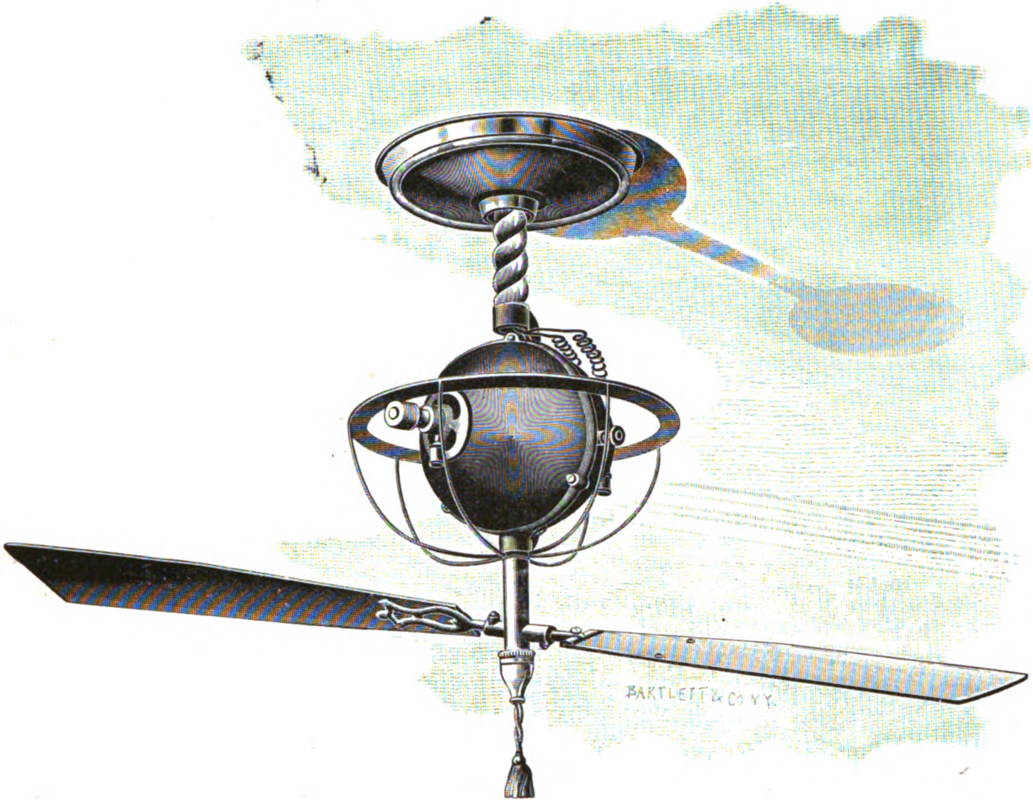
The following notice is issued to the trade by Mr. H B. Cutter:

> This is to advise you that we have opened a New York office at 136 Liberty street, and that Mr. Chas. D. Shain will represent us as selling agent in your vicinity.
>
> Please be kind enough in future to send all orders for our specialties to Mr. Shain, and you may feel satisfied that your wants will be carefully looked after, and the best possible quotations made to you.
>
> Thanking you for past favors, and requesting a continuance of your trade, we are,
>
> Yours very truly,
> THE CUTTER ELECTRICAL AND MFG. COMPANY.

Mr. Shain has also made arrangements with the Eastern Electric Cable Company of Boston and the Lake Girard Mica Mines for exclusive territory in this neighborhood.

The Lundell Ceiling Fan Motor.

We illustrate below an ingenious combination of a big two-blade fan and a small compact motor. The device is so constructed as to depend from any ceiling at the correct distance for the required effect, whether a heavy blast, a gentle breeze, or any gradation between the two extremes is wanted. The blades of the fan are constructed of hard wood and the pitch of them can be changed to suit requirements by loosening the screws which hold them in position and resetting them.



BARTLETT & CO N.Y.

THE LUNDELL CEILING FAN MOTOR.

The method of transforming the motion of the commutator shaft of the motor into a motion at right angles to it, is worked out so cleverly as to obtain an absolutely noiseless result at maximum speed. Upon one end of the motor shaft a small friction wheel is attached. Encircling the motor and resting on this wheel is a thin circular ring plate which receives its motion by friction from the small wheel. This circular ring plate is in turn connected with the fan shaft by four curved metal braces, making a solid and strong construction.

The relation of the speed of the fan to that of the motor thus becomes as one to eight. To operate this outfit only six-tenths of an ampere of current is required, or about the same amount as is required for an ordinary 16 C. P. lamp. The economy in working this outfit, therefore, is readily appreciated. The motor is the invention of Robert Lundell and the outfit is placed on the market by the Interior Conduit and Insulation Company.

H. Ward Leonard & Co.

This company has met with a success in its peculiar line of Bulk Electric Contracting which is most astonishing in view of the general dulness in business during the past year.

The business of the company amounted to $530,000 during its first year, that is '91-'92, and is increasing rapidly both in this city and throughout the country.

Since the first of January the capital of the company has been doubled, the fully paid capital of the company now being $120,000.

As this company has no agencies or affiliations with any manufacturing companies, and uses dynamos, engines and specialties made by all first class makers, it has an exceptional familiarity with all apparatus and methods on the market, and can use them in its work to secure the best possible plant the state of the art will permit of.

Among the important contracts now under construction by this company are the following:

Cayadutta Electric Railway—Bulk contract for complete railway 17⅛ miles long, joining Gloversville, Johnstown and Fonda, New York state.

Broadway Power House—Bulk contract for steam and electric plant for 5,000 lights.

Betz Building, Philadelphia—Bulk contract for steam and electric plant for 4,000 lights.

Broadway Cable Road, 50th Street Power Station—Bulk contract, steam and electric plant for 424 incandescent and 22 arc lights.

Scott & Bowne Building—Bulk electric contract for 1,500 lights.

Cammeyer Building—3,100 lights.

Puck Building—1,000 lights.

New Netherlands Hotel—Ventilating fans, motors, etc.

New York, New Haven and Hartford Railroad Building—1,500 lights.

Hawthorne Apartments—300 lights.

Home Life Insurance Company—1,900 lights, dynamos and engines.

Church Mission House—900 lights.

Johnson Building—Wiring for 70 arc lamps.

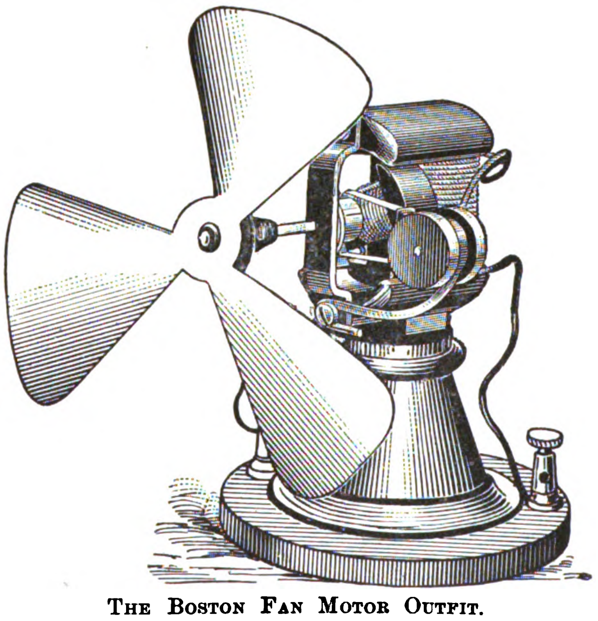
Princeton Inn—Tubing for 232 outlets.

Decker Building—1,200 lights.

The Boston Fan Motor Outfit.

The sudden advent of summer has set everybody perspiring and scurrying round for apparatus that will help in making life bearable during the hot waves which threaten to overtake us. Following the trend of things the makers of electric motors have likewise started up, and are rushing work along to meet the demand that has already set in. One of these firms is the Boston Motor Company, 17 Battery March Street, Boston, whose specialty we herewith illustrate.

We believe we are right in stating that this is the smallest outfit now on the market, and as good as it is small. The makers claim it to be the best and cheapest before the public, and are prepared to guarantee it doing all that is claimed for it. It is scientifically made, of the best material and workmanship. As will be seen, it is mounted on a highly polished pedestal, with nickel plated binding posts, and provided with an adjustable brush regulator. The fan itself is made of polished aluminum, the only one made, and can be operated with any ordinary battery, attaining a high rate of speed with only a single cell. It is just the very thing for a desk, table, office, sick room, or in fact any place where a soft, gentle zephyr-like breeze is required. For these various purposes it has been tried and proved a success, and the demand increases daily. The motor itself is a special favorite with students, amateurs and others for experimental and illustrative purposes, and is now being used in many scholastic institutions throughout the country. It can be run as high as 2,500 revolutions per minute. The very moderate price at which it is sold—fan and motor complete for $1.25—places it within the reach of everybody, and everybody is buying it. The Boston Motor Company will furnish an improved Fuller battery when required that will operate the motor for several days at a trifling cost.



THE BOSTON FAN MOTOR OUTFIT.

This motor gained an award for its many good features at the recent Mechanics' Fair held in Boston.

The Buckeye Lamps.

It affords us no small degree of pleasure to refer to the resumption of lamp manufacturing by the Buckeye Electric Company, and likewise to the fact that the company, according to our best information, are not only regaining old customers but adding new patrons daily to their list. The merits of the Buckeye lamps have been so frequently set forth in our columns that it is needless to say more than that the lamps remain unsurpassed in the qualities that have commended them to the trade and the public. The pure white light that is emitted by the coiled filament is of itself a prepossessing characteristic, and when to this are added the increased light and unimpaired efficiency of the lamp during its life of from 1,000 to 4,000 hours, together with its comparatively low operating cost, it seems to us to fulfil all the requirements demanded by the most exacting user of electric light.

Convention Exhibits Pay.

The small but interesting exhibit of their special line of goods made by the Gould Packing Company of East Cambridge in the ladies' parlor of the Southern Hotel, St. Louis, during the February Convention of the National Electric Light Association has proved to be an unusually profitable exhibit. The various sizes of steam and water packing shown, and the unique substance and finish of the material used, attracted the attention of all the visiting electricians and engineers, with the result that the company is now shipping consignments daily to all parts of the country, from the Atlantic to the Pacific. The fact that the Gould specialty is the original Ring Packing, which was on the market long before any other imitation make, coupled with the continued high quality of stock used, which is the very best, ensures this line of goods greater popularity and a bigger demand among the electrical and engineering fraternities than any other packing now manufactured.

The American Incandescent Lamp.

By a reference to our advertising pages it will be noticed that the "American" incandescent lamps, made by the American Electrical Manufacturing Company of St. Louis, are again on the market. This company, although comparatively new in the field, has established a place for itself, and the "American" lamps are already well known the country over. Business is opening up nicely, and the company looks for a busy summer.

The Logan Storage Battery.

The attention of electricians is being attracted to the Standard Electric Company of Detroit, Mich., which owns the patent rights and is just beginning to turn out Logan Storage Batteries in large quantities.

The claims made by the Standard Company for the Logan battery are most sanguine in view of the many complete failures in the past of storage batteries to perform anticipated work. This company has made a large number of contracts, giving guarantees such as have never before been tendered by storage battery manufacturers.

Mr. J. W. Johnston, the General Manager of the company, has entered into a contract with the Citizens' Street Railway Company of St. Louis for furnishing batteries for three motor street cars. These motor cars are to be placed upon the railway as a test, to demonstrate the utility of storage batteries as a motive power for street railways.

For this reason Mr. Johnston made his proposition on an advertising rather than a commercial basis. The conditions upon which the batteries are placed upon the cars of the Citizens' Railway are that they shall propel the cars sixty or eighty miles per day for one year without cost to the railway company save that of re-charging the battery once in twenty-four hours. At the end of the year if the batteries have demonstrated their utility to the entire satisfaction of Captain McCulloch, superintendent of the company, the Standard Electric Company is to receive $1,000 for each battery. This figure is made very low in order to demonstrate to the world that a successful storage battery has at last been devised.

Mr. Johnston has for his company also contracted with Mr. John Scullin, of St. Louis, to furnish a battery for an owl car for the Union Depot street car line of that city, on equally favorable terms to those given the Citizens' Railway Company. This car is now being constructed in St. Louis, and the battery to propel it is about completed at Detroit.

Contracts have been made by the Standard Electric Company to light the Central Block in Pueblo and the Kaiser Block in St. Louis. The Detroit House of Correction has been lighted, with perfect success, for ten months by this system.

The economy of the battery system is that the steam or other power used to run elevators or other machinery during the day time will also, without extra cost, furnish the power to drive a small dynamo during the day, which will store enough electricity to light the building during the night and drive the machinery also in extraordinary cases.

The Standard Electric Company bases its claims and guarantees upon actual tests made with the Logan Battery at Detroit, Mich., where it has been in constant use in various capacities for twenty-eight months. In that time it has been used for driving small machinery, such as sewing-machines, fans, drills, lathes, riveting machines, for lighting factories and residences, lighting and decorating churches during unusual ceremonies or festivals, operating alarm and fire bells in hotels and factories, connecting the keys with the valves of a large church organ in which the two were separated some two hundred feet, and in propelling a street car.

The features upon which the managers of the Logan Storage Battery place their claims for its superiority over other storage batteries are that the construction of the plates is such that they are practically indestructible; that by no possible usage in charging or discharging, or accident to machinery, or by jarring as on street cars, can the red lead or active material of the plate be shaken from its position, or the plates be short-circuited.

The Standard Company has for twenty-eight months been actively engaged in putting the Logan Storage Battery plates to all manner of possible tests, and after this long time spent in experimenting the company has as yet not had one single plate destroyed or injured.

Their tests have also, they claim, demonstrated the fact that it is possible to take from the battery as high as ninety-seven per cent. of the energy of its charge, and that ninety per cent is a fair average of the power it will discharge.

COMMERCIAL PARAGRAPHS.

As an indication of the phenomenal success achieved by Insullac, the new preparation introduced by the Massachusetts Chemical Company of Boston, it may be stated that after enlarging its factory the entire works are having to run night and day, and even then cannot keep up with the demand. Insullac has made fast friends everywhere, and holds them right along, besides adding new ones daily.

The Boston Braid Company, whose high grade silks for incandescent lamp filaments have proved themselves without a peer and enjoyed almost a monopoly for several years, is now deluged with orders, its manufacturing facilities being taxed to the utmost. Since the lamp business opened up again with so much vim, the Boston Braid Company has been favored with large orders for silks, and the necessity for enlarging its facilities is now under consideration.

That the "Novak" lamp has struck it rich is settled beyond doubt by a record of 20,000 sold in a little more than a week. One salesman is averaging 1,000 lamps sold per diem. In popular phraseology they sell like hot cakes. One plant in Boston is using 800 lamps of this type, and everybody is in love with them.

W. R. Brixey, manufacturer of Day's Kerite Wires and Cables, has contracted to manufacture and lay for the Metropolitan Telephone and Telegraph Company two No. 18 conductor submarine cables, similar to the nine previously furnished, and which are now in service between New York and Jersey City, under the North River. Mr. Brixey has just returned from an extended visit to Chicago, where he has been looking after the preparing of his exhibit which is now completed, being the first wire exhibit in the Electricity Building in readiness.

INCORPORATIONS.

The Waring Electric Company, at Hartford, Conn. Capital stock, $5,000. Incorporators E. D. Robbins, C. T. Robbins and R. H. Robbins, all of Wethersfield. The company is to do all kinds of business connected with the use of electricity, except telegraph, telephone, electric light or power business.

The East End and Sharpsburg Electric Railway Company, at Harrisburg, Pa. Capital stock, $300,000. The officers are: J. R. Davis, New York, president; S. D. Hicks, Edward Fell Lukens, William J. Wagenknight, Charles E. Perkins, Philadelphia.

A charter has been issued at Harrisburg, Pa., to the Philadelphia and Pittsburg Railroad Company. Capital stock, $1,500,000. The road will be forty-five miles long, and run through Clearfield, Cambria, Jefferson, Indiana and Armstrong from Mehaffey, Clearfield County, Pa., to a point near Kittanning, in Armstrong County. The president is William J. Wagenknight, of Philadelphia, and the directors are S. H. Hicks, C. F. Lukens, Theodore P. Farrell, F. S. Purnance and Charles E. Perkins, all of Philadelphia, and Robert C. Belleville, of Trenton, N. J.

A company has been formed at Hoosic Falls, N. Y., to build an electric railway at that place, and to be incorporated under the general railroad law of the State as the Hoosic Railroad Company, with a capital stock of $60,000. C. B. Story, through whose efforts the success of the project is assured, will be one of the company's directors and will also act as superintendent of the road.

The Dubuque Light and Traction Company, successors to the Dubuque Light and Power Company, Dubuque, Iowa. Capital stock, $600,000. The officers of the new company are as follows: President, G. H. Wheeler, Chicago; vice-president, W. J. Ballard, Chicago; secretary and treasurer, E. W. Duncan, Dubuque.

The Post-Glover Electric Company, Cincinnati. Capital stock, $50,000.

The Camden, Gloucester and Woodbury Electric Railroad Company, at Trenton, N. J. Capital stock, $600,000. Incorporators: William J. Thompson, Henry M. Harley and Abraham Townsend, of Gloucester City; Senator George A. Barker, of Woodbury; Ex-Sheriff David Baird, Sheriff Henry J. West, J. Willard Morgan and Thomas P. Curley, of Camden, and Gustavus A. Miller, of Philadelphia. The road is to be in operation by July 1. The electric power is to be supplied from a station at Gloucester.

The Franklinville Electric Light Company, Franklinville, N. Y. Capital stock, $12,000. Incorporators: S. A. Spring, W. H. Ferris, Dr. H. D. Walker, E. E. McNall, A. and G. E. Spring, A.W. Kingsley, J. K. Button, Jr., and J. C. Bowen.

The incorporators of the Buffalo, Tonawanda and Sanborn Electric Railroad, to run from North Tonawanda to Sanborn, are Wilmer Brown, Louis F. W. Arend, Martin F. Meyers, Thomas S. Belden, Lee R. Sanborn, Fred W. Strasburg, William O. Huggins, Harvey Hoag, John T. Witkopp, Edward G. Riesterer, Lewis T. Payne, Herbert P. Bissell, John H. Bissell, John H. Pardee, Christian F. Goerss and Frank T. Brundage.

The Jenney Electric Light and Power Company of Peoria, Ill., has announced an increase of capital stock to $200,000. In addition to this the name of the corporation has been changed to the Peoria General Electric Company.

The Dansville Electric Railway Company, for the construction of an electric road three miles in length in Dansville, Livingston County, N. Y. Capital stock, $50,000. Among the directors are S. N. Blake, of Elmira; D. O. Batterson, Charles H. Rowe, William Kramer and James E. Crisfield, of Dansville.

The Townsend Gas and Electric Company, at Seattle, Wash. Capital stock, $150.000. Incorporators: Frank A. Bartlett, John Lillie, E. B. Downing, N. J. Grambs and S. Z. Mitchell. The company will engage in the business of furnishing public and private light, heat and power.

The Grand Island Rapid Transit, Light and Power Company, Grand Island, Neb. Capital stock. $250,000. Incorporators: A. S. Vest, Chas. G. Ryan, E. G. Stolley, W. H. Thompson, of Grand Island; Moses Stern, Elmer Sommers and G. R. Furr, of Denver, Col. An electric plant will be established by the company and a street railway constructed by it.

The Sheridan Electric Company, Sheridan, Wyo. Capital stock, $30,000. Trustees: G. C. Smith, A. M. Holbert, L. H. Brooks, J. P. Robinson, B. F. Perkins, L. Casper and E. E. Lonabaugh. The company was organized to build a street railway and for manufacturing purposes.

The Livingston, Independence and Cooke City Telephone Company, to build a telephone line from Livingston to Boulder and Cooke City, Mont., and other points. Capital stock, $10,000. Incorporators: W. J. Anderson, George L. Carey, John R. King, F. A. Krieger, A. W. Miles, Herman Orschel and James S. Thompson, all of Livingston, Mont.

The Western Electric Power and Light Company of Topeka and El Reno, Oklahoma. Capital stock, $50,000. Directors: A. F. Chesney, E. E. Chesney, Joseph Reed, O. M. Chesney and Wm. Dignon of Topeka; Charles Stackhouse of Osage City.

The Wilkes-Barre and East Side Railway Company, Wilkes-Barre, Pa. Capital stock, $50,000. Directors: John Graham, G. R. Bedford, W. S. Biddle, W. G. Eno and H. H. Welles, Jr. The company is chartered to build an electric line in Wilkes Barre.

The D'Unger Electrical Telephone Manufacturing Company, Chicago. Capital stock, $100.000. Incorporators: J. F. Greene. W. D. Johnston and H. S. Folger.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MAY 9, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

496,896. Contact for Underground Electric Railways. William Q. Prewitt, Lexington, Ky. Filed May 19, 1892.

497,024. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Original application filed June 21, 1886. Divided and application filed June 20, 1889. Again divided and this application filed May 14, 1890.

497,025. Overhead Electric Railway. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Original application filed Sept. 23, 1886. Divided and application filed June 1, 1887. Again divided and this application filed Sept. 18, 1890.

497,061. Electric-Railway Switch. Edward F. Stone, Hyde Park, Mass. Filed Feb. 1, 1890.

497,293. Trolley-Wire Support. Henry A. Hamlin, Minneapolis, Minn. Filed June 18, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

496,882. Electric-Arc Lamp. Martin Kruegar, Chicago, Ill. Filed Oct. 5, 1891.

497,038. Electric Lamp. John Waring, Manchester, assignor to the Waring Electric Company, Hartford, Conn. Filed Jan. 4, 1893.

497,104. Automatic Switch for Mast-Arms. William A. Turbayne, Detroit, Mich. Filed Nov. 5, 1892.

497,200. Electric-Lamp Support. James Nortney and Frank Schefold, New Albany, Ind. Filed Dec. 23, 1892.

497,251. Coupling for Electric-Light and Gas Fixtures. George Peeples, Philadelphia, Pa., assignor to the Thackara Manufacturing Company of Pennsylvania. Filed Nov. 19, 1892.

DYNAMOS AND MOTORS.

497,110. Multiphase-Electric Motor. Paul A. N. Winand and Carl O. C. Billberg, Philadelphia, Pa. Filed March 22, 1892.

497,113. Transformer-Motor. Otto T. Blathy, Buda-Pesth, Austria-Hungary. Filed March 24, 1891.

497,123. Commutator for Electric Generators or Motors. Midbury W. Hassan, Rochester, N. Y. Filed March 16, 1892.

497,144. Pedal-Switch for Electric Motors. Levi Teal, Philadelphia, Pa., assignor to the S. S. White Dental Manufacturing Company, same place. Filed Jan. 16, 1893.

BATTERIES.

496,878. Galvanic Battery. Charles W. Holtzer, Brookline, Mass. Filed Nov. 14, 1891.

TELEPHONE AND TELEGRAPH APPARATUS.

496,859. Transfer System for Telephone-Switchboards, Emery A. Clark, Sioux City, Iowa. Filed June 24, 1892.

MEASURING INSTRUMENTS.

496,871. Electric Meter. Oscar Ericsson, Sioux Falls, S. D. Filed May 6, 1892.

496,962. Dynamometer. Joseph A. Wade and John Cherry, Hornsea, England. Filed Nov. 9. 1891.

496,963. Dynamometer. Joseph A. Wade and John Cherry, Hornsea, England. Filed Aug. 1, 1892.

SWITCHBOARDS, ETC.

496,901. Switchboard for Electric Circuits. Albert L. Rohrer, Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed June 20, 1892.

496,904. Multiple-Switchboard Apparatus. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb. 7, 1890.

496,905. Multiple-Switchboard System. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 1, 1890.

496,906. Multiple-Switchboard Testing Apparatus. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 1, 1890.

496,907. Testing Apparatus for Multiple-Switchboard Systems. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 24, 1890.

MISCELLANEOUS.

496,863. Apparatus for Electrolysis of Salt. Thomas Craney, Bay City, Mich. Filed Jan. 4, 1892.

496,864. Electrolytic Apparatus Thomas Craney, Bay City, Mich. Filed April 7, 1892.

496,865. Electrolytic Apparatus. Thomas Craney, Bay City, Mich. Filed Aug. 18, 1892.

496,918. Safety Connection for Induction-Coil Systems. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Oct. 8, 1888.

496,945. Electric Traveling Crane. William H. Morgan, Alliance, Ohio. Filed June 13, 1892.

497,004. Animal Trap. John W. Glover and Edmond C. Glover, Randall, Ark. Filed Nov. 30, 1892.

497,117. Magnetic-Ore Separator. Charles G. Buchanan, New York, N. Y. Filed May 17, 1892.

497,120. Electrical Circuit. Charles E. Chinnock, Brooklyn, N. Y. Filed Dec. 17, 1891.

497,129. Electroplating Apparatus. Albert R. Reams, Elmira, Cal. Filed Oct. 15, 1892.

497,197. Portable Electric Abrading Device. Aaron J. Nellis, Pittsburg, Pa. Filed Dec. 12, 1892.

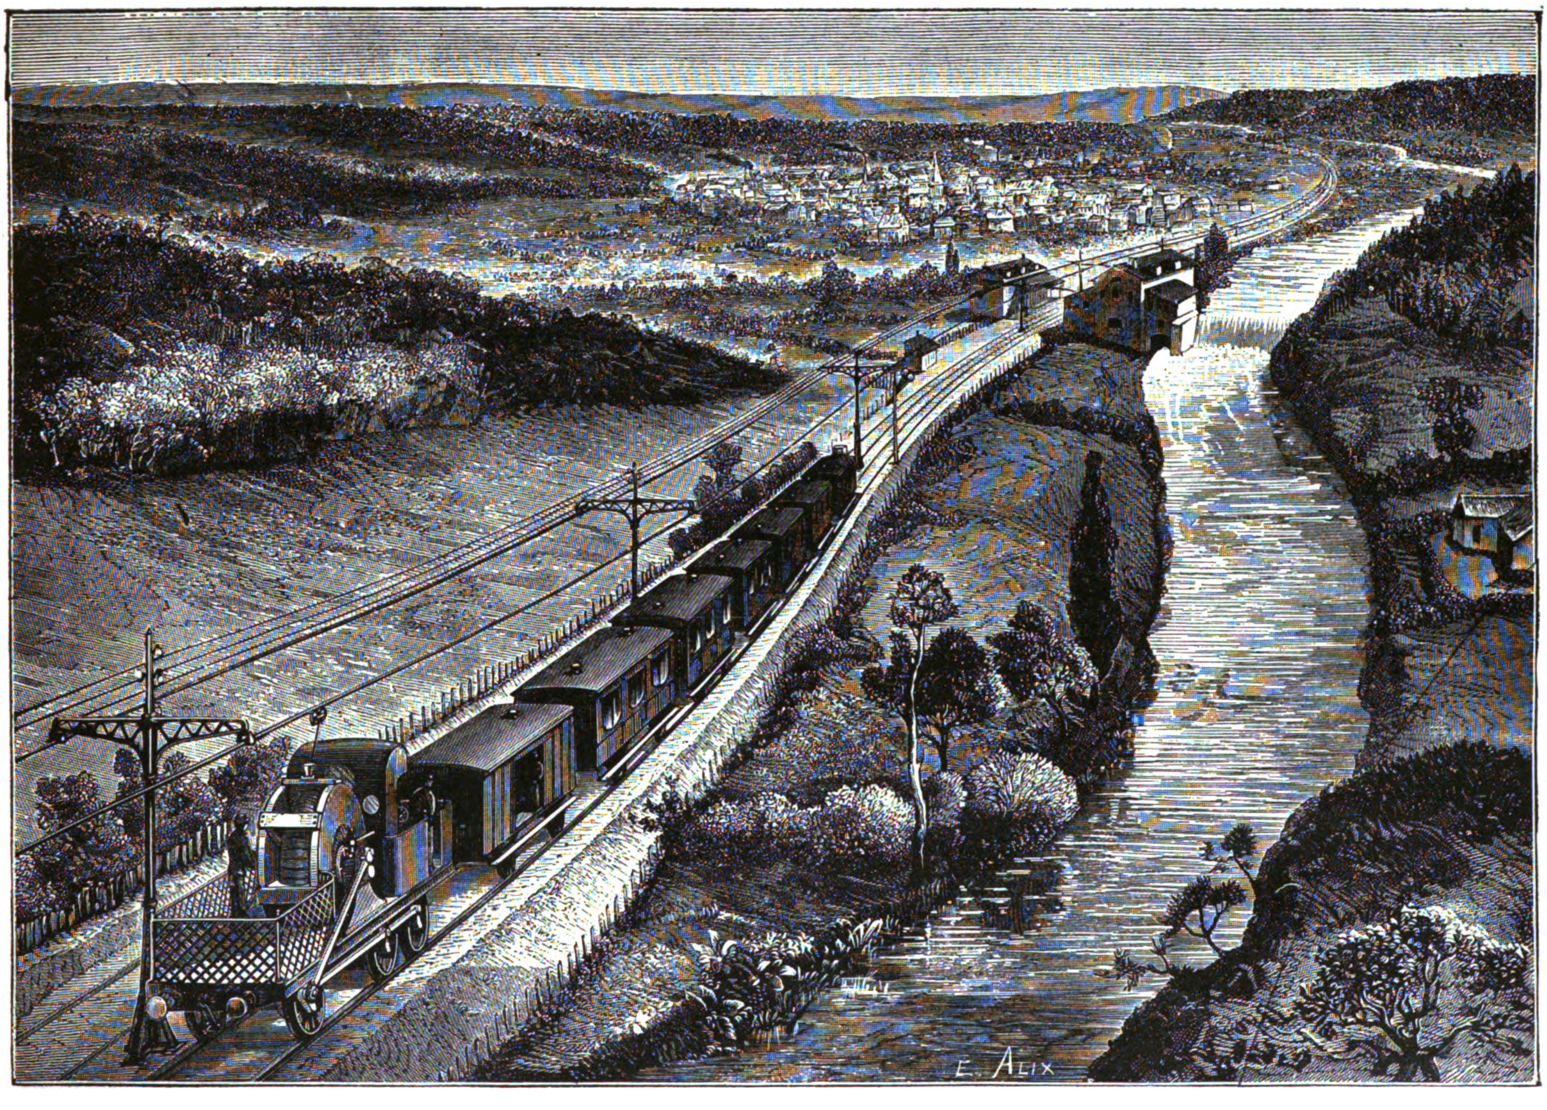
497,203. Electric Time Stock-Feeder. Herbert S. Page, Medford, and Livy Spear, Boston, assignors to Edmund D. Spear, Boston, Mass. Filed Oct. 12, 1892.

497,263. Electric Cigar-Lighter. William P. Carstarphen, Jr., Denver, Col., assignor of two-thirds to James E. Gregg, same place, and Richard W. Webb, Santa Fe, New Mexico. Filed Nov. 7, 1892.

497,281. Signal-Transmitting Apparatus. Morris Martin, Malden, Mass., assignor to the United States Electric Fire Signal Company, Portland, Me. Filed Aug. 20, 1892.

ELECTRICITY.

VOL. IV. NEW YORK. MAY 24, 1893. CHICAGO. No. 19



AN UNDERRUNNING TROLLEY OF 1884. (SEE PAGE 255.)

Atomic and Molecular Motions.

III.

BY A. E. DOLBEAR.

If the movements that cause such waves were of an oscillatory, or free path, or translatorial motions of the atoms and molecules, there could be no such thing as definite and continuous wave lengths such as we find, for an atom moving thus would be going now in this direction, now in that, with varying velocities and distances, and if waves were formed at all they would be of all imaginable lengths, and what we call spectrum analysis would be impossible. But the vibrations that set up such waves as we see and measure, we call heat. If the number of vibrations does not equal four hundred million of millions per second we cannot see them because the eye is not adapted to perceive longer waves, but with other devices longer waves can be found. Photography has shown us the existence of waves very much longer, and Prof. Langley has measured their wave length with his bolometer, so we are certain of their existence. Not very long ago it was thought that there were three different kinds of waves—a hot body gave out heat waves, light waves, and atomic or chemical waves, but it has been found for certain that there are no such distinctions. Every wave, long or short, will heat matter, and every kind of a wave can do chemical work; it simply depends upon what kind of a substance it falls on. So these terms have dropped out of use. Indeed it has been found that the same ray that can heat matter or do photographic work may excite vision if it falls upon the eye, so that the term *light* is slowly dropping out of use as belonging anywhere except in the physiology of vision, and ether waves of all wave lengths are called simply *ether waves*.

It has been discovered that such waves as an atom can produce when it vibrates can make the atom vibrate when it falls upon it, just as a sounding tuning fork can make another fork sound if the time of vibration of the latter is the same as that of the former. This is called sympathetic vibration, a property that belongs to atoms as well as to bigger bodies. Every atom, then, that has any temperature is setting up waves in the ether, and when these waves fall upon other matter having similar rate of vibration, the latter are thrown into vibration—that is to say, they are heated, for heating consists in giving vibratory motion to the atoms of a body. Such exchange of motion is going on all the time between masses of matter of all degrees of temperature, and in physics is called Provost's Law of Exchanges. If the body receives a wave having greater energy than the wave itself sets up, then it becomes hotter, and vice versa. This is the reason the sun heats the earth. The latter is a cooler body, but it sends back waves to the sun, though such waves are not so energetic as those it receives. Heat, then, is the true vibratory motion of atoms and molecules by which they are able to set up waves in the ether, as translatory motion cannot do, and light or ether waves result from such vibratory motions; there has been a transformation of one kind of motion in one substance, matter, into another kind of motion in another kind of substance, the ether. As such kind of motion in matter involves a kind of energy called heat energy, by which it is able to do work in the sense in which that term is used in the arts, so when the motion is transformed into a warm motion in the ether it still possesses the same energy it had, and it is now called *radiant energy*. As the amount of energy or the ability to do work is not altered by the transformation, whatever it may be, we have a general statement or doctrine, now well established in science, called the conservation of energy, which means that the amount of energy in the universe is constant, and does not suffer change in any degree in the endless series of phenomena which the energy produces.

The common properties of a magnet by which it attracts iron, sets itself in a north and south position when free to do so, has a mechanical choice of position with reference to other magnets, and induces currents of electricity in conductors which are moved in its neighborhood These are well known, and these properties are of such a high degree of importance to our civilization that one may reflect upon how much of civilization of to-day is dependent upon the property of that element iron. There would be no mariner's compass, no telegraph, telephones, or electric lights. When men began to try to explain this action of a magnet, they imagined fluids for the sake of a hypothesis. But a fluid that should act as magnetism acts would be as wonderful as the magnet; and at any rate would be entirely unlike any fluids we have any knowledge of. Seeing that the action of a magnet takes place freely in the most perfect vacuum we can make, it is plain that ordinary matter is not essential to it. The space about a magnet, within which such magnetic phenomena take place, is called its magnetic field. It extends indefinitely from it, and may be said to be as extensive as is the universe, for its strength when measured is found to vary inversely as the square of the distance.

Suppose this object to be a straight bar magnet with its poles and field: if there were a number of delicately-poised magnetic needles in this room, every one would be disturbed from its position each time I changed the position of this, only the nearer ones would suffer more disturbance than those more remote. That would signify that the magnetic field of the magnet extended through this room, and if means were properly arranged it would be possible to learn from the movements of magnets hundreds of feet from here changes in the position of a magnet in this room. If one can think of a magnet as affecting the ether of space in such a way as to produce it in a condition of stress, it may be easier to understand how it is possible for it to affect another body at a distance, for if the ether that surrounds a body is thrown into a stress in any way, one would expect some sort of an effect to be produced upon other bodies by it. Especially sensitive would be another body which had its own magnetic field, which is the case under consideration. When the field is disturbed, the body must change its position. Imagine, then, this magnet with its north pole here and its field stretching out indefinitely in each direction. It is to be supposed it extends to the moon—indeed to the stars and beyond, if there be a beyond. Now let us reverse the position of the ends of the magnet, and consider what has taken place. The magnetic field about it will have been quite reversed in direction, and all needles in its neighborhood would have indicated the change. The field then as a whole would be changed, but the whole means the whole of space. But the change in the field brought about by reversing the position of the poles will not instantly be felt throughout space. It takes time for a magnetic field to travel in the ether. It has indeed been found experimentally that a change in a magnetic field travels with the same velocity as the common waves in the ether which we call light; namely, 186,000 miles a second; so if I should reverse the ends of the magnet at the rate of once per second, I should set up an ether wave that would be 186,000 miles long. If twice a second, it would be half as long, and if I could change it 186.000 times a second it would be only one mile long. Every change in the form of a magnet causes a corresponding change in its whole field. Wind a few turns of insulated wire about the bend of a U magnet, and connect it in circuit with a distant telephone. These strike the magnet so it will ring, giving out a sound with a definite pitch. The sound will be heard with great distinctness in the telephone. If another similar magnet be held near to the first magnet, and struck so as to sound, the pitch of the second magnet will be heard in the circuit of the first magnet, which shows that magnetic waves were formed in the ether whose length must be equal to 186,000 divided by the number of vibrations of the magnet per second. The experiment is interesting as it helps to make clearer the underlying factors which probably set up waves we call light waves.

When an ordinary magnet is broken into two parts, each part possesses the same polar qualities, and this division and sub division can be carried on indefinitely until one comes down to molecular magnitudes. This has led physicists to the conclusion that the atoms of iron and certain others of the elements are magnetic, with the fair probability that such is the case with the atoms of all the elements. But to suppose that an atom of any sort is a magnet is to consider it as having poles and an individual magnetic field as extensive as any magnetic field. When such atoms are so arranged in a solid that all their similar poles face one way, we have what constitutes a magnet; indeed, such an one would be the strongest possible magnet, for it is now generally conceded that what we call magnetism, or rather a magnetic field, is due solely to the arrangement of the atoms of the magnet. If these atoms are not similarly arranged, but are in magnetic disorder, they naturally destroy each other's fields, so one would not discover the presence of magnetism in such a body.

Suppose, therefore, we have to do with a single atom of iron—that it is a magnet by virtue of its inherent quality. It has its poles and its magnetic field, as extensive as any field, that is, it extends throughout space. If such a magnet should be made to vibrate, by impact or in any other way, its magnetic field would be made to change in a corresponding way and waves would be propagated with the speed of light in every direction about it. How many times per second can such a body vibrate per second? The number of vibrations a body will make depend upon its size, its elasticity and its density.

The smaller it is the more rapid these are. If the size be in the neighborhood of the one-fifty millionth of an inch, and its elasticity such as is possessed by the ether, it will vibrate hundreds of millions of millions of times. Its field will be varied as often, and the length of such magnetic waves produced will be such a small fraction of an inch as are those which we call light; and there is every reason to believe if one could make a magnet of any size to vibrate so many times per second it would become luminous, we should say it gave out light, though its temperature were that of a freezing body.

I have already mentioned the number of vibrations a heated body must make in order to be luminous, and also the mechanical conditions of impact which are antecedent to such heat phenomena. If you will add to those conditions the conception of atoms as individual magnets, each with its own magnetic field, you will be able to understand the expression, now beginning to be frequently heard, "Light is an electro-magnetic phenomenon."

Lastly, a current of electricity, however produced, is capable of bringing about the same kind of magnetic phenomena as are produced by what we call a permanent magnet. A conductor with a current of electricity in it possesses a magnetic field about it and concentric with it. It extends indefinitely distant from it, following the same law.

Any change in the strength of this current brings about a corresponding change in the field of the current and is propagated outwards with the velocity of light. When such a conductor is coiled into a ring, the ring possesses all the qualities of a magnet. If free to move it will set itself so as to face north and south. It will react upon a magnet in precisely the same manner as if it were a magnet, and all this without there being any iron or steel in the neighborhood. As the poles of the ring depend upon which way the current is going in it, it follows that if one could conceive of atoms as being conducing rings with permanent currents of electricity in them, he would have a conception that would explain the phenomena of heat, of light and of magnetism. Such a conception of the cause of magnetism was proposed by Ampere about seventy years ago, and it has been growing in probability, especially since renewed attention has been given to electrical and magnetic phenomena.

The vortex ring theory of matter lends itself easily to this idea, for it assumes that atoms are revolving rings of ether in the ether—that is, they are made of ether and exist in it as smoke rings exist in the air. If it shall at last be proved, as it may be, that a whirl of a certain kind in the ether constitutes what we call a current of electricity, and is embodied in what we call matter, we shall then have reduced to various forms of motion all the various phenomena which are traceable to matter, including all its properties, for it has already been shown that what we call electricity may be explained as the results of certain kinds of motion, and as the various kinds of motion in matter are transformable, directly or indirectly, into kinds of motion in the ether, it leaves us with the conclusion that, after all, the factors in all phenomena are the ether and motion, and that what we call matter is at last only a particular kind of motion in the same illimitable and mysterious substance, the ether.

The Official Badge

Adopted by the American Institute of Electrical Engineers.

The official badge herewith illustrated embodies the following characteristics:

Franklin's kite, which demonstrated the identity between lightning and electricity, and represents static electricity. It is a recognition of America's first electrician and philosopher, Benjamin Franklin.

A diagrammatic representation of Wheatstone's bridge, one of the most important pieces of electrical testing apparatus.

The galvanometer, another equally important piece of testing apparatus and which represents Magnetism and Induction.

The amber of which the galvanometer is made represents the first conception of electricity, dating back to 600 years B. C., when Thales, the Greek philosopher, recorded the fact that amber when rubbed attracted light particles to it; and the Greeks worshipped it, believing the gods had endowed it with life and that it possessed a soul.

In 1600 A. D., Dr. Gilbert, court physician to Queen Elizabeth, coined the work electricity from the word elektron, the Greek name for amber.

A. I. E. E. represent the initials of the American Institute of Electrical Engineers.

$C = \frac{E}{R}$ represents Ohm's law—a fundamental law in electrical work.

The pin is made of white enamel with the lettering and front portions in 18 karat gold and the back in 14 karat gold. Apply to the secretary, Ralph W. Pope, 12 W. 31st street, New York.

SOCIETY NEWS.

American Institute of Electrical Engineers.

Annual Meeting and Election.

The general meeting of the Institute for the reception of reports and election of officers was held on Tuesday afternoon. After hearing the reports the meeting adjourned pro tem. While the ballots, which were cast under the new system by mail, were being counted, the large number of candidates which this system allows made the vote somewhat difficult to count, but after over two hours' work the tellers announced the following ticket elected: Edwin J. Houston, President; H. Ward Leonard, P. B. Delaney and William Wallace, Vice-Presidents; Ralph W. Pope, Secretary; Geo. M. Phelps, Treasurer. The new members on the Board of Managers are Charles Hewitt, W. J. Hammer, Horace J. Ryan and J. J. Carty.

After short addresses by President Houston and Ex-President Sprague the members assembled at THE ARENA, where the evening was pleasantly spent in appeasing the inner man and listening to the flow of wit and eloquence responsive to the numerous toasts.

On Wednesday the reading of papers and discussions took place as announced except the paper on "Electrical Resonance" by Dr. Pupin, which was postponed until 4 o'clock in order to permit an adjournment to Columbia College, where apparatus was available to illustrate the experiments which the paper described.

In the evening a number of the members assembled again at Columbia College at the invitation of the New York Electrical Society to listen to a lecture by Dr. William J. Morton on "A Brief Glance at Electricity in Medicine," an abstract of which will be found elsewhere.

On Thursday afternoon a visit was paid to the new works of the Crocker-Wheeler Company at Ampere, N. J., to inspect its plant, which is a departure from the usual practice of running shafting. The company provided special cars for this trip, and those members who were able to accept this invitation enjoyed an extremely pleasant and instructive tour of inspection.

The officers of the company placed themselves and the factory at the disposal of the visitors and every department was thoroughly investigated by them. The chief feature of the plant is the almost entire absence of shafting and belting, and the substitution of copper conductors in their place. The machines are nearly all of special design in which the motive power is supplied by electric motors which are built in the machines and connected directly to the moving parts without the use of belts wherever possible.

The usual noise of a machine shop is almost entirely lacking in this case, and the saving in power over what would be necessary to constantly run lines of shafting must amount to an important item, which was generally remarked among the visitors.

New York Electrical Society.

The last meeting of the Society for the season was held on Wednesday last, at which Dr. William J. Morton delivered a lecture on "A Brief Glance at Electricity in Medicine." At the close of the lecture one hundred tickets to the illustrated lecture "Urania" were kindly placed at the disposal of the Society in addition to an invitation to look into the details of apparatus by means of which the wonderful scenic effects are produced.

At the close of the lecture on Friday evening the stage of the Music Hall was overrun by the members of the Society, and the ingenious mechanism used in this production was examined and explained.

National Electric Light Association.

The lecture delivered by Mr. Tesla before the St. Louis Convention of the N. E. L. A. is shortly to be printed in book form in the Transactions of the Association, and is considered the most valuable work ever published by it. The lecture was an experimental one on the subject of high frequency and high potential alternate currents, and the manuscript is illustrated by forty-six illustrations of the experiments performed.

The Under-running Trolley.

Regarding the date of the appearance of the under-running trolley, which we have had occasion to refer to before, we reproduce this week in our Frontispiece an illustration of such a device, taken from *La Lumière Électrique* of March 14, 1885. The cut is included in a series of articles by MM. Deprez and Leblanc, reviewing the status of electric railway work up to the close of the year 1884. The present illustration is but one of a number which clearly show the under-running trolley with spring adjustment. The latest installation of this character is described in these articles as having been made in the early part of 1884 by the house of Siemens, between Frankfort and Offenbach, and a number of other roads in operation previous to this date had made use of the same device.

In view of these public uses of the kind of trolley described, it appears difficult to understand how this same apparatus can be considered an American invention in 1887 and 1888, as claimed by the Thomson-Houston Company in their impending patent infringement suit.

Electrical Experiments on the Erie Canal.

The Superintendent of the State Department of Public Works has issued an order providing that all persons desirous of experimenting with electricity or other power for propelling boats on the canal must have their applications for such privilege on file in his department by June 5. This order was issued in pursuance of a law passed by the last Legislature authorizing the Superintendent to designate certain sections of the Erie Canal on which experiments may be made for testing the efficiency of such devices as may be offered for improving by electrical or other means the present system of canal towage, such experiments to be conducted at the expense of the parties making them.

Proposals Wanted.

Sealed proposals will be received for an electric light plant for the Masonic Temple, Philadelphia, until 3 P. M. June 10, 1893. Specifications and drawings will be delivered to bidders between the hours of 9 A. M. and 3 P. M. May 29, 1893. Security will be required before specifications and drawings are delivered. For particulars address Dr. W. A. Drysdale, Consulting Engineer, 20 Hale Building, Philadelphia.

Personal.

Mr. W. S. Barstow, General Superintendent of the Brooklyn Edison Company, delivered an interesting address before the Brooklyn Institute of Arts and Sciences on Friday evening last, presenting briefly his conclusions in regard to European lighting practice as compared with our own.

The Green Trolley Patents.

Suit Begun in Ohio.

A suit has been begun in the United States Circuit Court at Cincinnati, in the name of Oliver S. Kelly and the General Electric Company against the Springfield (O.) Railway Company and its officers, for infringement of the Green trolley patents, purchased a few months ago by the General Electric Company.

A Historic Group.

The Men Who Established the Claims of Henry Goebel

And Put an End to the Monopoly of the Electric Trust.

WILLIAM C. WITTER.

William Clitus Witter is a descendant of the Witter, Bingham, Bass and Waldo families, who were among the earliest settlers in New England. He was born November 13, 1842, in Willimantic, Conn. His academic studies were pursued at Woodstock, at Bacon Academy, Colchester, Conn., and at the Marion Collegiate Institute, at Marion, New York. He entered Brown University in the fall of 1861.

In 1862 he served for three months with a majority of his classmates as a Union soldier in Company K of the Tenth Rhode Island Regiment, returning in time to proceed with the studies of the sophomore year. In the summer of 1863 he again enlisted, and served six weeks in the Union army as non-commissioned officer. Subsequently entering Yale College as Junior, he was graduated in 1865, and shortly after entered the Columbia College Law School. Two years later he presented himself, prior to graduation, for examination before the Supreme Court, and was successful. Mr. Evarts offered him a place in the office of Evarts, Southmayd & Choate, where he remained for two years. For ten years thereafter he was associated with George Gifford, Esq., in a large and varied practice in the United States Courts in causes dealing with patents, copyrights and trademarks. While with Mr. Gifford he was appointed by the Court a United States Examiner in Equity. In 1879 a partnership was formed with Mr. Causten Browne, under the name of Browne & Witter, afterwards Browne, Witter & Kenyon, and now Witter & Kenyon.

WILLIAM H. KENYON.

Wm. Houston Kenyon is of Scotch parentage, and was born in Hartford, Conn., January 5, 1856. He went to the Old South School in Hartford, and from there to the Hancock Grammar School in Philadelphia, and later to the Central High School of that city. He finally entered the College of the City of New York, and was graduated in 1876, receiving the degrees of B. A. and M. A. in course. On graduating, he held the Third Honorary Oration, and was appointed tutor in Latin at the college, and continued there for four years. Meanwhile he attended the Columbia Law School, and was graduated in 1879.

Selecting patent law as a specialty Mr. Kenyon became associated with Causten Browne, of Boston, and Wm. C. Witter, of New York, in 1880; five years later the firm became Browne, Witter & Kenyon, and in 1887 Witter & Kenyon. The firm now consists of Wm. C. Witter, Wm. H. Kenyon, Alan D. Kenyon and Robert N. Kenyon. It has been engaged in many of the important patent cases of the last decade—with the telephone cases in the early days, with the Brush Arc Lamp and Dynamo Cases, the Brush Storage Battery and the Edison Incandescent Lamp Patents. Through this firm a new law as to design patents was drafted, argued, briefed through Congress, and finally approved on the 5th of February, 1887.

LOUIS D. BRANDEIS.

Mr. Louis D. Brandeis, the Boston counsel of the Beacon Company, was born in Kentucky thirty-six years ago. He was educated at Harvard, and was graduated from the Law School in 1877. After residing in St. Louis for one year, he returned to Boston and began the practice of law in 1879. He built up a lucrative business, and is a leading member of the Massachusetts bar. He is Eastern counsel for the Wisconsin Central Railroad, and has appeared frequently of late in the interests of stockholders against the directors of the New York and New England Railroad. He has been retained as counsel for the Westinghouse Electric Company in the case of conspiracy against the General Electric Company, and is likewise counsel for the Milford and Hopedale Railroad in its suit with the Brush Electric Company on the storage battery question. He enjoys a most enviable position among his legal brethren and in Boston society.

A. S. FOWLER.

Mr. A. S. Fowler was born in Washington, D. C., in April, 1857. He grew up in Washington, and studied civil and mechanical engineering at the Rensselaer Polytechnic Institute, Troy, N. Y., and was graduated in the class of 1878. He practised for a season, and for a year or so was engaged in mining in Colorado. Then he returned to Washington and passed a competitive examination for examiner in the Patent Office, and for nearly four years was in the Electrical division. In 1885 he resigned, and took up the practice of patent law in New York City. Early in 1888 he removed to St. Louis, where he has since made a specialty of patent law cases.

Mr. Fowler is at present interested as counsel for plaintiff in the suit of the Electric Railway Company vs. Lindell Railway Company. As a patent lawyer, and especially on subjects connected with electricity, Mr. Fowler is regarded as the peer of any man in the West.

ELMER B. ADAMS.

Judge Elmer B. Adams was born in Vermont fifty years ago. He was educated at Harvard University, and completed his course at the college Law School, being graduated in 1865. He at once settled in St. Louis, where he has resided continuously ever since. From 1879 to 1885 he was a Judge of the St. Louis Circuit Court. Upon retiring from the bench he resumed the practice of law. He is regarded as one of the ripest lawyers at the St. Louis bar, and his firm (Boyle & Adams) has doubtless the largest practice and the management of more large cases than any other firm in that city. Judge Adams's contribution to the overthrow of monopoly in the case against the Columbia Incandescent Lamp Company was powerful and effective.

HENRY S. KALISKE.

To Mr. Henry S. Kaliske is due, perhaps, more than to any other individual member of this group, the development of the Goebel defense into a winning case. Mr. Kaliske's quick perception of the strong points in the case, his readiness to spend a large sum of money to back his judgment, will not be forgotten.

He was born in New York City in 1862, was educated in the public schools, and when yet considerably under twenty began his commercial career in the leather business. He was one of the original incorporators of the Beacon Vacuum Pump and Electrical Company, and has been from the beginning the manager and a member of the Board of Directors. Though a young man, Mr. Kaliske has already achieved success. He still retains an interest in a very profitable leather business. His push and energy have brought him to the front, and he is recognized as a man of sound business judgment.

JACOB HEILBORN.

Mr. Jacob Heilborn, President of the Beacon Company, is a Boston boy, born in that city thirty-seven years ago. He received his education at the Brimmer School, and afterwards went into the shoe business, with which he is still identified, being Boston representative of Henry Stern & Company, New Orleans, one of the leading firms of the South. Mr. Heilborn is noted for his many fine social qualities, being deservedly popular with a wide circle of acquaintance. At his office or at his home he always makes his visitors welcome, and strangers having business with Mr. Heilborn are sure to be favorably impressed with his pleasant manner.

J. H. RHOTEHAMEL.

Mr. J. H. Rhotehamel, President of the Columbia Incandescant Lamp Company, was born in 1857, in Miami County, Ohio. He was educated in the public schools, and afterwards took a partial course at Antioch College, Yellow Springs, Ohio. Subsequently he taught school for a few terms, and speculated some in real estate.

He went to St. Louis in 1889 and organized the Columbia Company. That Mr. Rhotehamel is a successful business man and has built up a splendid trade for his company is well known.

When the Beacon case was finally decided adversely, all the other lamp manufacturers save Mr. Rhotehamel considered any further legal action to be hopeless. The general sentiment in the trade was that, whatever the merits of Goebel's claims, it would never be possible to win on them. Mr. Rhotehamel thought differently. He was a close listener at the proceedings in Boston, knew the weak points in the evidence and what was needed to make a complete and unanswerable argument in favor of Goebel's claim to precedence.

He wisely engaged the same counsel who had made the splendid fight for the Beacon Company, and then, against the judgment of nearly every one in the business, set to work to gather further evidence. His faith never weakened, and by his persistence and courage he has performed a real service to the entire fraternity.

The names of President Rhotehamel and the Columbia Company must be inseparably connected with the overthrow of the unjust and arrogant monopoly of the General Electric Company.

EDWARD E. CARY.

Mr. Edward E. Cary has been for some time the Superintendent of the Lamp Department of the Beacon Company. He is the youngest man in the group, being twenty-eight years of age. He was graduated from the Brooklyn Collegiate and Polytechnic Institute, after which he had a valuable experience as assistant in the laboratory of Mr. Edward Weston, and subsequently was with the Sawyer-Man Company. Mr. Cary's testimony in the Beacon case showed a wide fund of information and a thorough knowledge of the art.

FRANKLIN LEONARD POPE.

Mr. Pope was born in Great Barrington, Mass., on December 2, 1840. He was educated in his native town, and in 1857 became a telegraph operator, and in 1862 was made assistant engineer of the American Telegraph Company.

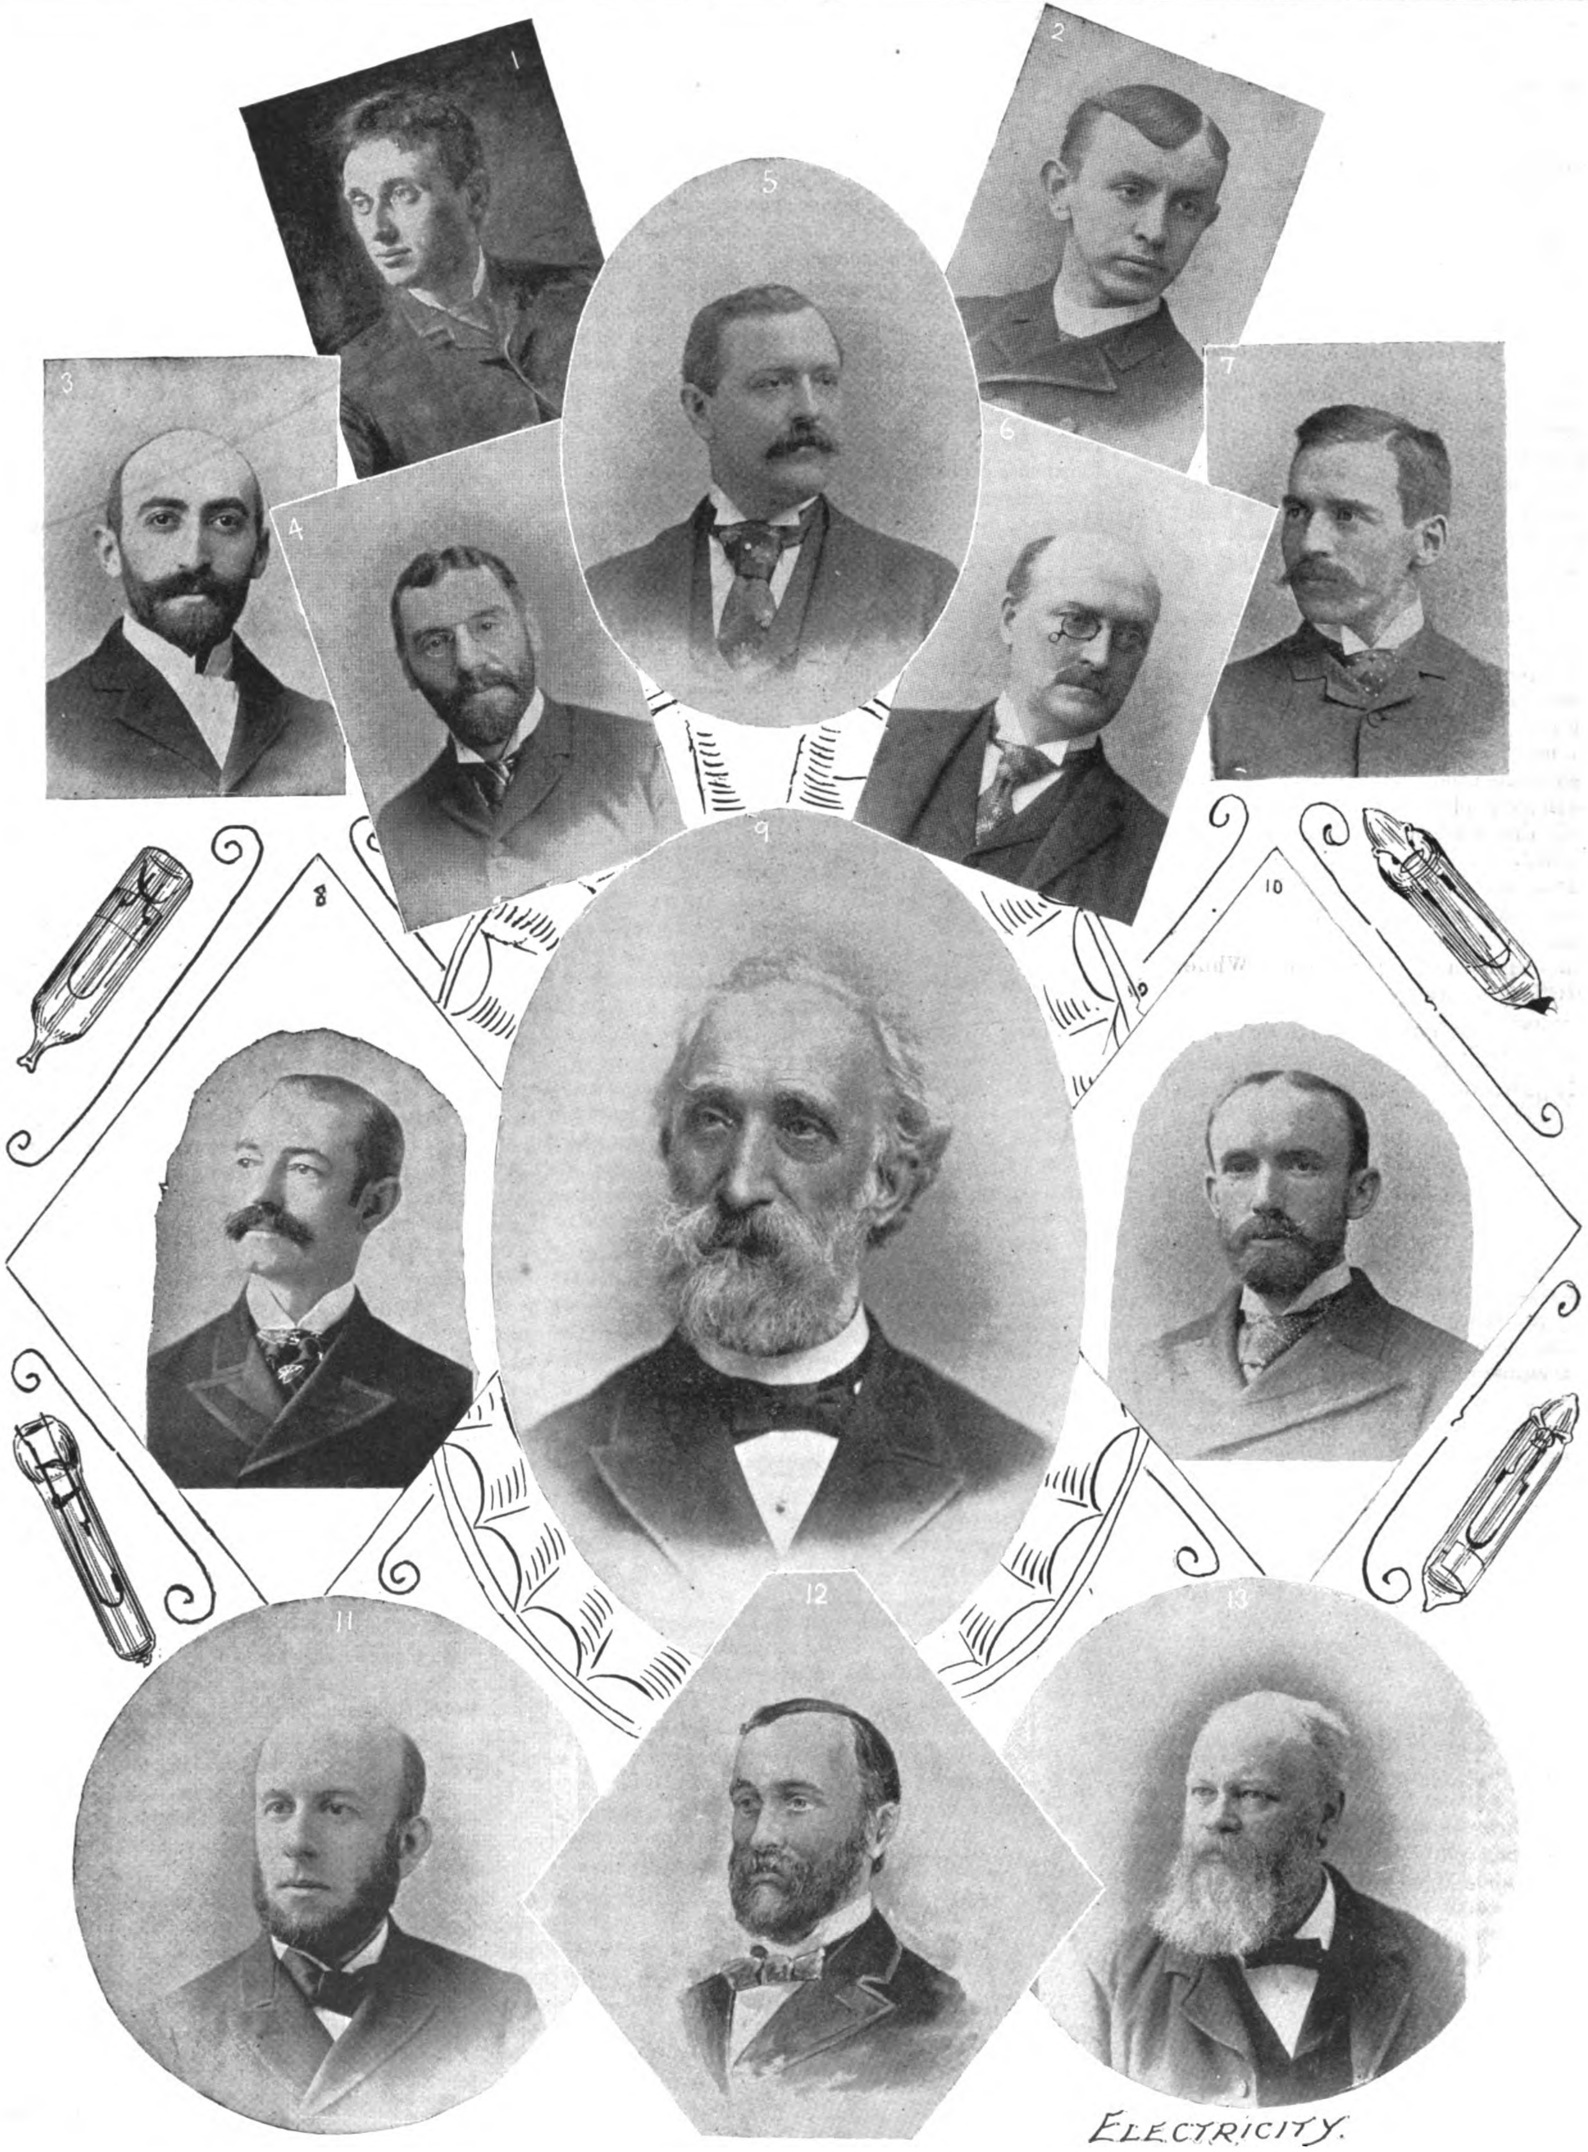
He was called to occupy the same position in 1864 with the Russo-American Telegraph Company, and while in this service made some explorations of the territory between British Columbia and Alaska. Subsequently he settled in New York City as an electrical engineer, where he has since resided.

With Edison, in 1870, he invented the one-wire printing telegraph or "ticker," and in 1872 he invented the rail circuit for automatically controlling block signals, a patent largely in use on the principal American railroads at present. Besides these he secured a number of other patents on railway and telegraph apparatus.

In 1885 he was elected president of the American Institute of Electrical Engineers and for several years was editor of the *Electrical Engineer*. He is also the author of "The Electric Telegraph," and "Life and Work of Joseph Henry."

The defeat of Edison's claims to the invention of the incandescent lamp is in the nature of a personal victory for Mr. Pope, he having from the first consistently maintained that Edison's incandescent lamp work was not wholly original.

Mr. Pope was thoroughly convinced, after a brief study of the Goebel matter, that Goebel's work was at least equal to the early work of Edison in the same direction, besides having been done nearly thirty years earlier.



A HISTORIC GROUP.—THE MEN WHO ESTABLISHED THE CLAIMS OF HENRY GOEBEL.

1. Louis D. Brandeis. 2. Edward E. Cary. 3. Henry S. Kaliske. 4. Jacob Heilbron. 5. J. H. Rhotehamel. 6. Judge E. B. Adams. 7. A. S. Fowler. 8. W. C. Witter. 9. Henry Goebel. 10. W. H. Kenyon. 11. Charles R. Cross. 12. Judge Moses Hallett. 13. Franklin L. Pope.

CHARLES R. CROSS.

Charles Robert Cross, Thayer Professor of Physics, Massachusetts Institute of Technology, was born at Troy, N. Y., March 29, 1848, his parents being of good old New England stock. He graduated at the Institute of Technology in 1870, and was thereupon appointed Instructor in Physics and assumed charge of the Department of Physics in 1877. It was entirely at the suggestion of Professor Cross that the course in Electrical Engineering was established at the Institute. This department since its establishment in 1882 has always been under Professor Cross's charge, and some of the best known electrical engineers in the country owe their success to their training under him. It is interesting to make note of the fact that this was the first course of the kind in the country, and one of the first in the world. It is now among the most comprehensive, having one of the very best equipped laboratories and largest number of students. Up to June, 1892, 131 students had been graduated in this course.

Professor Cross has contributed many interesting and valuable papers on electrical and acoustic topics to various scientific journals and magazines, more particularly to the American Academy of Arts and Sciences. For many years he has been the electrical expert for the Bell Telephone Company, having given testimony and carried out elaborate experiments in connection with the different lawsuits the Bell Company has had.

Professor Cross has a singularly lucid manner of speech, and is a scientist who can make the most learned dissertations intelligible and instructive even to a layman or a United States Circuit Court Judge.

JUDGE MOSES HALLETT.

Judge Hallett is one of the most prominent and able jurists of Colorado, now holding the position of District Judge of the United States for the District of Colorado to the entire satisfaction of his State and county, whose able and careful decisions upon grave and important matters have become the valued property of the State and are considered as authority wherever they are known.

He was born July 16, 1834, in Jo Daviess County, Ill. Receiving an academic education, he began the study of law in the fall of 1854, in the office of E. S. Williams, of Chicago, and in the fall of 1857 was admitted to the bar and immediately began the practice of his profession in that city. In the spring of 1860, charmed by the gilded accounts of Pike's Peak, he went to Colorado, and for a short time engaged in mining. It did not take long to convince him that he was better adapted to the practice of his profession than to the unearthing of mineral wealth, and in accordance with this conviction he located in Denver and resumed the practice of law, continuing until April, 1866, when he had acquired sufficient prominence in his profession to warrant his appointment as Chief Justice of the Territory of Colorado. He continued in this responsible position for about ten years, being twice reappointed.

At the expiration of this time, the Territory having taken its place as a State in the American Union, Judge Hallett was called upon to accept the more responsible position of District Judge of the United States for the District of Colorado, which office he has since held. He has lately been assigned to the United States Court of Appeals as one of the judges, for a term of one year. His judicial record is universally respected. Besides his judicial honors, he has served two sessions in the Council of the Territorial Assembly, where he rendered efficient service. In short, he has aided very largely, not only in settling many of the disputes that have come up in the Territory and State, but he has also done a great deal toward establishing justice and dignity in the Colorado courts.

HENRY GOEBEL.*

Heinrich Goebel was born in the little village of Springer, a few miles from Hanover, Germany, on the 20th of April, 1818. His father, Friedrich Göbel, was a manufacturer of chocolate, and a man of some prominence in the community in which he lived. He was for a time, about 1819-20, consul for the Netherlands in New York. Heinrich received a tolerably good education in the Lutheran Church school of his native village. He was not content to pursue his father's business, but preferred that of a watchmaker and optician.

Having in the course of his business frequent occasion to repair philosophical apparatus for the instructors in the Technological School of Hanover, he soon became much interested in physical research, in which he was aided and encouraged by one Professor Mönighausen. In 1846 the technical journals of Europe published accounts of the now well-known electric lamp invented by J. W. Starr, of Cincinnati. As Goebel was well skilled in the construction of barometers and thermometers, Professor Mönighausen often discussed with him the possibility of making an electric lamp on this principle, and they even went so far as to make some experiments in this direction, but without successful results.

In 1848, being then thirty years of age, Goebel determined to seek his fortune in the United States. Within three or four years after his arrival in this country he had constructed a zinc-carbon battery of about 80 large cells, by the aid of which he astonished the neighborhood one dark night by exhibiting from the roof of his house an electric arc formed between two pieces of carbon.

He had noticed, in trying to burn a piece of wood cut from the ferrule of a broken walking-stick that some portions of the wood from which the air was excluded by the ferrule were carbonized, and upon testing a piece of this carbonized wood he found it to be a conductor of electricity. This suggested to him the employment of wood fibre, carbonized in a similar manner, for the light-giving conductor of the lamp. Among various woody materials tried were splinters from a bamboo pipestem, which were found to answer admirably. As early as 1855 Goebel had succeeded in making quite a number of lamps, which, by the use of about 30 cells of zinc-carbon battery, emitted, for a short sime, a brilliant and beautiful light.

He made many forms of lamps from time to time, some of which were almost constantly in use in his jewelry shop in this city from 1855 to 1880.

In 1881 Mr. Goebel entered the employ of the American Electric Light Company, where he first learned of a dynamo electric machine.

Although seventy-four years of age, Mr. Goebel's figure is as erect, his eye as bright, and his hand as steady as a man's in the prime of life. Few can excel him, even at his age, in delicacy, skill and accuracy of touch in the finer processes of handicraft. Of an unassuming, cheerful and kindly nature, nothing delights him more than to converse upon topics relating to his favorite pursuits of optics and electricity, or to relate with a humorous twinkle of the eye some of the scientific practical jokes that in younger days he was wont to play upon his unscientific and unsuspecting associates. After a long, industrious and well-spent life, he is passing his declining years in comfort and contentment in a quiet home in this city, enjoying the respect and regard of his family and friends.

THE GOEBEL DEFENSE.

On Monday, January 16, 1893, the Edison Electric Light Company et al. moved for an injunction against the Beacon Vacuum Pump and Electrical Company before Judge Colt in the United States Circuit Court at Boston. Acting on the assertion of defendants' counsel that they had new evidence to introduce, Judge Colt granted an extension of one week.

Accordingly, on January 23, the case was formally opened, and then was presented, for the first time, what has passed into history as the "Goebel Defense."

Plaintiffs were represented by Frederick P. Fish, Dyer & Seeley and Clarence A. Seward and defendants by Witter & Kenyon of New York and Louis E. Brandeis of Boston.

The electrical experts were Franklin L. Pope, Charles R. Cross and Edward E. Cary.

The affidavits introduced by defendants showed that at least twenty-five years before Edison began experimental work on the incandescent lamp Henry Goebel had made scores of successful lamps on practically the same lines as the lamp for which Mr. Edison finally received a patent. Several of these early Goebel lamps were offered in evidence. While Goebel was not entirely unknown, the full extent and the importance of his work had not been appreciated by the few who knew of it, and it had remained for Messrs. Witter & Kenyon to gather the facts and make a presentable case. The electrical world was startled when the full report of the trial was sent out in an extra issue of ELECTRICITY and the results of the establishment of Goebel's claims were properly understood. Several lamp factories had already been enjoined for infringement of the Edison patent, and it had been believed that nothing could break the monopoly of the General Electric Company before the expiration of its patent.

The sympathies of the entire trade were with the Beacon Company at the start, and when the case was concluded the opinion was prevalent that the injunction would not be granted. Defendants' case, however, had been of necessity prepared in a hurry, and there were, in the opinion of Judge Colt, fatal omissions in the chain of evidence. The injunction was granted on February 18.

The Columbia Incandescent Lamp Company of St. Louis was among the previously enjoined companies. Immediately upon the conclusion of the Beacon case, President Rhotehamel of the former company engaged Witter & Kenyon of New York and Adams & Fowler of St. Louis as counsel, and immediately went to work to complete the evidence in the Goebel Defense, and to establish the identity of the various lamps exhibited.

The final hearing in the suit for a preliminary injunction in the case against the Columbia Company came up before Judge Hallett at St. Louis on the 11th of April and was concluded on the 14th. Plaintiff was represented by Frederick P. Fish, Clarence A. Seward and P. Dyer of New York and Henry Hitchcock of St. Louis.

The Goebel Defense was thoroughly established, and Judge Hallett refused to grant the injunction prayed for.

The Columbia Company, however, was placed under bonds pending the final trial of the case and the examination of witnesses.

The bond was filed within twenty-four hours, and the Columbia Company at once resumed the manufacture of incandescent lamps.

NOTE.—Copies of "A Historic Group," printed on heavy paper, with wide margin, for framing, can be supplied by ELECTRICITY, at fifty cents each.

---

* From a sketch by Franklin L. Pope in the *Electrical Engineer*.

The Action of Continuous and Alternating Currents on Fuse Metals.*

BY C. P. MATTHEWS.†

For the protection of electric circuits from the passage and consequent heating effects of currents of abnormal intensities, no device is in more general use than the so-called safety-fuse. Commercially the fuse appears in a variety of connecting devices and inclosing boxes, classed as thermal "cut-outs," and familiar to all having to deal with the distribution of electric energy. The protective element in all such consists of a wire or strip of some easily fusible metal of such current carrying capacity that it will melt under the heat developed by an excessive current. In points of simplicity, cheapness, ease of adjustment and low resistance, the safety-fuse possesses advantages over most, if not all, electro-magnetic safety devices. Experience shows, however, that unless certain conditions for successful working are carefully observed, the safety-fuse may fall far short of furnishing satisfactory and reliable protection.

With a view of studying these conditions, and of obtaining at the same time reliable data on the fusion of conductors under circumstances closely approximating those of actual practice, a series of experiments, some of the results of which appear in this paper, were recently made in the physical laboratories at Cornell University.

This experimental work, which was undertaken by several persons, may with propriety be divided as follows:

Part I. On the behavior of various alloys under the action of direct currents, with special reference to their use in thermal cut-outs.

Part II. On the *disintegrating* effect of the alternate current on fuse metals.

PART I.

The first experimental work of any extent on the electric fusion of wires was performed by W. H. Preece, F. R. S., in 1884.[1] He showed that the relation between diameter and fusing current is parabolic,[2] being

$$C = a\,d^{\frac{3}{2}},$$

where a is a constant for any given metal or alloy. This relation is obtained as follows: The rate at which heat is developed by a current C flowing in a wire of resistance R is

$$H = \frac{C^2 R}{J}$$

in thermal measure. The resistance of the wire may be expressed in terms of its dimensions and the specific resistance ρ of the material thus:

$$R = \rho\,\frac{l}{\frac{1}{4}\pi d^2},$$

By substitution,

$$H = C^2\,\frac{4\rho l}{J\pi d^2} = K\,l\left(\frac{C}{d}\right)^2. \tag{1}$$

Now, as the temperature rises, there are heat losses by radiation and by convection into the surrounding medium, and also, to a greater or less extent, by conduction into the terminals. Neglecting this last, and assuming the radiation and convection to be proportional to surface (to what extent this is justifiable will be presently considered), we may write for the rate at which heat is thrown off

$$H' = \pi\,d\,l\,\varepsilon(T - T^1), \tag{2}$$

where $T - T^1$ is the excess of temperature of the wire above that of the envelope, and ε is the emissivity of the surface, or the number of water-gram-degrees emitted per second, per square centimetre of surface, per degree rise of temperature. Equation (2) may be written

$$H = K'\,d\,l$$

for any permanent temperature. With a constant current a condition of affairs is soon reached when heat is lost at the same rate as that at which it is generated by the current, and a constant temperature obtains. We then have

$$H = H', \text{ or}$$

$$K\,l\left(\frac{C}{d}\right)^2 = K'\,l\,d,$$

from which

$$C = a\,d^{\frac{3}{2}},$$

where

$$a = \sqrt{\frac{K}{K'}} = \sqrt{\frac{\pi^2 J\varepsilon T}{4\rho}}.$$

This result shows the fusing current to be independent of the length of the conductor. Evidently a is the current necessary to fuse a wire of unit diameter. The emissivity is here assumed to be a constant quantity for a given surface. The valuable experiences of Kennelly[1] on the "Heating of Conductors by Electric Currents," in which the radiation and connection losses were separated, and the results of Ayrton and Kilgour,[2] indicate that such is not strictly the case. These latter investigators found that for any temperature the emissivity is the higher the finer the wire. The rapidity with which fine wires heat and cool is a matter of common observation. Mr. Kennelly's results indicate that the convection is proportional to the temperature elevation for small differences of temperature, and that moreover losses occurring in this way increase slightly with the diameter, and are dependent on the form of the conductor. For the purposes of calculation of the fusing currents of wires, however, it is sufficient—as both the results of these investigations and those of Mr. Preece show—to consider only the total heat loss, and to assume the emissivity a quantity independent of the diameter and temperature elevation.

Mr. Preece's first experiments with platinum wires of small diameter do not appear to confirm the foregoing relation. He says: "Platinum wires—especially those of small diameter—are liable to flaws which practically reduce their effective diameter to a great extent; and also the larger wires from their greater weight necessarily tend to part asunder at a lower temperature than those which are lighter, and in which the strain is less."

In 1887[3] Mr. Preece presented the results of an elaborate series of experiments on wires of different metals, showing that the theoretical relation is quite strictly borne out in experiment except for wires of extremely small diameters. The following year "final and corrected" values of a were announced for the following metals:

Copper	10244
Aluminium	7585
Platinum	5172
German Silver	5230
Platinoid	4750
Iron	3148
Tin	1642
Alloy (Tin 1, Lead 2)	1318
Lead	1379

In determining these constants, Preece used six inch lengths of wire, while to ascertain the value of the same metals as cut-outs 1¼ inch lengths were used. It will be noticed that a value of a is given for only one alloy of lead and tin. In the course of experiments of which this paper treats, a redetermination was made for lead and for tin, and at the same time values of the constants were determined for various alloys of these metals. These latter are, it is believed, now announced for the first time. These metals were dealt with especially, because of their extended use in the manufacture of fuse-wires.

To determine to what extent the fusing current is influenced by the cooling effect of the terminals, pieces of wire of given diameter and composition but of varying lengths were successively tested. The marked variation in current is shown graphically in Fig. 1, Curve A. It will be noted that while an 8 inch piece fused at 6.6 amperes, a ½ inch piece of the same wire carried 12.5 amperes, or an excess of nearly 100 per cent., before yielding. For lengths of this wire greater than 6 inches, the conduction losses are practically nil in their influence on the value of the fusing current. The reader is referred to a formula deduced by Lord Kelvin[1] for the loss of heat occurring in this way. The practical point to be observed at this juncture would seem to be this: manufacturers cannot accurately rate their fuse-wire unless the length of the specimen to be used is specified. In the fuse-blocks in common use it is impracticable to use extreme lengths, yet if 3 inch pieces were used, the cooling effect would not be serious. Fuse-blocks are on the market employing from ½ inch to 3 inch lengths of wire, and all the variation indicated by the curve may be expected.

In the experiments to determine a for alloys of lead and tin, ordinary commercial metals were used, for, although the fusing current is affected by the presence of impurities, yet it was considered better to experiment with such grades of metal as would be used in practice. The alloys were cast in the form of cylindrical slugs, and these were drawn into wires varying in diameter from 10 to 100 mils. These were tested with great care. A Thomson graded ammeter was used to measure the current, the instrument being frequently calibrated during the work. For varying the current strength, a liquid resistance was used. The box containing the electrolyte was provided with a sliding contact, such that the current could be increased or decreased continuously without break or undue fluctuation.

There is an important *time element* to be considered in connection with the phenomena of fusion. A certain interval elapses before the wire reaches the permanent temperature corresponding to a definite current. The duration of the current in this portion of the work was 60 seconds, experience showing that if a wire of moderate diameter did not fuse in that time under the action of a certain current it would not fuse at all. Curves A′ and B′ of Fig. 5 illustrate the magnitude of this effect in a particular case, the time intervals being as 1:2. The variation in fusing current exceeds 5 amperes for the larger sizes. It should be noted in this connection that unless massive terminals are used they may themselves become heated, thereby checking the flow of heat through the ends of the wire, and tending to promote ultimate fusion.

The limits of this paper do not allow the insertion of the complete data on these alloys. The curves of Fig. 1 (B and C), however, may be taken as representative, and indicate that the "three-halves power law" was quite closely followed, a result which was obtained in all the other cases. From each observation of the current and diameter a value of the quantity a was computed; the mean of these values was taken, and a curve of calculated fusing currents drawn for each alloy. These curves appear in Fig. 2. It will be noted that while the temperature of fusion of tin is considerably lower than that of lead, its *fusing current* is about 24 per cent. higher. This is undoubtedly due to the difference in the resistance of the two metals. The

(Concluded on Page 262.)

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - -	$2.00
FOREIGN COUNTRIES, - - - - -	$4.50

ADVERTISING RATES:
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

The Trust in Cleveland.

There seems to be a slight misunderstanding in Cleveland in regard to the exact status of the Cleveland General Electric Company.

ELECTRICITY knows little of the gentlemen who pose locally as the controlling element in this company, and we are willing to assume that they are patriotic citizens, with the best interests of their city at heart.

We do know, however, that whatever else these gentlemen may be, they are only dummies as regards the conduct of the Cleveland General Electric Company. This company is controlled absolutely by the Electric Trust, whose chief offices are at 44 Broad street, this city.

It will be well for the city officials and the taxpayers of Cleveland if they inform themselves as to the exact condition of affairs before any further concessions are granted.

A little study of history would not be out of place, and the original stockholders of the Brush Company can furnish the points.

The citizens of Cleveland ought to be informed by the daily press of that city that the Boston speculators who wrecked the Brush Company have now attempted to control absolutely the public electric lighting of the town, and to render any competition impossible.

When we speak of the Brush Company as having been wrecked, we do so advisedly. From the day when a controlling interest in this company was purchased by the Thomson-Houston people it has been used simply as a convenience and nothing else. It has been a respectable dummy bidder for certain contracts which it was never intended it should get, and it has been allowed to sell some plants in towns where the Thomson-Houston people had given exclusive licenses, and where, to do any further business, some other name had to be used. But where there has been a really profitable contract, the Brush Company has been sidetracked every time. Thus the magnificent property has been reduced from a proud and leading position in the electrical field to one of no consequence whatever—the plant incurring an actual loss now of about $30,000 per year, and being in imminent danger of being closed down for good. It is only justice to state that the local management of the Brush Company is not responsible for this condition of affairs, and that Mr. Hamill and his associates are powerless in the hands of the Thomson-Houston wreckers.

An attempt is now being made by these Boston squeezers, who are in full control of the Electric Trust, to place the city of Cleveland at their mercy; to secure such privileges as will render their new position impregnable, and then to demand what price they see fit for any kind of service they choose to give.

Cleveland is not the only town where this scheme has been tried. Philadelphia is now wrestling with the problem through a legislative inquiry into Trust methods, and Detroit has already concluded that the only redress is to be found in a municipal plant.

We predict that sooner or later Cleveland will have to face the matter squarely, and either install a municipal plant for the street lighting or be robbed to the tune of thousands of dollars a year.

Cities and towns throughout the United States should give their attention to the matter of public lighting before any further contracts are made or concessions granted. Wherever the Electric Trust or its sub-companies are in the field, robbery may be expected.

The manufacturing plants, real estate, etc., of this Trust do not aggregate over $12,000,000 in value. On this foundation a $50,000,000 combination has been formed. Interest must be paid or the whole scheme collapses.

And the only possible way of getting the interest is to squeeze it out of the taxpayers of the various municipalities through straw companies, which the Trust controls by the dozen, like the Cleveland General Electric Company.

The Cleveland *Press* has already taken this matter up, and it behooves the *Leader* and the *Plaindealer* and all the rest, regardless of politics, to stand up for the best interests of the city.

* * *

A Pleasant Incident.

The visit to the new factory of the Crocker-Wheeler Company at Ampere, N. J., proved of the greatest interest to the large party which assembled there, owing to the entire novelty of the new plant, and it may be said without doubt that the operation of the direct-driven machine tools exhibited there produced a most favorable impression upon all who visited the works. Aside from the question of economy, the simplicity of the general arrangements and the facilities which these machines afford for procuring power at any point independent of belts and shafting constitute advantages which are entirely lacking in other shops. In other words, each machine is an independent unit and can be operated in any location by simply connecting it by wires to a system of overhead conductors which are run from the main generators through all the shops.

It would appear that considerable economy of power should result from this system also, not only in the first cost of the plant but in the operating expenses as well, although of course no actual figures are available for a comparison of the two methods. It is well known, however, that in a factory, especially where the shafting is distributed over a wide area, a considerable amount of power is required to run this even when the connected machinery and countershafts are running idle. And it may also be noticed that only when a heavy machine is thrown on does it become apparent at the engine. In the present case this constant load is entirely eliminated, and with even but a moderate efficiency at the motors it seems as though considerable saving in power must be accomplished.

* * *

THE claims of the Trust to fundamental trolley patents are so flimsy that we predict they will never push the case to trial. The action was unquestionably brought solely with a view to its immediate effect on the stock market.

It may be prudent, however, to investigate the methods by which such alleged "patents" are issued. Patents covering the same device were applied for seven years earlier and have not yet been issued.

* * *

Industrials or Frauds? Mr. Russell Sage is quoted as follows by the New York *World* in regard to the causes of the present crisis in the financial world:

> "Industrial stocks are at the bottom of all this trouble; industrial stocks are good for nothing. I wouldn't have any of them. . . . Industrial corporations are illegitimate. . . . As for the Trusts, they are the worst things this country ever developed. Every one is illegitimate and pernicious to the real interests of the country. What do you think of a Trust that guarantees commercial paper? They had one like that out West. It broke up—yes, of course it did. But don't you worry about Trusts. They have got to go in the end. They will be abolished. Public sentiment will destroy them if the law does not."

Mr. Sage's remarks are perhaps too sweeping, as there are stocks of many manufacturing companies for sale in Wall Street which are sound in every particular, and really gilt-edged investments.

He doubtless had in mind Whiskey, Cordage and General Electric—three Trusts which present several features of marked similarity.

First of all, of course, comes the immense over-capitalization; next the problematical value of the assets. But what is the weakest spot of all is the fact that the executive heads of these Trusts have given their entire attention to stock gambling and manipulation, and not to the large manufacturing interests represented.

No Trust on the Street, with the possible exception of Whiskey, stands on so flimsy a footing as General Electric—none so nearly approaches a barefaced swindle; and this because it has the support of banking houses of reputation like Drexel, Morgan & Co. and Lee, Higginson & Co. The very fact that these concerns have assisted in forcing watered stock of the company above par, and then unloaded on the humbugged public, makes the fraud the more reprehensible and disgraceful.

Of course electrical men are not deceived at all by the emphatic statements put forth by these bankers. It is well known in the trade that Drexel, Morgan & Company and Lee, Higginson & Company were both involved for millions in the Edison and T.-H. Companies. They are making a desperate but disgraceful effort to get their money out, with as little regard to the actual value of the stock they are selling as the green-goods man has for the value of the package of bricks shipped to his victim.

The fact is that the only object in the forming of Trusts like Cordage, Whiskey and General Electric was a wholesale fraud on the public, an attempt to sell something for five or ten times its value.

It is a wholesome sign of the times that the days of Trusts are about over. One more year will wind them all up. Meantime thousands of small investors have been humbugged and swindled out of their few hundreds of savings in order that Trust magnates like Waterbury and Greenhut and Coffin may grow rich.

Our Group of Portraits. On another page of this issue will be found a group of portraits of the leading men connected with the recent litigation which resulted in establishing the validity of Goebel's claims to priority of invention of the incandescent lamp.

The electrical trade generally certainly owes a debt of thanks to these gentlemen for carrying to a successful conclusion a case which in many ways appeared almost hopeless and which offered at first little encouragement for further opposition to the Edison claim with the prestige gained from a series of successful suits.

Their victory for these reasons is the more worthy of congratulations from the electrical fraternity, coming as it did at a time when defeat meant at least a temporary destruction of this line of business and its relegation to the hands of an extortionate monopoly.

* * *

The Institute Meeting. At the general meeting of the American Institute of Electrical Engineers held on Wednesday last some discussion was heard on the provisional programme for the World's Electrical Congress to be held this summer at Chicago. The programme, which was printed in the January and February numbers of the Institute Transactions, relates largely to the nomenclature of standard electrical units, about which some confusion exists at present. Even in a case so apparently simple as the naming of the poles of a magnet it is ambiguous, as the north pole of a magnet is commonly known as the pole which is attracted to the north pole of the earth, although we know that these poles must be of opposite polarity for the reason that they are mutually attracted. The standard of illumination is another unit which has no well defined value. The discussion, which related to mooted points of this character, will be published in the electrical journals previous to the meeting of the Congress, according to a resolution which was passed, in order to familiarize the absent members of the Institute with the subject under discussion, and draw out a full expression of opinion upon the suggestions to be made.

* * *

IT IS just about ten years since the Thomson-Houston people started in on what has become a conspicuous career. Mr. Coffin was from the start the controlling head. He surrounded himself with subservient dummies and inaugurated an entirely new practice in the management of a large manufacturing enterprise.

From the first his interest centered in stock manipulation. Up to a little over a year ago, while his operations were confined to Boston and vicinity, his success was marked. His company paid large dividends—on paper—and he secured to a remarkable extent the confidence of the New England investing public. When the General Electric Trust scheme was launched he found ready backers.

Then the field of his operations was enlarged, and he came to Wall Street. His path here has not been strewn with roses, and for the best of reasons. Wall Street had already made the acquaintance of several Napoleons of Finance, like Ward and Ives, and was not too favorably impressed with Napoleon Coffin.

Paper dividends and paper values don't go in this locality. And when Mr. Coffin, with the aid of two of the most unscrupulous manipulators in the Street, White and Keene, began his campaign, the rank and file of Wall Street smiled—and waited.

They did not have many months to wait, when an opportunity came to place General Electric stock at somewhere near its actual value.

Mr. Coffin is now aware that a big man in Boston is not necessarily a big man in New York. He will be remarkably fortunate if he carries away from Wall Street all that he brought there, to say nothing of adding to his pile.

* * *

Electricity in Medicine. The interesting paper on the above subject by Dr. W. J. Morton, which we give as fully as space permits in this issue, explains very clearly the difficulties with which the physician is confronted in the use of electricity as a therapeutic agent, and it is to be noted that the lecturer avows frankly that its introduction in medicine was premature and its application was too often a matter of experiment in the hands of those whose knowledge of this science was but vague. There can be no doubt of its efficiency in many cases, but unfortunately for the science the use of electricity has become so thoroughly associated with the advertisements of medical quacks that the public have come to look upon it with suspicion, and often this opinion is well founded.

There are, however, legitimate and well proved uses for electricity in medicine, and they are practised by the most conservative physicians, while on the other hand the men who have enthusiastically considered it a universal panacea have been the ones to throw the greatest obstacles in the way of its progress.

One point of Dr. Morton's lecture is to be especially remarked, viz., the general application of the electric current in distinction to the local applications which have been generally used. The operation of submitting a patient to a bath of atmospheric electricity, so to speak, which recent inventions have made possible, appears to offer a field worthy of careful study.

* * *

WE ARE gratified to know that the Hon. Tom Marshall, of Pittsburg, will appear for one of the defendants in the Pittsburg larceny case. He may not prove the innocence of his client, but he is certain to furnish entertainment and an intellectual treat to those who hear his argument. We will endeavor to print the latter in full.

* * *

IT CANNOT be said that the whiskey business has been disgraced by the Whiskey Trust. It can be said, however, that the electrical industry has been disgraced by the Electric Trust.

* * *

AS WE go to press news is received that a receiver has been appointed for the National Electric Manufacturing Company of Eau Claire, Wis.

(*Continued from Page 259.*)

specific resistance of tin is 13,360; that of lead 19,487 (C. G. S). There is possibly also some difference in the emissivities of the two surfaces. Curve C, Fig. 1, illustrates the effect of enclosing the fusible wire in glass tubes. As would be expected the convection is thereby checked, and the fusing current very appreciably lowered. This is a point which should not be overlooked in practice, that is to say, the nature of the fuse-block, whether closed or open, should be considered. The constants obtained were :

Alloys	Per Cent. Lead.	a	Preece's Constant.
Tin...............	0	1592	1642
Tin 2, lead 1......	33.3	1441	
Tin 1, lead 1.....	50	1328	
Tin 1, lead 2......	66.6	1156	1318
Tin 1, lead 4......	80	1131	
Lead.............	100	1283	1379

Platting these constants as ordinates, with per cent. of lead as abscissæ the curve shown in Fig. 3 was obtained. From this curve the constant for any alloy of lead and tin whatsoever may be taken, and the current necessary to fuse a wire of any diameter readily calculated.

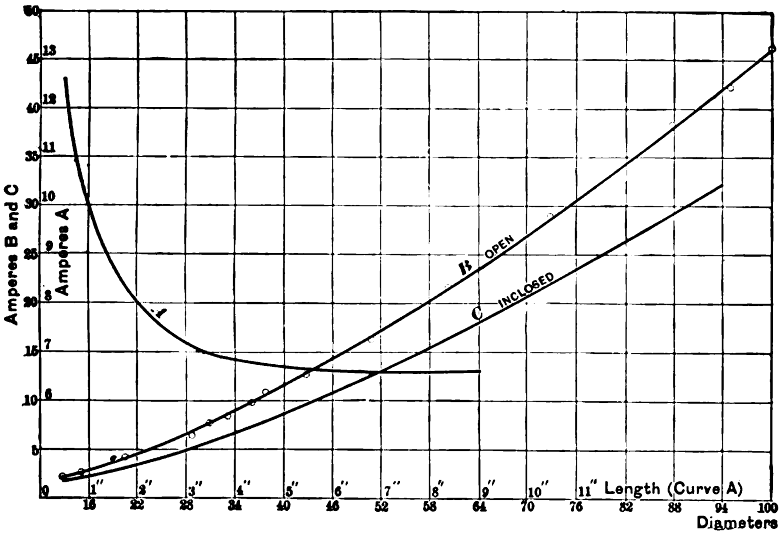

FIG. 1.

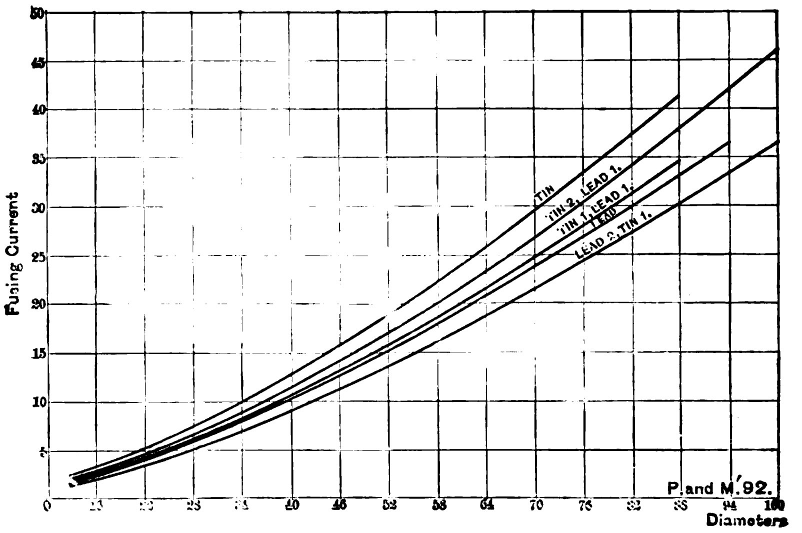

FIG. 2.

5	.0305	9.65	23.4	32.16
7	.0351	12.76	27.5	35.37
10	.0395	15.78		

Attention is called to the fact that those values of a which may be considered as redeterminations are all lower than the values announced by Mr. Preece in 1888.

Comment on this fact is made in the original report in the following words : "Had they been higher, we should have ascribed the difference to the fact of our using wires of shorter lengths. As it is, we can only say that Mr. Preece doubtless experimented with chemically pure metals, while our wire was drawn from the commercial article. He gradually increased the current until fusion occurred ; we endeavored to find *what current, when it had plenty of time to bring about a permanent state, would fuse the wire.* In increasing the current continuously from zero to that which melts the wire, there is danger of getting too high current readings. Mr. Preece's first determinations were entirely too high, as his later investigations show."

TABLE B.

5	:0374	12.6	10.81
10	.0533	21.24	18.29
20	.0804	42.61	36.18

In order to ascertain the status of marketable fuse wire, a number of samples were obtained from different manufacturers and tested under conditions similar to those already described. The results were represented graphically by curves, only two sets of which are here reproduced. In Fig. 4 curve A is that obtained where 2 inch specimens were tested, and, as will be seen, is not far from a ⅔ power curve. When, however, ½ inch pieces of the same wire were tested, curve B, much higher and distorted, was obtained. The marked cooling effect of the terminals is here apparent. Curve C is the most remarkable of all. One-half inch lengths of the same sizes of wire were successively fused in a porcelain ceiling cut-out block. This block was so constructed that the wire came in contact throughout its length with the cooling surface of the porcelain. The heat was conducted away so rapidly that the current reached the abnormal values shown before rupture occurred. For example, a 7-ampere fuse did not "blow" until more than 35 amperes were flowing in the circuit. Curves A', B' and C' in Fig. 5 represent the behavior of the best sample of wire tested. This wire was quite uniform in diameter, and gave evidence of careful rating. The curve of rating should be of the same general equation as that of fusion, since both represent isothermal conditions.

The requirements for an efficient safety fuse may be summed up as follows :

1. Promptness of action.
2. Low fusing point.
3. Permanency under normal conditions.
4. Moderately low resistance.
5. Firm and lasting contact.

Promptness of action requires that the temperature of fusion should not be too far removed from that attained when the wire is being worked at its rated capacity. Moreover, it is important that the metal should not undergo chemical changes produced by the action of the heat which may appreciably alter its melting point. The formation of oxides may or may not promote prompt fusion. In the case of pure tin and some of its alloys, a coating of oxide is often formed which retains the molten metal some time after the temperature of fusion has been passed, ultimate rupture usually occurring with considerable violence. On the contrary, the rapid oxidation of iron and copper wires seems to favor prompt fusion.

The question of low fusing point is one with which the fire underwriters are concerned, since wires fusing at high temperatures introduce an element of danger from fire. With fuses enclosed in properly constructed blocks, the danger from this source is not great, and the necessity of employing a metal of low melting point is not so important as might be imagined. Experience shows that fuses made of nearly all the metals available for such purpose, will melt without dangerous scattering of particles or liberation of hot gases, when the current is gradually increased until the break occurs. This, however, is a condition which rarely obtains in practice. Mr. Preece experimented with various metals to determine their behavior on short-circuit. He made for each metal a verbal description of the character of its fusion, such as : "Scintillating particles flew in all directions to a great distance." His results are unique and comprehensive as regards the variety of metals experimented with, but suffer from the inadequacy of the English language to express with proper shading the nature and degree of the disturbance in each case. The author of this memoir hit upon the plan of surrounding the fuse with a paper cylinder about 3½ inches in diameter and 10 inches in length, and then exploding the fuse by an excess of current. In this way a series of autographic records were obtained, showing with considerable accuracy what happened in each case. These records are perhaps more curious than valuable, but they are undeniably interesting, and it is to be regretted that some of them can not be reproduced here. Owing to the cylindrical form of the paper, the particles of molten metal striking it, in any way but normally, traced out sinusoidal curves of continually decreasing amplitude. The vapors liberated colored the paper quite beautifully in many cases, and usually in characteristic tints, while an idea of the temperature attained was given by the degree to which the paper was burned. In most cases when ½ inch pieces were used an arc was established across the terminals, the intense heat of which was far more destructive than anything resulting from the temperature of the metal. The reader is referred to the original thesis[1] for these curious records, as well as for much other matter pertaining to a subject which, it is believed, is too liable to be regarded of trivial importance.

PART II.

What has been said in Part I will doubtless apply equally well to fuses on either direct or alternating current circuits, but in the latter case a new and annoying phenomenon, well worthy a special investigation, confronts the electrician. Reference is had to the subtle effect of the alternating current on fuse metals by reason of which they often yield when carrying currents well within their rated capacities. This phenomenon was mentioned in the editorial columns of the New York *Electrical Engineer* of September 16, 1891. Referring to a paper previously read before the Providence Convention of the Electric Light Association, the following words were used:

---

[1] In Cornell University Library. T 1893. 216.

"Perhaps the most important (point) was the nature of the fuses employed in the alternating current system, and the difficulties which accompany their use as described by several members. It would thus seem that the action of the alternating current has a disintegrating effect upon the fuses, which causes them to 'blow' after comparatively short use, and thus necessitating a constant renewal and supervision of the circuits."

The discussion following the paper above mentioned showed that this trouble had been experienced by many, and the hope was expressed that a careful investigation of the matter should be made. To cite a particular case: In the lighting system of the Cornell University Library eight 50 volt circuits were supplied with fresh fuses and a record kept of their behavior for a period of three months. During this time it was found necessary to furnish six of the circuits with new fuses, one circuit requiring three such renewals. In this last case the fuse was badly corroded, owing to water dripping from the floor above. The others were in dry and airy places, the contact being bright and firm. One of the fuses had the appearance of being simply cut, the opening being so narrow as to require close examination to detect it.

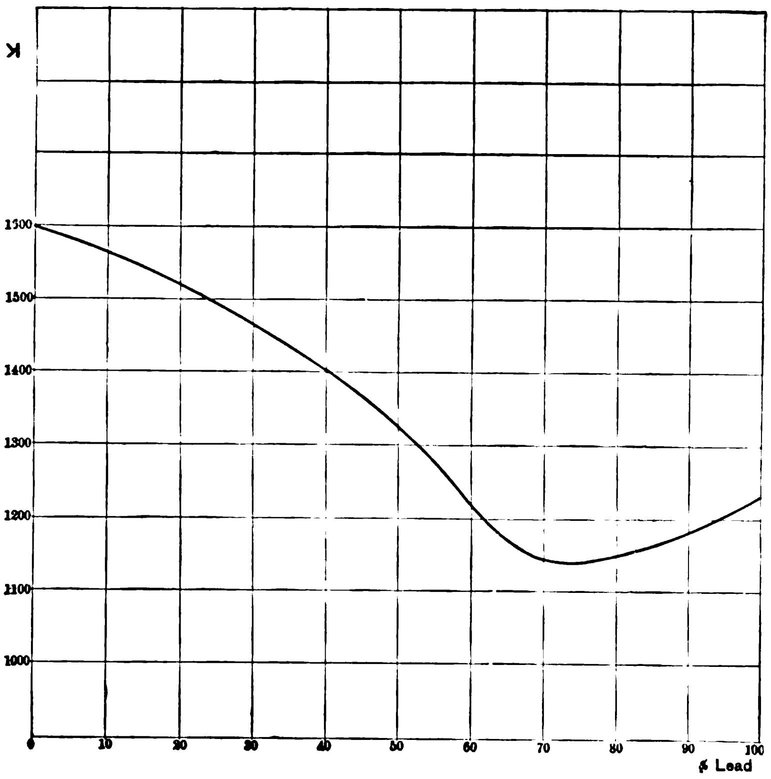

FIG. 3.

In their attempts to study this peculiar effect of the alternating current, the chief difficulty encountered by the experimenters was the fact that their reports had to be submitted in a comparatively short time. The subject is peculiarly one requiring long periods in which the action, whatever its nature, may proceed far enough to yield results of definite and quantitative value.

For the purpose of systematic investigation it was assumed that the effects of the current might be one or more of the following:

(*a*) A change in the resistance of the metal. It was thought that this would likely be a rise, with a result of lowering the value of the fusing current.

(*b*) A change in the physical properties of the metal. It was thought possible that a molecular change, such as crystallization, might take place, caused by alternate contraction and expansion from the heating effects of a varying current.

(*c*) Poor contact. This might be due to the loosening of the binding screws or other holding device, because of the frequent alternations. Imperfect contact due to electrolytic action would be more likely to occur with direct than with alternating currents.

(*d*) The effect of the current upon various metals and alloys was thought likely to be different, and consequently some alloys might be of just the right composition to overcome most of the difficulties mentioned.

The following results deal particularly with, and tend to corroborate, the first and second assumptions:

Samples of wire of various rated capacities were obtained from four different manufacturers (hereafter designated by i, ii, iii and iv), and of this wire fourteen pieces were chosen for use in the tests. The sizes and disposition of these several pieces were as tabulated.

No.	Make.	Rated Cap.	(Cms.) Len'th.	(Cms.) Diam'r.	(Squ're cms.) Area.	(Legal ohms) Resist.	(Microhms.) Specific Resist.
1	i	2	188	.0635	.00316	1.276	21.4
2	iv	2	105	.0476	.00178	.8727	14.76

There is some difficulty in accurately measuring the diameter of a wire of soft material. The foregoing values were obtained from a large number of measurements, the variation being never greater than 2 per cent., and this very seldom. Pieces of wire from each sample, varying in length from 2 to 10 feet, were wound into helices and mounted on wooden blocks. The ends were soldered to copper terminals of negligible resistance, the metal itself being used as a solder and resin as a flux. The joints were allowed to stand at least twenty-four hours before any measurements of resistance were taken. For the determinations of resistance, a "fall of potential" method was chosen as being best adapted to these small values. The standards used were a one ohm coil standardized at the Cavendish Laboratory in 1885, and a smaller compensated resistance composed of copper and carbon, accurately tested and compared with the standard coil.

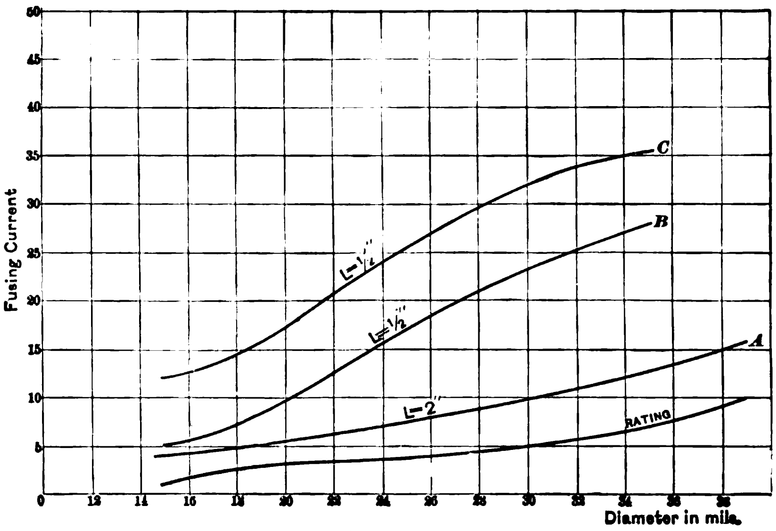

FIG. 4.

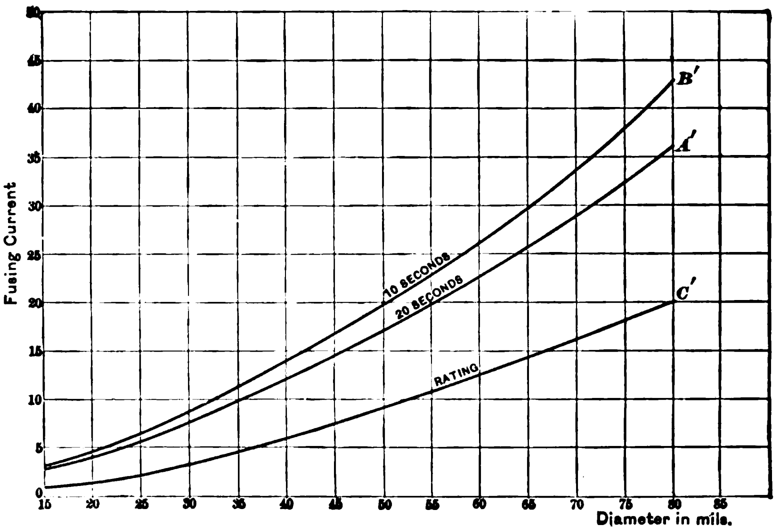

FIG. 5.

After the fuses were mounted as above described, their resistances were found, and they were placed on the circuits available in the laboratory as follows:

Nos. 1 to 6 inclusive. Alternating ∼ = 250.
" 7 " 9 " " ∼ = 132.
" 10 " 14 " Direct ————

These fuses were subjected to the action of the current for periods ranging from 83 to 487 hours—this variation being due to the fact that the circuits were used intermittently for lighting and for general laboratory purposes. From time to time additional resistance measurements were made. In the original report the change in resistance is exhibited graphically by means of curves. These curves are so widely different in form that their interpretation becomes a difficult matter, and the determination of any law impossible. They indicate, however, that a distinct rise in resistance occurred in all of the fuses on alternating circuits except No. 6, which shows a somewhat anomalous behavior. The maximum rise occurred in the case of No. 8, amounting to 29.6 per cent. in 105 hours. Of the fuses on direct current circuits, all but one showed a slight decrease in resistance, the maximum change being only 3.5 per cent. The figures for each specimen appear in a succeeding table.

That some molecular change actually took place was shown in the following way: It being practically impossible to test wires of so soft material for tensile strength, it was considered best to subject them to an alternate torsional stress of a given amount, continuing the alternations and noting the number until the specimen gave away. A simple piece of apparatus was constructed for this purpose, and it did its work very well. Twenty pieces of each of the fourteen specimens were tested in this way. Ten of these had been subjected to current action, and ten had not. The change in brittleness in the case of the fuses which had been on alternating circuits was quite marked, being in no case less than 7 per cent., while the change in those which had been on direct circuits was, with one exception, negligible. These results, together with some data on the fusing points before and after the passage of the currents, are given in the subjoined table:

No.	Rated Cap.	Fusing Current. Before.	After.	Per ct. Change	Torsion Test. Before.	After.	Per ct.	Hours Run.	Per ct. Change Resist.
1	2	8.83	8.56	3.06	14.4	10.9	24	487	0.2
2	2	7.96	7.86	1.26	21.6	19.9	7.9	169	0.5
3	3	12.6	12.15	3.56	14.9	13.2	11.14	487	15
4	3	8.46	8.24	2.6	28.8	22.4	21.4	169	0.4
5	5	17.96	17.46	2.55	21.7	18.5	14.8	170	2.2
6	10	27.4	25.3	8.3	13.3	11.7	12	487	2.0
7	18	52	46.4	10.8	14.8	11	26.4	209	11.3
8	36	52	45.4	11.9	15.2	18.6	10.5	105	29.6
9	18	52	49.5	4.8	16.9	18.9	17.8	88	3.5
10	10	26.8	26.8	.3	24.1	23.9	.8	170	−2.9
11	18	52	51.5	.9	13.8	13.7	.7	200	−3.5
12	18	52	51.4	1.1	13.8	12.3	10	296	−0.1
13	25	65.06	65.02	.061	11.1	11.0	.9	300	−2.8
14	25	65.06	65	.092	11.4	11.3	.8	264	−1.5

While these results may be considered as only a beginning along a line of work which is of both theoretical interest and practical value, yet they would seem to warrant the following conclusions: (1) There is a distinct although irregular rise in the resistance of a fuse on an alternating circuit. (2) This is perhaps to be accounted for by a change in the molecular structure of the metal. (3) This results in a decided lowering of the fusing current, in some cases at least easily sufficient to affect the reliability of the fuse.

A Brief Glance at Electricity in Medicine.

The Properties and Applications of the Different Currents.

Changes in Modern Practice of Electrical Treatment.

BY DR. W. J. MORTON.*

Electricity presents itself to physicians for medical use in three conventional modalities, termed respectively Galvanism, Faradism and Franklinism. The electrical engineer knows no such terms; to him electricity differs in volts and amperes only. And practically we also work upon the same lines. But time-honored uses and convenience justify us, I think, in retaining for the present our crude classification, since our apparatus consists almost entirely of voltaic cells, volta induction coils and electrostatic machines.

From the galvanic battery we obtain a high current strength and low voltage; the current is continuous or constant, though often used also as an interrupted current. Its effects upon the human tissue are mainly electrolytic and cataphoric—the tissue is affected chemically and physically, just as inert matter would be, and, in addition, is affected physiologically; the thousandth part of an ampere, viz., a milliampere, is the practical unit, and therapeutic dosage is expressed in terms of *n* milliamperes passing for *n'* minutes. Current strength is measured by a milliampere meter. Administrations are percutaneous, and through the mucous membrane, or by needle puncture. In the former case, the resistance offered by the skin is high—varying from one thousand to forty thousand ohms—and we require from 40 to 60 high voltage cells to overcome it. Two important features come into play—one, current density, which is a question of the size of the electrode, and the other the practical fact that the degree of pain excited in the nerves of the skin with accompanying injury to the skin erects the real barrier to increasing the current strength. Ten milliamperes to a square inch of skin is about the limit of endurance, and from 15 to 25 an average percutaneous current. Current density is therefore as essential an element of expressing the dosage as is the reading of the needle, for it is evident that, having 10 milliamperes to a square inch, the electromotive force and resistance remaining the same, an electrode 10 square inches in area would afford a galvanometer reading of 100 milliamperes. Physicians rarely mention the size of their electrodes, and should reform in this respect.

From a faradic apparatus or induction coil we obtain a current of much greater electromotive force but of decreased current strength. The salient feature of this current is that it is an interrupted current; from the primary winding of the coil is obtained a pulsating current—its flow is always in one direction, thus resembling an interrupted galvanic current, plus the current of its self-induction and that of the magnetic induction of the iron core. From the secondary winding is obtained an alternating current, whose electromotive force may be very high. An instrument to measure this current is greatly to be desired.

From a franklinic apparatus or electrostatic machine we obtain a current of enormous voltage and very low current strength. The physical and physiological effects are largely due to electromotive force and instantaneousness of current flow rather than to current strength.

There is still another form of electric manifestation of energy, which is a newcomer to electrotherapeutics—in fact, in its present guise a newcomer to electrical science; I refer to high frequency, high potential currents.

They fall out of line of our medical classification, for they are neither faradic nor franklinic alone—their production requires alternating current dynamos, transformers and condensers, they far transcend our volta induction coil products in frequency of interruption and electromotive force and our franklinic machines in current strength.

The fame of the high frequency high potential current is already invading the quiet domain of electro-therapeutics, and it is to that branch of our subject that I shall ask some attention tonight.

From the great initial difference in voltage, amperage, and absence or presence of interruptions of the three forms of current in medical use arises a corresponding difference in their physical and physiological effects upon the human organism, and from a study of these differences the physician must decide upon which form of current to use in given cases.

In using electricity to cure disease the physician may be said to resemble a huntsman who has a certain number of arrows in his quiver, each adapted to different purposes. He selects an arrow—a property of the current—some special thing it will do, and projects it against a disease or morbid condition. At least this is what he should do, but it is unfortunately a fact that physicians are wofully ignorant about what electricity will do upon inanimate matter, and more so upon what it will do upon animate. The general impression seems to be that electricity is to be injected into a human being by a small sponge electrode much as one would inject a medicated fluid in through the skin by a hypodermatic needle, and that the electricity was then to run about the system, hunt up the diseased spot, make a diagnosis, and chase out the disease, much as a ferret might run a rat out of a hole. I am not sure that this is not the idea of the electrical engineer.

Heat may be employed indirectly to heat small metallic loops with which surgical operations may be performed. This is known as galvano-cautery.

The actual heat produced in the body by its resistance to currents of the current strength commonly in use is inappreciable.

The franklinic current modifies bodily temperature, according to my experiments, in a marked degree.

High frequency high potential currents raise the temperature of the body.

Light may also be used indirectly in incandescent lamps to illuminate the cavities of the body—to transillumine the tissues, and thus detect foreign bodies, or dead tissue; it has also been used successfully to cure neuralgia.

The magnetic property of currents is also indirectly made use of to actuate mechanism, like surgical drills and saws, to cause mechanical vibration, transferred to tissue, etc.

Magnetism itself, whether from permanent magnets, the most powerful of electromagnets, or from solenoids, seems to have little or no effect upon the human tissue. The wonder is that it has ever been expected to have such an effect, since no one would select the ingredients of a human body as suitable ones to collect the electromagnetic lines of force. Possibly its advocates select patients of an initial iron constitution.

Induction effects due to the passage of currents through the body have received little attention. It must be supposed that there are a very great number of closed inductive circuits.

Chemical or Electrolytic. This is one of the most important properties of the current, and in connection with it a passing glance must be given to the nature of the electrolyte. The human body, for practical purposes of the administration of electricity may be considered as a semi-fluid mass, whose conducting power is due to its salts, held in solution. As a conductor of electricity, it is practically about a two per cent. solution of common salt. It is at once evident how important a part electrolysis, or chemical decomposition, and cataphoresis, or electric transfer of fluids, must play in this human electrolyte.

And, finally, we cannot close our leaflet upon electrolysis without a word in regard to one of the greatest extensions of electricity into the domain of medicine, that of the treatment of diseases peculiar to women by the methods devised and advocated by Apostoli, of Paris. The labors of Apostoli have worked a revolution in gynecological practice by means of a dispersing pad electrode whose current density is large applied externally on the skin, and a small metallic electrode whose current density is small applied internally.

Next to electrolysis, cataphoresis is undoubtedly the most important property of the galvanic or continuous current. Human tissue is well adapted to cataphoric action. Fluids flow to the negative pole and remain there owing to the membranous character of the meshes of tissues which inclose them and which resemble in this respect the porous diaphragm. Like electrolysis, cataphoresis is inseparable from every application of the continuous current. In inflammatory exudations of all kinds, in rheumatic thickenings of tissue, in tumors like fibroids of the uterus and others, the fluid in the mass is increased by the negative pole, thus creating a physical change, while by electrolytic decomposition the same diseased tissue is impoverished in the salts so essential to its vitality.

---

* Abstract of lecture given at Columbia College before the New York Electrical Society, May 17, 1893.

Cataphoric Medication. The cataphoric property of the current renders available, also, a very interesting practice of introducing medicines into the human body and blood stream through the skin or mucous membrane.

The reverse statement is interesting, and that is, that by cataphoric demedication medicines, like, for instance, arsenic and mercury, may be removed from the patient, and be visibly deposited upon the negative electrode according to the usual rules of electroplating.

PHYSIOLOGICAL PROPERTIES OF THE CURRENT.

The gross physiological phenomena with which we are familiar is that muscles are caused to contract. If the electrical impulse is instantaneous, the contraction is instantaneous, and immediately subsides. Up to about twenty impulses per second this rule holds good, but beyond that the muscle has not time between the impulses to subside from its state of contraction, and remains in permanent contraction so long as the varying current continues to flow. The excitation of the muscle is primarily effected by means of the nerves which supply it, but it may also be caused to contract independently of its nerves. Using a galvanic current, muscles contract more or less quickly to single impulses, according to which pole is used, and according to whether the circuit is made or broken.

Nerve Excitation. The nerves of the body are mainly of two kinds, the motor, which convey outward from the brain and other centres those neutral impulses which lead to muscular movement, and the sensory, which carry inward to the brain and other centres the sensations of pain, touch, temperature, etc., from the external world.

Electricity affects both classes of fibres, as well also as the special cellular nervous substance in which they start or in which they terminate. The positive pole diminishes the excitability and the conductivity of a nerve while the negative pole heightens them. The former is therefore sedative, as for instance, in neuralgia, while the latter is stimulating, as in a paralysis.

Again, living muscular tissue becomes acid by fatigue, and alkaline in repose or rest. It is evident that a positive pole will increase fatigue by increasing acidity, while the negative pole will overcome fatigue by neutralizing the acid.

Electricity enables the physician to decide if the muscle and its nerve is impaired, and adds greatly to the certainty of a diagnosis. The test is simple. An electrode is applied at a point on the skin previously determined and mapped out on charts, by aid of dissections upon the dead subject just over where the nerve plunges into the bulk of the muscle; if the faradic or induced current is turned on, it will be found that the muscle, if degenerated, has lost in a greater or less degree its power of contracting, simply because in its changed condition no single electric impulse lasts long enough to affect it.

If the galvanic or continuous current is turned on, the muscle contracts to single impulses, because they last longer, but this singular fact now appears, viz., that, whereas in the healthy muscle the negative pole causes the greatest contraction, in the diseased muscle the positive pole causes the greatest contraction.

Nutrition. No general fact associated with the administration of electricity is more familiar than that the general health, the nutritional processes, are promptly and greatly improved. The exchanges between the blood and the tissues are augmented, the patient absorbs more oxygen and excretes more carbonic acid and urea, and he gains in weight and comfort.

The trouble is, not that electricity does so little in our human bodies, but that it does so much we cannot classify, systematize and properly direct our power. We pause confused in the multiplicity and in the interwoven character of tissues and their functions, become bewildered in the problems of biology, the processes of vitality, the processes of disease. If we falter, let us not blame our noble agency, which is more than ready to do all that we require of it, but blame rather the shortcomings of our own knowledge.

In using the Influence machine the patient is placed upon an insulated platform by the older and classical method; or uninsulated by my method of employing condenser currents. The platform in the former case is connected to whichever prime conductor is desired, commonly the positive. He is now simply an extension of the conductor, and enlarges its static capacity.

In this position the static charge escapes from the charged patient either by leakage, by a brush discharge established by a pointed electrode, or by a disruptive discharge or spark, established by a ball electrode.

The electrodes are provided with insulated handles, and their conducting portion is attached to a chain which is in turn attached to the other prime conductor in the direct method, or led to the ground in the indirect method.

The direct method is commonly employed, but gives a painful, irritating spark, and should never be used. The indirect method, by grounding, gives a long, clear spark, and is by far less painful.

In working with electricity of this high E. M. F., the mere act of grounding seems to me to be superior, because it affords a large capacity surface in surrounding objects, rather than because it supplies an earth circuit in the ordinary acceptation of the term.

When the patient is treated by the static induced current, the output of the machine at its terminals is simply a current, and no longer a spark. The patient is not submitted to a "charge," but is treated as if by a galvanic or faradic apparatus.

PHYSICS AND PHYSIOLOGICAL ACTION.

The lightning is a great spark; its effects are mechanical, physical and physiological. Mechanically it often moves great masses, displaces and transports them; it performs, in short, on a large scale a cataphoresis, just as on a small scale we transport medicines through the skin, or move about fluids in the tissues. The spark of an Influence machine produces a molecular perturbation at every point where it strikes, a sort of molecular gymnastics, so to speak, or displacement of tissue parts, accompanied by corresponding changes in nutrition—new blood flows to the part, the lymphatics increase in activity, and carry off effete material; there is a local revivification.

Again, the great spark kills people, and upon their bodies are found marks indicating mechanical rupture of their tissues. If they recover, there frequently remains extensive paralysis of parts of the nervous system; if they die, no evidence of the cause of death is ascertainable beyond the organic injury mentioned. What has caused their death? The same question has been asked, and not yet answered, in regard to the death of criminals "electrocuted," and in regard to "linemen" who fall from a telegraph pole, shocked by the electric current. Picture to yourselves the amœba, the little cellular organism, and recall the experiments which demonstrated that with successive severe shocks of a varying current the amœba first assumes a spherical form, and then perhaps regains it, but finally remains, as the shock is increased, without power of motion. Live protoplasm has, in short, become dead protoplasm; the living animal has become a dead animal; the effect of an electric shock has been to deprive the protoplasm of the power of contractility.

HIGH FREQUENCY, HIGH POTENTIAL CURRENTS.

In view of the prodigious progress of electrical science and progress in recent years, it is evident that medicine, conservative as it may be, cannot long remain without the pale of the new advances. No one science can stride forward without dragging the others with it. There is a correlation of sciences, just as there is of energies. To-day medicine is occupied—is preoccupied—with bacteriology. And no less fascinating is this study than substantial the benefits which it has already conferred upon humanity. Electricity in medicine has had its "inning," and an unsatisfactory one. Its advent was premature, the nature of the agency itself and its phenomena were uncomprehended, and electro-therapeutics became a synonym for a "vasty deep" of speculative deductions, ignorant methods, and more unfortunately still, of crafty practices of charlatanism and quackery. The old electro-therapeutics still labors under antiquated physics, confused electro-physiology, and observations colored by the fancies of the observer; the new is being built upon experimentation in the physiologist's laboratory, and in the electrician's. The old relied upon *local* applications at the tip of small sponges—by local treatment it sought locally to cure disease; the new, while not neglecting the localizing method, goes further, and by a general application affects the entire organism, the pulse, the temperature, the lungs, and the excretions; in short, all that constitutes the nutrition of the individual. It seeks by exciting the highest degree of the health of the individual to make human tissue an unfit habitation for disease and morbid conditions.

The Morton currents of high frequency and high potential were described and published in 1881. The Influence machine has relatively little energy as compared with the Rumpfkorf coil, since so successfully used, or a primary circuit supplied by an alternating dynamo, and hence, Influence machines required to produce the condenser currents, in order to give good results had two Leyden jars attached to the prime conductors, so that their respective inner coatings were in connection with the respective prime conductors. To the outer coatings was attached a circuit of highly insulated wire, either in solenoid or straight form. The current was taken from the induction current. To produce and to regulate the strength of the current, the discharging rods were approximated to a point where sparks continuously passed.

Any of the ordinary forms of electrodes may be attached to the terminals, and the current may thus be used externally and internally as in ordinary galvanic and faradic administration. Owing to the relatively minor degree of pain it produces, while still producing strong muscular contractions, and the cubic area through which it acts, it is peculiarly useful in reaching into the deeper parts of the body, as for instance when it is desired to reach the brain, spinal cord and internal organs. I have found it of great value in diseases of the brain, spinal cord and nerves, in rheumatism, gout, goitre, etc.

Starting from this fundamental fact that when a current passes through the human organism the excitations are due to variations in its strength, D'Arsonval first studied the effects of a single wave of known form and then the effects of periodic waves. For careful physiological investigation his first form of apparatus was an alternating dynamo without iron, capable of furnishing 10,000 alternations per second. The current thus produced was passed through the primary of an induction coil having no iron core. With low frequencies neither pain nor muscular contraction was produced, but the current thus generated increased the tissue absorption of oxygen and the excretion of carbonic acid. It also acted as a sedative to pain.

He next adopted the method involving the continuous discharge of sparks between the discharging rods of a powerful Rumpfkorf coilconnecting two Leyden jars to each terminal by their interior tinfoil coatings, and connecting their outer coatings by a thick copper wire solenoid of from 15 to 20 turns. A wire led off from each end of the solenoid furnished the currents for his experiments in extreme frequency.

We are now entering upon the new era of the non-medicinal treatment of disease, especially chronic diseases. The leaven that has worked toward this end was implanted in this country away back in 1860. by one of the ablest men of his day, Dr. Jacob Bigelow, of Boston, in a treatise upon "Nature in Disease." It was a protest against expecting that every disease had its medicinal antidote. The days of a general and comprehensive antidotal treatment are numbered. The first dawns of light were the recognition that many diseases were self-limited, and could be left largely to Nature's processes. Then came the recommendations for fresh air, for exercise out-of-doors, for congenial surroundings, and appropriate food. Next the recognition of the importance of massage, of Swedish movement, of hydrotherapy and of electricity, viz., of treatments which essentially produce an increased demand for the oxygen of the air, for an increased capacity on the part of the blood to convey it to tissue, and a correspondingly increased oxidation of the tissue and assimilation of food. The patient's "respiratory circulation" is improved, consequently his nutrition improves, and finally his so-called disease disappears. Electricity leads the way in the advance; its dosage is measureable with precision; its effects are equally precise; they constitute the objective evidence of the treatment, viz., acceleration of the heart action, of the blood circulation, regulation of the temperature, and increased absorption of oxygen, with a corresponding increase of waste products like urea, creatinin, carbonic acid and water.

The law of life is motion—light, heat, chemical affinity all are motion; possibly material matter itself is ether in motion; the processes of life are chemical processes, the resultant energy developed is the mechanical force displayed by our muscles, the neural impulses conducted by our nerves the action of what we call our mind. Muscles, nerves and brain are but organic foci for the development of these energies by physical processes.

Electricity, judiciously employed, promotes the activity of the physical processes underlying life and health. It may even constitute the motive power which drives the machinery of life. Be that as it may, we know that we can alter the running of the vital machine for weal or for woe by turning an electric current in upon it.

We physicians, when we use electricity, are also electrical engineers; but our workshop holds its problems of health and of life and death. Do you, the members of this Society, ever pause to realize that you are relieved from this responsibility? Do you wonder that those who would grasp this problem are ever striving for aid, and that you, with your trained minds and special researches, may be of vast aid?

Are not our pathways parallel and often harmonious? That they may be, is my devout wish.

World's Fair Notes.

The third week of the Exposition since its opening day finds the majority of the exhibitors in the electrical section still at work on their exhibits. On the main floor of the Electricity Building not over a dozen exhibits are in place and complete for inspection by the throngs of visitors that are in daily attendance. The blame for this delay is hard to trace out, as one department points to the other when an explanation is sought. The value of each exhibit as an advertisement to the company making the display will be lessened by one month's time unless more progress is made in the next week than during the past three weeks. The exhibitors who have completed their display are making vigorous protests to the Chief of the Electrical Department about the delay in their neighbors' exhibits keeping visitors away from the section of the building in which they are unfortunate enough to be located.

The construction department has put the greater part of their wiremen to work stringing wires and hanging lamps in that portion of the Park known as Midway Plaisance. The managers owning the different concessions have made a number of protests against being left in darkness while the rest of the Park is brilliantly illuminated. Current has at last been turned into the mains leading to the Transportation Building. This is the last one of the Exposition buildings proper to be connected with the generating station. It is now expected that exhibitors will do the greater portion of the work on their uncompleted display after dark.

One of the most interesting dynamos of the direct coupled type, exhibited in the generating station in Machinery Hall, is that built by the European firm of Siemens & Halske. The machine has a capacity of 1,000 horse power and generates its current at a pressure of 500 volts. The armature shaft is coupled direct to the crank shaft of a triple expansion vertical engine of the marine type built by F. Schichaw, Elbing, Prussia. The current generated by this machine is transmitted to the Wooded Island, the German Village and the German exhibit in the Electricity Building. The firm of Siemens & Bros., of London, is installing an 18 kilowatt direct coupled dynamo as a portion of the British display in the Machinery Hall.

The American Bell Telephone Company's display in the south end of the Electricity Building is undoubtedly the leading attraction for visitors in that portion of the building. One of the entertaining features is a loud talking telephone, which can be distinctly heard in any part of their booth. The company have placed a long distance telephone directly connected with New York City at the disposal of the visitors.

Boston Notes.

Monday, June 5, is the day appointed for a hearing in the United States District Court at New Haven, Conn., of the case of John Cheney, of New Jersey, who is suing for an injunction against the directors of the Winchester Avenue Electric Railway, restraining them from using certain devices which Cheney claims belong to him. It is generally supposed that this is the next step in the litigation begun by the General Electric Company against the Westinghouse Company.

The street railway track between Beverly and Danvers, Mass., has passed into the hands of the Lynn and Boston Railroad Company.

The Swedish Electric Singers, a company of accomplished vocalists composed of employees in the General Electric Company's factories at Lynn, are to take part in the Singing Festival at the World's Fair, Chicago, July 21, 22 and 23.

Work is progressing on the extension of the Qunicy & Boston Electric Street Railway to North and East Weymouth. Hitherto the company has hired power from the local electric light company, but it has been decided to erect a large power station near Quincy Point bridge, and the undertaking will commence shortly.

The Legislative Committee on Mercantile Affairs has reported a bill to the Massachusetts Legislature in favor of placing underground all electric wires but the trolley wire, which has been omitted from the bill, it is believed, because of the opinion that the trolley wires will be entirely superseded in a few years at most.

Two recent fires in Boston played havoc with the establishments of at least three electrical concerns, and singular to say these fires occurred the same night. The building where the Electrical Forging Company has its extensive works, corner of Oliver street and Atlantic avenue, came near being gutted Sunday night about nine o'clock. The flames were extinguished but the deluge of water ruined a good deal of property. Between two and three o'clock in the morning fire was discovered in Fort Hill Square, only a block away, and before the flames could be subdued something like $100,000 damage had been done, including the utter ruin of the extensive and finely equipped laboratory of the Massachusetts Electrical Engineering Company and the works of the Shawmut Fuse Wire Company.

A length of wrought iron gas pipe was shown the writer a day or two ago that after a very short term of service underground had been entirely destroyed by electrolytic action. It was badly corroded throughout its entire length, while every two or three inches were holes from one inch to two inches long and up to three-quarters of an inch wide. When one considers the quantity of gas escaping by way of such a disintegrated pipe it is not to be wondered at that Bostonians are becoming somewhat alarmed and demand that the West End Railroad shall do something to stop the danger.

The attention of capitalists and street railway men in all parts of the country is turned to Boston at present, where the storage battery problem is being discussed by lawyers, judges, legislators and experts.

General News.

What is Going on in the Electrical World.

Boston, Mass.—Ground was broken last week for the new battery shop for the Hopedale Electric Company.

Toronto, Can.—The Toronto and Scarboro electric railway is nearly fully equipped and ready for opening.

Baltimore, Md.—The Carey Street railway has been completely equipped with electricity, and the horse cars removed.

Scranton, Pa.—The contract for the construction of the roadbed for the electric railway to Carbondale has been awarded.

Harmony Grove, Ga.—The company which is to erect cotton mills here intends to put in an electric light plant and run it in conjunction with the factory.

Buffalo, N. Y.—The American Electric Supply Company was awarded the contract for a dynamo and other electrical apparatus required by the new fire-boat.

Hoboken, N. J.—The North Hudson Railway Company have applied to the city council for permission to apply the trolley system to all their surface lines.

Rahway, N. J.—The work of constructing the electric street railway is now in progress. The road is expected to be in full operation by the 1st of August.

Carondelet, Mo.—It seems probable that the Sixth Street electric railway will be extended to Jefferson Barracks, a distance of three miles from the present terminus.

Wyandotte, Mich.—The extension of the Wyandotte and Detroit River Electric Railway from this city to Trenton will be completed about the 1st of June.

North Bergen, N. J.—The Township Committee has granted the application of the North Hudson Railway Company to run electric cars on Bergenline avenue.

Pensaukin, Pa.—The wires of the Merchantsville Electric Light Company will probably be extended to Pensaukin, in response to the demand of the people for electric light.

Montreal, Can.—At a late meeting of the directors of the Bell Telephone Company it was decided to increase the capital of the company from $2,200,000 to $2,640,000.

Jersey City, N. J.—The directors of the Jersey City and Bergen Railroad have decided to introduce electricity as a motive power on all the lines in Jersey City as soon as possible.

Kirkwood, Mo. — The Suburban Electric Lighting and Power Company of St. Louis have been granted a franchise to construct and maintain an electric plant in Kirkwood.

Quincy, Fla.—W. H. Ellis, A. L. Wilson and H. L. Shaw have been appointed to enter into communication with parties desiring to contract for furnishing electric light to this place.

Havre de Grace, Md.—A committee of council have been investigating the workings of the electric light plants in neighboring towns to aid them in determining on the establishment of a plant here.

La Junta, Col.—The plant of the electric light company was completely destroyed recently by the explosion of one of the boilers. Two of the employees were killed. The plant was valued at $20,000.

Jackson, Miss.—W. E. Hayne, of Jackson, W. R. Gravely, of New Orleans, and their associates have been granted a franchise by council to lay tracks and run electric cars in six specified streets in this city.

Ogden, Utah.—The city council has passed an ordinance extending the franchise of the Salt Lake and Ogden Electric Light and Gas Company for twenty-five years. Upon this measure depended a large number of extensive improvements.

Middletown, Md.—The prospects for the proposed electric railroad between Middletown and Frederick are brightening. The right-of-way has been secured along the national pike, and options have been obtained for the terminal points.

Pittsburg, Pa.—The Suburban Rapid Transit Company intends to extend its line to connect the South Side with White Hall, and has made a contract with the Westinghouse Electric and Manufacturing Company for a number of 30 H. P. motors for new cars.

Richmond, Va.—The Richmond Railway and Electric Company have just purchased the property known as Brown's Island, and will erect a building and remove their plant thither. Additional apparatus will be put in, and many improvements made in the equipment.

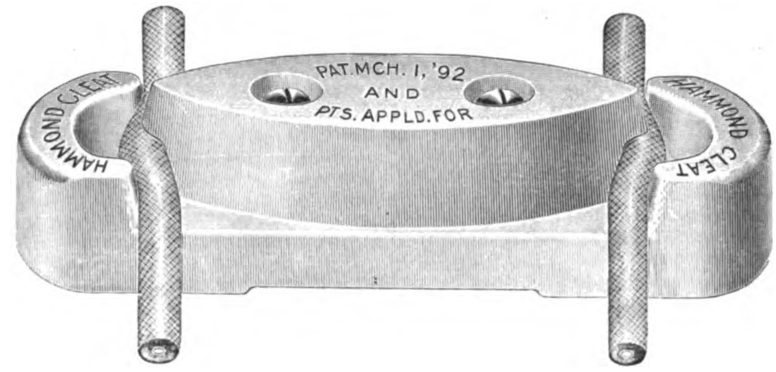
Woonsocket, R. I.—When the street railway lines in Woonsocket and Blackstone are equipped with electricity, the Blackstone line will be extended to Millville and probably to the Uxbridge town line. It is expected that the Blackstone line will be running by electricity by July 1.

Saranac Lake, N. Y.—Work on the Saranac and Lake Placid Railroad has begun, and will be completed by the middle of July. The building of this road is thought to ensure the construction of a road to the top of Whiteface Mountain. Charles E. Arnold, president of the Saratoga Electric Railroad, is to be president of the Saranac and Lake Placid line, and Jesse L. Mott will be chief engineer.

Parkersburg, W. Va.—The Parkersburg Gas and Electric Company, lately reorganized, having purchased the franchise and electric plant of the old company of the same name, will put in $12,000 in improvements. The officers elected are the same as those of the old company, viz.: President, C. H. Shattuck; vice-president, J. V. Rathbone; treasurer and secretary, J. M. Jackson, Jr.

Waukegan, Ill.—Contracts have been let for an electric street railway, for the accommodation principally of employees of the Washburn & Moen Company.—The Washburn & Moen wire works at South Waukegan are undergoing extensive improvements, adding largely to their facilities. It is generally understood that the capacity will be doubled during the present season. The smelting of copper ore and the production of copper wire with making of steel ingots is contemplated.

Bethlehem, Pa.—The Philadelphia and Allentown Electric Railway Company have awarded to Silverman & Stern, of Philadelphia, the contract to build 17½ miles of railway between Allentown and Hellertown, at $15,000 a mile, or a total of about $255,000. Work is to be begun at once and the road must be finished and in running order by September 25. They will build a single track of railway, with turnouts between the northern limits of Allentown, along Fifth street to Lawrence, to Lehigh, thence through South Allentown, Salisbury, and Aineyville, to and through South Bethlehem, Lower Saucon, and Hellertown.

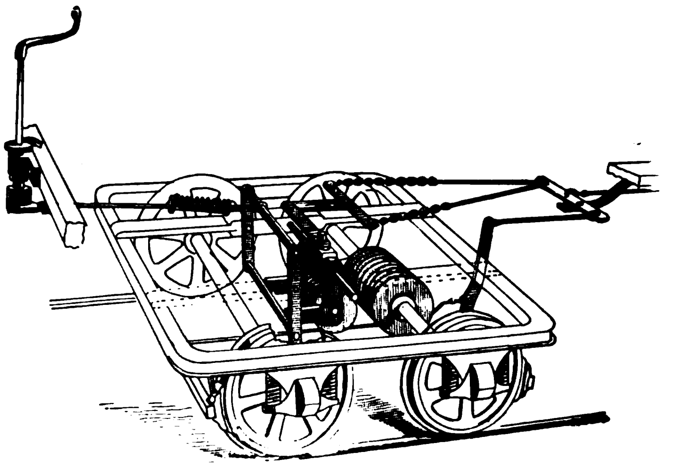


THE HAMMOND CLEAT.

The Hammond Cleat.

We publish herewith a cut of a new device that is destined to become very popular not only by reason of its own intrinsic merits which are many, but further, because it so admirably fills the conditions laid down or imposed by fire underwriters all over the country. As will be seen, this cleat is made in a single piece of the finest grade glazed porcelain, and being simplicity itself in design, it furnishes the quickest and easiest method of wiring possible. By its use the unsightly tie wire is unnecessary, and can be supplied with one, two or three openings which are adapted for receiving all the ordinary sizes of wire without injuring the insulation. Its unique character enables it to hold the wire firmly, and as the wire binds on the insulator and not on the retaining points, all breaks are avoided, and what is more the slack is easily taken up, so that by its adoption and use the neatest, safest and best kind of wiring can be done.

All who are engaged in electrical construction work will promptly and fully appreciate the foregoing advantages, which mean greater economy by saving of time and material, and the preservation of the insulation intact, a most important consideration.



THE ELLIOTT CAR BRAKE.

Although a first class device in every respect, and made of the best quality porcelain, the Hammond Cleat and Insulator Company, 220 Devonshire street, Boston, sell it at a remarkably low figure so as to bring it within the reach of all.

The Elliott Car Brake.

Although there have been innumerable car brakes invented for street cars, the form generally in use to-day is one of the oldest.

The brake invented by Mr. G. R. Elliott, of Boston, Mass., is the embodiment of simplicity and efficiency, and is constructed on sound mechanical principles.

A chilled iron cylinder having a screw thread cut upon its surface is firmly fixed upon the axle of one pair of wheels of the truck of a car; a like cylinder of smaller dimensions is hung in bearings at the lower end of a lever frame in such a manner as to bring it parallel to that upon the axle; the fulcrum of this lever frame is an iron rod having loose bearings in the woodwork of the truck frame, and with this rod the lever frame carrying the smaller screw cylinder reciprocates.

To the upper end of the lever frame is attached the rod leading to the brake handle, which rod is divided and has a spiral spring interposed at the junction in such a manner as to make the pull of the brake handle elastic.

A half turn of the brake handle draws this rod forward, causing the lower part of the lever frame which bears the small screw cylinder to move toward the larger screw cylinder fixed upon the axle of the wheels with which it engages and by which it and the lever frame carrying it are moved toward one side or the other of the car according to the direction in which the latter is moving. A link arm, one end of which is attached to the lever frame, and which moving with it is connected by its other end to the end of one arm of a three-armed rocking lever fulcrumed at the junction of its three arms and operating in such a manner that whichever direction the lever frame takes by reason of its small screw cylinder engaging with the screw cylinder on the axle, the three armed rocking lever will be moved so as to cause one of two links connecting two of its arms to an ordinary straight lever at one end of the touch frame to draw inward, thus causing the other end of the last mentioned lever to move outward carrying with it the rod connecting it with the beams of the brake shoes, and thus bringing the brake shoes against the tread of the wheels against the stress of springs which withdraw the shoes the instant the brake handle is released.

A very slight turn of the brake handle will bring the screw cylinders into engagement and the smaller cylinder will immediately begin to move in a direction at right angles to the length of the car and parallel to the axis of the axle upon which the fixed screw cylinder is located, and it will continue to move in this direction until the strain upon the brakes exceeds the pressure exerted upon the brake handle when it will disengage and fly back toward its former position, engaging again instantly with the excess of pressure, and repeating this action until the car stops. This is accomplished so rapidly that the effect upon the car is the same as would result from a continuous pressure of the brake shoes against the wheels, yet the several pressures have the effect of destroying the sudden jerk resulting from the locking of the wheels, and, while avoiding the friction and consequent flattening of the peripheries of the latter, is none the less effectual in bringing the car to a stop.

While putting on the brakes turns off the current, throwing off the brakes does not turn on the current, but leaves the car at a stand-still until the motor man chooses to start it, when the brakes are in a position not to retard its progress. It is also equally adapted to horse cars.

Considering the fact that the greatest power necessary under any circumstances only requires that the brake handle be turned one-half of a revolution, it is clear that the action of the brake is almost if not quite instantaneous, and that its lack of the rigid characteristics of the ordinary brakes makes the wear upon the wheels uniform.

Removal Notice.

We beg to inform our customers that owing to the recent fire in our office and factory at 161 and 163 High street, we have been obliged to remove our office temporarily to 85 Water street, and our factory and storeroom to 54 Pearl street, Boston.

We are well equipped in our new quarters, and shall have no difficulty in giving orders our usual prompt attention.

Thanking our customers for past patronage, we remain,

Yours very truly,

Shawmut Fuse Wire Company.

The Curtis Motor.

A trial of the Curtis railway motor has lately been made on the Morris Cove Road. New Haven, Conn. The trial was a thorough success, and the directors of the road, who were present, expressed their satisfaction. It is probable that the new motors will be placed on all the cars of this line, including the Winchester avenue branch.

COMMERCIAL PARAGRAPHS.

That there is merit in the Sterling Water Tube Safety Boiler is proven by the fact that during the last twelve months the company has sold 58,000 porse power, a showing that compares favorably with any boiler now on the market. And that the public is appreciating the high character of these boilers more and more is further proved by the fact that from the 5th to the 12th day of the present month of May no less than 4,000 horse power were sold. Mr. J. Bradford Sargent, 620 Atlantic avenue, Boston, who represents this popular boiler in the East, reports that the outlook for future business is even more promising than the past.

Since opening their new and commodious factory on Dover street, Boston, the Electric Gas Lighting Company has been in far better form than ever before for handling its ever growing business, but with increased facilities has come an increased demand for its varied specialties, with the result that already a feeling begins to be felt in every department as if partition walls were in the way, or additional floors would have to be leased ere long, if the demand continues as at present.

The Brown Electric Company, whose attractive and well stocked store, corner of Federal and Summer streets, Boston, contains about everything of an electrical nature, reports business as first-class in every department. This company is being appointed agent for several new electrical devices and is pushing them successfully.

The Consolidated Electric Manufacturing Company will have another of its unique 60-arc light machines, equipped with Elkins automatic regulator, running in its factory next week. Those already sold and in service to-day are making an excellent record for themselves.

Mr. G. W. (Happy) Adams, whom everybody knows as the genial manager of the Boston Electric Protective Association, which takes care of nearly $100.000.000 worth of property in Boston alone, has recently secured a patent on a watchman's lock which comes as near being perfection as any one could wish.

The Boston Motor Company, 17 Battery March street, Boston, has received the following letter from the proprietors of that popular paper, *The Youth's Companion:*

Gentlemen: We have carefully examined and tested the $1.00 motor which you manufacture and believe it to be superior to any other low priced motor now on the market. Our patent attorney has also completed his examinations and pronounces your claims valid and strong. We shall now be pleased to offer your motor as a premium in our premium list. Very truly,

Perry, Mason & Co.

The new W.-W. Lightning Arrester is gaining the best of success, and the Ansonia Electric Company, formerly the Electrical Supply Company, are prepared to furnish them in large quantities on short notice.

The Ansonia Electric Company, formerly the Electrical Supply Company, recently secured an order for the entire equipment of the Columbia [Missouri] plant for Stanley Transformers.

The recently organized firm of Acker & Loveland have moved into offices in the Monadnock Building, Chicago, and are now making a specialty of the General Incandescent Arc Light Company's lamps in the West and Southern States. They also have a number of second hand dynamos for sale.

The firm of Cutler & Hammer of Chicago have just received the contract for building the complete switchboard equipment, consisting of indicators, rheostats and switches for the American Storage Battery Company's factory which has recently been built. The C. & H. firm have also built the switchboard for the Columbus Building, one of Chicago's new sixteen story buildings.

The exhibit of magnet, line and rubber covered wire in the Ansonia Electric Company's booth at the World's Fair will give their customers some idea of the complete line of wire which they carry.

A handsome specimen of artistic work is the new catalogue of the Interior Conduit and Insulation Company. In addition to a description of the many devices applicable to interior wiring, the catalogue contains complete specifications for the installation of the Interior Conduit system and also a code for customers who may wish to order by telegraph or cable. The Johnson switch, the Lundell motor and all devices are constructed to conform to standards and are particularly applicable to the Edison system of distribution. As it is practically impossible to catalogue at any given time all the improvements and new developments, the Interior Conduit and Insulation Company therefore respectfully solicit inquiry as to any device, method or apparatus which may not appear in the catalogue before excluding them from the opportunity of supplying the same.

The Railway Equipment Company of Chicago have issued an elaborate catalogue, giving specific information to intending purchasers in this line. The list of supplies carried by this company includes everything needed for a complete equipment.

INCORPORATIONS.

The Piqua Electric Railway Company, Piqua, Ohio. Capital stock, $100,000.

North Chicago Electric Railway Company, to construct, lease, and purchase and operate horse, dummy and street railroads in Chicago and Cook County, Ill. Capital stock, $2,000,000. Incorporators: Charles H. Gurney, John E. Burke and Alexander M. Savage.

The Pumpelly-Sorley Storage Battery Company, Chicago. Capital stock, $500,000. Incorporators: Harriet M. Gibbs, Jessie Rowe, George H. Jenney.

The Frederick and Middletown Electric Railway Company, to erect an electric railway for passenger and freight traffic between Frederick and Middletown, Md. Capital stock, $125,000. Incorporators: L. N. Downs and Livingston Norman, of New York City; T. E. Bowne, of Brooklyn; George William Smith, C. V. S. Levy, U. A. Sharretts and E. L. Miller, of Frederick.

The Northwestern Electrical Manufacturing Company, at Milwaukee. Capital stock, $10,000. Incorporators: John Z. Westervelt, Daniel L. Case and Lee Peck.

The West Jersey Traction Company has filed articles of incorporation in Camden for the purpose of running a network of rapid transit trolley lines throughout Camden and Burlington Counties, N. J. The capital stock of the company is placed at $3,000,000. The incorporators are Heulings Lippincott, of the National State Bank, Camden; Howard Parry, of Cinnaminson; Mitchell B. Perkins and Henry Van Brunt, of Beverly; Samuel E. Stokes, Charles Tomlinson, George A. Aldrich, Dillwyn Wistar and John P. Logan, of Philadelphia.

The Monmouth County Sea Shore Electric Railway Company is about to file articles of incorporation with the county clerk at Freehold, N J. The capital stock of the company is $1,500,000, and J. C. Shafer, president of the Sea Shore Electric Railway, is said to be the leading spirit in the enterprise. The road contemplated will extend from Pleasure Bay, near Long Branch, to Point Pleasant, passing through Long Branch, West End, Elberon, Deal Beach, Loch Arbor, North Asbury Park, Asbury Park, Ocean Grove, Key East, Belmar, Spring Lake, Como and Point Pleasant.

The Texas Electric Burglar and Fire Alarm Manufacturing Company of Corsicana, Texas. Capital stock, $50,000. Incorporators: A. C. Sloan, A. T. Wood, B. Zadex and J. Schwartz.

The Waco Electric Railway and Light Company of Waco, Texas, has filed an amended charter increasing the capital stock to $300,000.

The Cincinnati and Covington Electric Railway Company, Covington, Ky. Capital stock, $25,000. Incorporators: F. P. Helm, John Dorsel, J. H. Mersman, J. J. Dulaney, W. B. Wilson, B. E. Talbott, O. J. Carpenter.

The Utica Subway Company of Utica, N. Y., to construct, excavate and maintain subways, ducts and conduits for laying, containing, holding and conducting telegraph, telephone, electric light, fire alarm, police and other wires, and electrical conductors underground, in the streets and highways of the city of Utica. Capital stock, $10,000. Directors: William B. Crouse, John R. Baxter, Thos. F. Baker, Clifford F. Marklove, Charles W. Mather, William W. Fowler, Horatio S. Moore and Francis M. Kendrick.

ELECTRICAL PATENT RECORD.

Letters Patent Issued May 16, 1893

ELECTRIC RAILWAYS AND APPLIANCES.

497,337. Overhead Electric Railway. William D. Patterson, Keokuk, Iowa. Filed Nov. 1, 1892.

497,356. Electric-Car Truck. George S. Strong, New York, N. Y., assignor to James N. Gamble, Cincinnati, Ohio. Filed Jan. 25, 1892.

497,377. Trolley for Conduit-Railways. Paul C. Just, Chicago, Ill. Filed April 20, 1892.

497,394. Conduit Electric Railway. George Westinghouse, Jr., Pittsburg, Pa. Filed April 8, 1892.

497,408. Electric-Railway Signal. William H. Jordan, Brooklyn, N. Y. Filed Sept. 10, 1892.

497,436. Sectional Contact-Conductor for Electric Railways. George Westinghouse, Jr., Pittsburg, Pa. Filed April 11, 1892.

497,585. Closed Conduit for Electric Railways. Archibald J. Martin, Philadelphia, Pa. Filed Sept. 13, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

497,438. Arc Electric Lamp. John C. Wray, Peoria, Ill. Filed March 21, 1892.

497,450. Electric-Arc Lamp. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Sept. 22, 1892.

497,491. Automatic Cut-Out for Electric Light Circuits. Charles Cuno, Wauwatosa, Wis. Filed April 16, 1892.

497,494. Electric-Arc Lamp. James Einstein, Munich, Germany, assignor to Paul Lemaire, New York, N. Y. Filed Nov. 23, 1892.

497,558. Electric-Arc Lamp. Frank H. Thompson, Philadelphia, Pa. Filed Jan. 19, 1892.

DYNAMOS AND MOTORS.

497,361. Commutator Brush-Holder for Dynamo-Electric Machines. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Nov. 2, 1891.

497,468 Dynamo-Electric Machine or Motor. Walter K. Freeman, Boston, Mass. Filed Nov. 3, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

497,335. Manufacture of Telephone Cables. William R. Patterson, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Aug. 24, 1891.

497,649. Magneto-Telephone. James P. Freeman, Washington, D. C., assignor to Marvin C. Stone, same place. Filed May 16, 1892.

MEASURING INSTRUMENTS.

497,448. Galvanometer. Adrian H. Hoyt, Manchester, N. H., assignor to the Whitney Electrical Instrument Company, same place. Filed May 9, 1892.

497,449. Galvanometer. Adrian H. Hoyt, Manchester, N. H.; assignor to the Whitney Electrical Instrument Company, same place. Filed May 9, 1892.

497,521. Electric Measuring-Instrument. Adrian H. Hoyt, Manchester, N. H., assignor to the Whitney Electrical Instrument Company, Saco, Me. Filed Nov. 14 1891.

497,522. Galvanometer. Adrian H. Hoyt, Manchester, N. H., assignor to the Whitney Electrical Instrument Company, Saco, Me Filed Nov. 14, 1891.

497,539. Electrical Measuring-Instrument. Oscar Frolich, Berlin, Germany, assignor to Siemens & Halske, same place. Filed Oct. 25, 1892.

MISCELLANEOUS.

497,310. Automatic Disconnector. William A. Cullen, Paterson, N. J., assignor to the Johnston Safe Automatic Electric Company, Richmond, Va. Filed Jan. 28, 1893.

497,331. Automatic Time-Stamp. Warren B. Martindale, Rochester, Ind. Filed June 30, 1892.

497,336. Insulating-Tape. William R. Patterson, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Aug. 24, 1891.

497,366. Rheostat. Parvin Wright, Denver, Col. Original application filed Jan. 16, 1892. Divided and this application filed Aug. 8, 1892.

497,397. Lightning-Arrester. Alexander Wurts and Chas. F. Scott, Pittsburg, Pa., assignors to the Westinghouse Electric and Manufacturing Company, same place. Filed Oct. 26, 1892.

497,404. Electric Cigar-Lighter. William P. Carstarphen, Jr., Denver, Col., assignor of two-thirds to James E. Gregg, same place, and Richard W. Webb, Santa Fe, N. Mex. Filed Aug. 17, 1892.

497,411. Push-Button Switch. Fred S. McGregory, Revere, assignor to John M. Orford, Boston, Mass. Filed Jan. 21, 1893.

497,430. Circuit-Protector. Harry W. Leland, Jersey City, N. J. Filed Aug. 6, 1892.

497,482 Shunt for Electric Light and Power Stations. Edward Weston, Newark, N. J. Filed Nov. 28, 1892.

497,489. Circuit-Controlling Device. John P. Buchanan, Boston, Mass., assignor to the Hall Signal Company of Maine. Filed Oct. 15, 1891. Renewed Oct. 22, 1892.

497,495. Electric Kink. Midbury V. Hassan, Rochester, N. Y. Filed May 28, 1891.

497,507. Lightning-Arrester. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Dec. 22 1892.

497,508. Lightning-Arrester. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Dec. 22, 1892.

497,509. Lightning-Arrester. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place Filed Dec. 22, 1892.

497,515. Insulator. Thomas H. Brady, New Britain, Conn. Filed Jan. 16, 1893.

497,535. Process of Manufacturing Electric-Conduit Sections. James F. Cummings, Detroit, Mich. Filed July 12 1892.

497,536. Underground Conduit for Electrical Conductors. James F. Cummings, Detroit, Mich. Filed July 28, 1892.

497,552. System of Conductors for Electric Fire-Engines. Joseph Sachs, New York, N. Y. Filed May 26, 1892.

497,563. Electric Pump-Governor. Charles R. Whittier, New York, N. Y. Filed Aug. 8, 1892.

497,621. Process of Electro-Tin-Plating. Louis Aronson, New York, N. Y., assignor of one-half to James H. Hoffman, same place. Filed Jan 31, 1893.

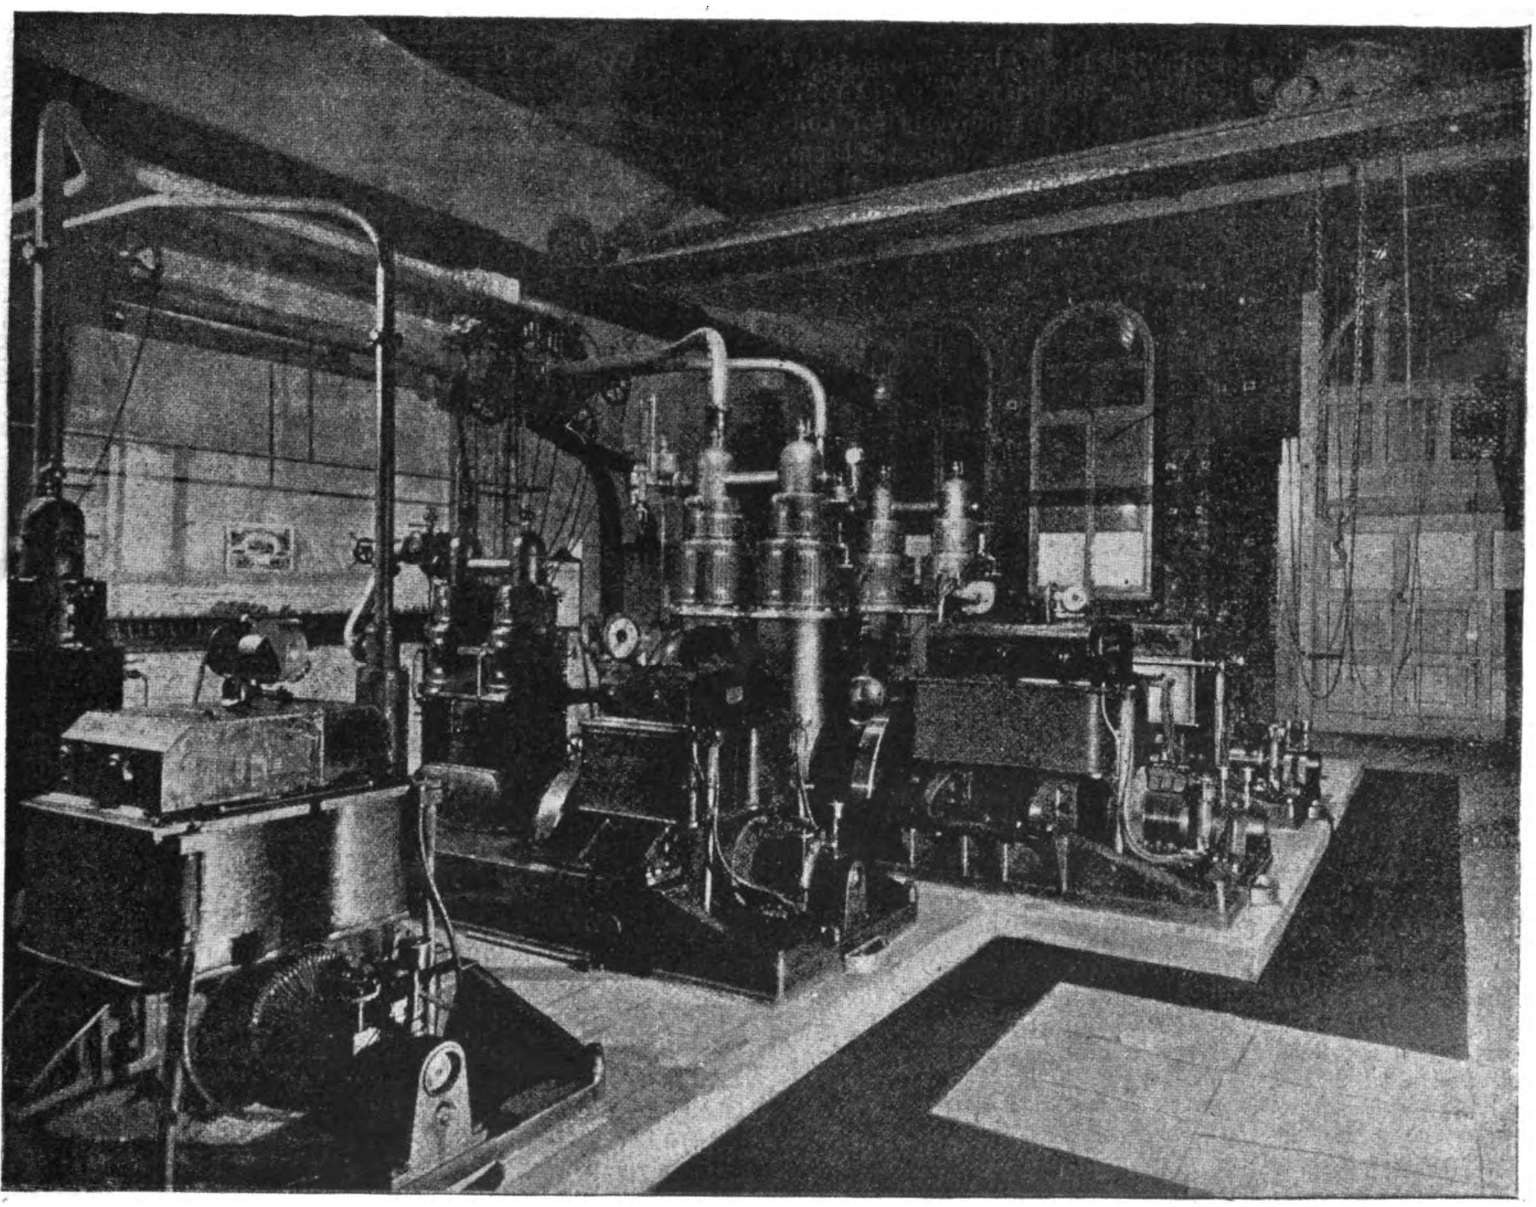
497,680. Safety Cut-Out Apparatus for Networks of Multiple Electrical Conductors. Paul Nordmann, Berlin, Germany, assignor to Siemens & Halske, same place. Filed Nov. 25, 1892.

497,755. System of Electrical Distribution. Waldemar Meissner, Konigsberg, Germany, assignor to Siemens & Halske, Berlin, Germany. Filed Oct. 23, 1889.

497,756. Circuit Switch. Ernst Woltmann and Harry A. Triggs, Denver, Colo., assignors to the Electrical Specialty Company, same place. Filed Jan. 17, 1893.

ELECTRICITY.

Vol. IV. New York. MAY 31, 1893. Chicago. No. 20



DYNAMO ROOM, HULL CORPORATION SUPPLY. (See Page 271.)

ON LIGHT AND OTHER HIGH FREQUENCY PHENOMENA.

INTRODUCTORY—SOME THOUGHTS ON THE EYE.

BY NIKOLA TESLA.*

When we look at the world around us, on Nature, we are impressed with its beauty and grandeur. Each thing we perceive, though it may be vanishingly small, is in itself a world, that is, like the whole of the visible universe, matter and force governed by law—a world, the contemplation of which fills us with feelings of wonder and irresistibly urges us to ceaseless thought and inquiry. But in all this vast world, of all objects our senses reveal to us, the most marvelous, the most appealing to our imagination, appears no doubt a highly developed organism, a thinking being. If there is anything fitted to make us admire Nature's handiwork, it is certainly this inconceivable structure, which performs its innumerable motions in obedience to external influence. To understand its workings, to get a deeper insight into this Nature's masterpiece, has ever been for thinkers a fascinating aim, and after many centuries of arduous research men have arrived at a fair understanding of the functions of its organs and senses. Again, in all the perfect harmony of its parts, of the parts which constitute the material or tangible of our being, of all its organs and senses, the eye is the most wonderful. It is the most precious, the most indispensable of our receptive or directive organs; it is the great gateway through which all knowledge enters the mind. Of all our organs, it is the one which is in the most intimate relation with that which we call intellect. So intimate is this relation that it is often said that the very soul shows itself in the eye.

It can be taken as a fact, which the theory of the action of the eye implies, that for each external impression, that is, for each image produced upon the retina, the ends of the visual nerves, concerned in the conveyance of the impression to the mind, must be under a peculiar stress or in a vibratory state. It now does not seem improbable that, when by the power of thought an image is evoked, a distinct reflex action, no matter how weak, is exerted upon certain ends of the visual nerves, and therefore upon the retina. Will it ever be within human power to analyze the condition of the retina when disturbed by thought or reflex action, by the help of some optical or other means of such sensitiveness that a clear idea of its state might be gained at any time? If this were possible, then the problem of reading one's thoughts with precision, like the characters of an open book, might be much easier to solve than many problems belonging to the domain of positive physical science, in the solution of which many, if not the majority, of scientific men implicitly believe. Helmholtz has shown that the fundi of the eyes are themselves luminous, and he was able to *see*, in total darkness, the movement of his arm by the light of his own eyes. This is one of the most remarkable experiments recorded in the history of science, and probably only a few men could satisfactorily repeat it, for it is very likely that the luminosity of the eyes is associated with uncommon activity of the brain and great imaginative power. It is fluorescence of brain action, as it were.

Another fact having a bearing on this subject which has probably been noted by many, since it is stated in popular expressions, but which I cannot recollect to have found chronicled as a positive result of observation, is, that at times, when a sudden idea or image presents itself to the intellect, there is a distinct and sometimes painful sensation of luminosity produced in the eye, observable even in broad daylight.

The saying, then, that the soul shows itself in the eye is deeply founded, and we feel that it expresses a great truth. It has a profound meaning even for one who, like a poet or artist, only following his inborn instinct or love for Nature, finds delight in aimless thoughts and in the mere contemplation of natural phenomena, but a still more profound meaning for one who, in the spirit of positive scientific investigation, seeks to ascertain the causes of the effects. It is principally the natural philosopher, the physicist, for whom the eye is the subject of the most intense admiration.

Two facts about the eye must forcibly impress the mind of the physicist, notwithstanding he may think or say that it is an imperfect optical instrument, forgetting that the very conception of that which is perfect, or seems so to him, has been gained through this same instrument. Firstly, the eye is, as far as our positive knowledge goes, the only organ which is *directly* affected by that subtle medium which, as science teaches us, must fill all space; secondly, it is the most sensitive of our organs, incomparably more sensitive to external impressions than any other.

The organ of hearing implies the impact of ponderable bodies, the organ of smell the transference of detached material particles, and the organs of taste and of touch or force the direct contact, or at least some interference of ponderable matter; and this is true even in those instances of animal organisms in which some of these organs are developed to a degree of truly marvelous perfection. This being so, it seems wonderful that the organ of sight solely should be capable of being stirred by that which all our other organs are powerless to detect, which yet plays an essential part in all natural phenomena, which transmits all energy and sustains all motion and, that most intricate of all, life, but which has properties such that even a scientifically trained mind cannot help drawing a distinction between it and all that is called matter. Considering merely this, and the fact that the eye, by its marvelous power, widens our otherwise very narrow range of perception far beyond the limits of the small world which is our own, to embrace myriads of other worlds, suns and stars in the infinite depths of the universe, would make it justifiable to assert that it is an organ of a higher order. Its performances are beyond comprehension. Nature, as far as we know, never produced anything more wonderful. We can get barely a faint idea of its prodigious power by analyzing what it does and by comparing. When ether waves impinge upon the human body, they produce the sensations of warmth or cold, pleasure or pain, or perhaps other sensations of which we are not aware, and any degree or intensity of these sensations, which degrees are infinite in number, hence an infinite number of distinct sensations. But our sense of touch, or our sense of force, cannot reveal to us these differences in degree or intensity unless they are very great. Now we can readily conceive how an organism such as the human, in the eternal process of evolution, or more philosophically speaking adaptation to Nature, being constrained to the use of only the sense of touch or force, for instance, might develop this sense to such a degree of sensitiveness or perfection that it would be capable of distinguishing the minutest differences in the temperature of a body even at some distance, to a hundredth, or thousandth, or millionth part of a degree. Yet, even this apparently impossible performance would not begin to compare with that of the eye, which is capable of distinguishing and conveying to the mind in a single instant innumerable peculiarities of the body, be it in form or color or other respects. This power of the eye rests upon two things, namely, the rectilinear propagation of the disturbance by which it is affected, and upon its sensitiveness. To say that the eye is sensitive is not saying anything. Compared with it all other organs are monstrously crude. The organ of smell which guides a dog on the trail of a deer, the organ of touch or force which guides an insect in its wanderings, the organ of hearing, which is affected by the slightest disturbance of the air, are sensitive organs, to be sure, but what are they compared with the human eye! No doubt it responds to the faintest echoes or reverberations of the medium; no doubt it brings us tidings from other worlds infinitely remote, but in a language we cannot as yet always understand. And why not? Because we live in a medium filled with air and other gases, vapors and a dense mass of solid particles flying about. These play an important part in many phenomena; they fritter away the energy of the vibrations before they can reach the eye; they, too, are the carriers of germs of destruction, they get into our lungs and other organs, clog up the channels and imperceptibly yet inevitably arrest the stream of life. Could we but do away with all ponderable matter in the line of sight of the telescope it would reveal to us undreamt of marvels. Even the unaided eye, I think, would be capable of distinguishing in the pure medium small objects at distances measured probably by hundreds or perhaps thousands of miles.

But there is something else about the eye which impresses us still more than these wonderful features which we observe, viewing it from the standpoint of a physicist, merely as an optical instrument—something which appeals to us more than its marvelous faculty of being directly affected by the vibrations of the medium, without interference of gross matter, and more than its inconceivable sensitiveness and discerning power. It is its significance in the processes of life. No matter what one's views on Nature and life may be, he must stand amazed when, for the first time in his thoughts, he realizes the importance of the eye in the physical processes and mental performances of the human organism. And how could it be otherwise, when he realizes that the eye is the means through which the human race has acquired the entire knowledge it possesses, that it controls all our motions—more still, all our actions.

There is no way of acquiring knowledge except through the eye. What is the foundation of all philosophical systems of ancient and modern times, in fact of all the philosophy of man? *I am, I think; I think, therefore I am.* But how could I think and how would I know that I exist if I had not the eye? For knowledge involves consciousness; consciousness involves ideas, conceptions; conceptions involve pictures or images, and images the sense of vision, and therefore the organ of sight. But how about blind men will be asked? Yes, a blind man may depict in magnificent poems forms and scenes from real life, from a world he physically does not see. A blind man may touch the keys of an instrument with unerring precision, may build the fastest boat, may discover and invent, calculate and construct, may do still greater wonders—but all the blind men who have done such things have descended from those who had seeing eyes. Nature may reach the same result in many ways. Like a wave in the physical world, in the infinite ocean of the medium which pervades all, so in the world of organisms, in life, an impulse started proceeds onward, at times may be with the speed of light, at times again so slowly that for ages and ages it seems to stay, passing through processes of a complexity inconceivable to man, but in all its forms, in all its stages, its energy, ever and ever integrally present. A single ray of light from a distant star falling upon the eye of a tyrant in bygone times may have altered the course of his life, may have changed the destiny of nations, may have transformed the surface of the globe, so intricate, so inconceivably complex are the processes of Nature. In no way can we get such an overwhelming idea of the grandeur of Nature as when we consider that in accordance with the law of the conservation of energy, throughout the infinite, the forces are in a perfect balance, and hence the energy of a single thought may determine the motion of a universe. It is not necessary that every individual, not even that every generation or many generations, should have the physical instrument of sight in order to be able to form images and to think, that is, form ideas or conceptions; but sometime or other, during the process of evolution, the eye certainly must have existed, else thought, as we understand it, would be impossible; else conceptions, like spirit, intellect, mind—call it as you may—could not exist. It is conceivable that in some other world, in some other beings, the eye is replaced by a different organ, equally or more perfect, but these beings cannot be men.

---

* A lecture delivered before the Franklin Institute at Philadelphia, Feb. 24, 1893, and before the National Electric Light Association at St. Louis, Mo., March 1, 1893.

Now what prompts us to all voluntary motions and actions of any kind? Again the eye. If I am conscious of the motion, I must have an idea or conception, that is, an image, therefore the eye. If I am not precisely conscious of the motion, it is because the images are vague or indistinct, being blurred by the superimposition of many. But when I perform the motion, does the impulse which prompts me to the action come from within or from without? The greatest physicists have not disdained to endeavor to answer this and similar questions, and have at times abandoned themselves to the delights of pure and unrestrained thought. Such questions are generally considered not to belong to the realm of positive physical science, but will before long be annexed to its domain. Helmholtz has probably thought more on life than any modern scientist. Lord Kelvin expressed his belief that life's process is electrical and that there is a force inherent to the organism and determining its motions. Just as much as I am convinced of any physical truth I am convinced that the motive impulse must come from the outside. For, consider the lowest organism we know—and there are probably many lower ones—an aggregation of a few cells only. If it is capable of voluntary motion it can perform an infinite number of motions, all definite and precise. But now a mechanism consisting of a finite number of parts and few at that, cannot perform an infinite number of definite motions, hence the impulses which govern its movements must come from the environment. So, the atom, the ulterior element of the universe's structure, is tossed about in space eternally, a play to external influences, like a float in a troubled sea. Were it to stop its motion *it would die.* Matter at rest, if such a thing could exist, would be matter dead. Death of matter! Never has a sentence of deeper philosophical meaning been uttered. This is the way in which Prof. Dewar forcibly expresses it in the description of his admirable experiments, in which liquid oxygen is handled as one handles water, and air at ordinary pressure is made to condense and even to solidify by the intense cold—experiments which serve to illustrate, in his language, the last feeble manifestations of life, the last quiverings of matter about to die. But human eye shall not witness such death. There is no death of matter, for throughout the infinite universe all has to move, to vibrate—that is, to live.

I have made the preceding statements at the peril of treading upon metaphysical ground in my desire to introduce the subject of this lecture in a manner not altogether uninteresting, I may hope, to an audience such as I have the honor to address. But now then, returning to the subject, this divine organ of sight, this indispensable instrument for thought and all intellectual enjoyment, which lays open to us the marvels of this universe, through which we have acquired what knowledge we possess, and which prompts us to, and controls, all our physical and mental activity. By what is it affected? By light! What is light?

We have witnessed the great strides which have been made in all departments of science in recent years. So great have been the advances that we cannot refrain from asking ourselves, Is this all true, or is it but a dream? Centuries ago men lived, thought, acted, discovered, invented, and believed that they were soaring, while they were merely proceeding at a snail's pace. So we too may be mistaken. By taking the truth of the observed events as one of the implied facts of science, we must rejoice in the immense progress already made and still more in the anticipation of what must come judging from the possibilities opened up by modern research. There is, however, an advance which we have been witnessing, which must be particularly gratifying to every lover of progress. It is not a discovery, or an invention, or an achievement in any particular direction. It is an advance in all directions of scientific thought and experiment. I mean the generalization of the natural forces and phenomena, the looming up of a certain broad idea on the scientific horizon. It is this idea, which had, however, long ago taken possession of the most advanced minds, to which I desire to call your attention, and which I intend to illustrate, in a general way, in these experiments, as the first step in answering the question "What is light?" and to realize the modern meaning of this word.

(To be continued.)

Hull Corporation Supply.

The Frontispiece which represents the engine and dynamo room of the Hull Corporation Supply, recently described in the *Electrical Review*, London, is 48 feet long and 32 feet wide and contains four combinations of Willans engines and Siemens dynamos. Two of these give 150 volts at 300 amperes each, and the other two 115 volts at 1,000 amperes, and foundations have been laid for the addition of two more installations of the latter units. The entire room is spanned by a traveling crane to facilitate the setting up of the machinery.

The station is supplied with a battery house, situated over the boiler room, with two batteries of 120 31 plate cells. Each battery is capable of discharging 250 amperes in case of emergency, although their best working discharge is about 100 amperes. It is said that during the first three years of working the annual depreciation on this type of accumulators has been found in practice not to exceed two per cent.

The Electric Light at Munich.

The Communal Government of the City of Munich have resolved to introduce the electric light for the principal streets, and for this purpose about 300 arc lamps of various powers are being erected. As well as these there will be the electric lighting of the Town Hall which will take 1,800 glow lamps of 16 C. P. Water power is to be used. This installation is stated to be the first in Germany in which the lighting will not be confined to a few streets, but will extend over a much larger area. It is expected that soon the installation will be extended to double its present dimensions. The work is to be in operation by October. Messrs. Schuckert & Company, the well known firm of Nuremberg, are the contractors.

Electric Heating.

BY CARL K. MAC FADDEN.*

The fact that an electric current when passing through a resisting conductor will generate heat has been known for years. During the past thirty years it has been applied to an ever increasing extent in the manufacture of heating devices used in almost an unlimited number of ways. It remained, however, for the electric street railway to open up the field for heating. The fact that there has been issued during the past two years and a half over eighty per cent. of the total number of patents on heating devices shows conclusively that the influences which have made themselves felt during the past few years in the general development of electrical apparatus has not left heating behind in the list of improvement.

The first patents issued on electric heaters were taken out in the fifties, and a few years later several were taken out on an oil well heater for melting paraffine and other obstructing material from the bore of oil wells. It appears that, after oil has been flowing from a well for some time, a large accumulation forms at the bottom which, unless removed, will lessen or completely cut off the supply. Nitro-glycerine was the agent usually employed to loosen up these deposits, but it would seem that an electric heating device in the form of a pointed elongated cylinder would melt out the obstruction, and that this method was used to some extent in the oil regions of Pennsylvania. Patents taken out between 1860 and 1870 show that the idea of placing an electrical conductor in contact with an insulated heat conductor having a relatively larger radiating surface than the electric conductor had been thought of and applied in a number of ways. In the patent specifications filed between these dates platinum is spoken of as a conductor; it evidently being thought necessary to raise the wire to quite a high temperature, therefore platinum was chosen on account of its high melting point.

There are to-day in the neighborhood of 150 patents on electric heaters, which alone goes to show that considerable attention has been paid them by the inventors. A very large number of these patents apply to the heating of cars. One of the earliest applications for patents on electric heating apparatus, filed in 1869 by Burton, specifies that one of the largest applications of this particular heater for which patent is applied is that of "heating railway carriages by means of heated metallic plates placed under the feet of passengers."

There are a great many inventions, however, that are extremely practical, and as this branch of work progresses will, no doubt, be brought out and become marketable articles.

To one who has not investigated the remarkable differences in the carrying capacity of a wire when provided with various means of radiating its heat, it will appear astonishing to see a wire carrying safely several times the current that would fuse it in open air. The principle of all well known heaters is that of placing a good heat conductor, having a large radiating surface, in intimate contact with the electric heating conductor; and there is little doubt that, inasmuch as nearly all serviceable heaters depend upon this principle, the advantages of one make over another will be more in the line of mechanical details of construction than in efficiency. If the heater is made unusually heavy and contains a large amount of heat-conducting material, it will reach its final maximum temperature much slower than one that is built with its heat conductor or reservoir of lighter and thinner material. It may appear immediately after starting both heaters that the latter is not efficient, but if the amount of energy taken up and the radiating surface is the same in both, it will be found that although the heavier heater heats much more slowly than the lighter one, it will hold its heat and remain in a highly heated condition for a longer time after the current is turned off than the lighter heater.

---

* Read before the Chicago Electric Club.

As before mentioned, the electric railway opened up the field for electric heating. The first Sprague road in Richmond, Virginia, was equipped with electric heaters. It has been shown many times that the cost of operating electric heaters on electric roads stands on a par with coal when consideration is made for the value of space that the coal stove generally takes. The electric heaters are generally placed in four or more places in the car where they will be out of the way of passengers when seated, and in such a position that they will at the same time throw their heat into the body of the car. There has been considerable discussion in regard to the amount of current necessary to keep a car warm in cold weather. Reports from roads operating in Northern Michigan and in other portions of the United States and Canada, where the winters are unusually cold, show that from 1,200 to 1,500 watts is sufficient current to keep the average sixteen foot car warm in all kinds of weather. It will be seen that inasmuch as the heaters require no attention whatever, and are practically a fixture of the car, the cost of maintaining and operating on the average electric road will be simply the cost of current. Coal stoves take from twenty to forty cents per day to operate if the least account is taken of time used to keep them in heating condition. The coal stove also takes up room for one or more passengers while it remains in the car, which, on a road doing a good business, is a very important item. Coal stoves, too, on cold days, when being heated unusually warm, become so hot that it is often impossible to stand immediately in front of the stove without burning the clothing of the person standing near.

The electric heaters, being placed under the seats out of the way, and furnishing a lower temperature, cannot be objected to on this score, and being entirely out of the way of passengers, and taking up no space in the car which can be utilized to bring in dividend, often saves in a day more than the entire cost of the current furnished them for the day's run.

There are many times in spring and fall when the mornings and evenings are cool and the middle of the day warm, when a heated car for a few hours each day would add greatly to the comfort of passengers. With coal stoves this is often impossible, unless the car can be taken out of service long enough to have a fire rebuilt in the stove. The many testimonials received from the officials in charge of some of the largest roads cannot leave one in doubt as to the way the public appreciates this method of heating.

If we assume that the only cost of running electric heaters is that of the extra amount of coal burned at the power house, there is no opportunity for argument as to the cheapest method of heating electric railway cars, even when not taking into consideration the convenience and gain in car space by the use of electric heaters.

The total cost of one net horse power at the engine on a plant with an average output of 500 electrical horse power is about six-tenths of a cent per hour. The cost of an electrical horse power hour will be found in this same plant to be about one cent. It will be seen from these figures that the total cost of operating electric heaters will be in the neighborhood of two cents per hour.

I believe that it is just as fair to both sides of the question to assume that the fireman and engineer will not be called on for near as much additional work to furnish current for electric heaters as the street car conductor and other helpers whose time is wholly or partly taken up in attending to coal stoves. In one road which has come under the notice of the writer, a man is paid $1.50 a day to take care of stoves on fourteen cars. This man has no other work to do, with the exception of oiling a few switches near his work. I understand that the man works twelve hours a day, and that the cars run twenty. We may assume that there is at least from 10 to 15 cents a day spent in labor in tending these stoves, the conductor's time not being included. The cost of coal in such a stove will be in the neighborhood of 20 cents when operating twenty hours a day, with coal at $8 per ton. The stove used is open to the same objections that all coal stoves have on electric cars. I assume that electric heaters on these cars could without doubt lower the cost of heating. Under these conditions, as they now stand on this road, the cost of heating during the past winter was far less than in the preceding winter. In many instances coal has to be carried from the power station, or some other point, to the terminus of the line where the cars lay over before starting on their trips. This hauling should be taken in as an item of expense connected with the use of coal stoves.

Street railway companies seldom take account of the cost of operating the two series of incandescent lamps usually found in lighting street railway cars. This lighting takes at least one-third of the energy which might be used for heating.

In a great many estimates which have been made in regard to the cost of coal stoves on electric roads, items have been left out which, when added to the cost of the coal, will bring the actual cost of heating a car on a cold winter day at about the figures to heat the same car by means of electricity. The average life of a street car stove is about three years, and the repairs on even the best make of stoves will be found to amount to a considerable sum before the stove is ready to be abandoned. It also takes time to put these stoves in position and to remove them at the end of the season. It is a well known fact that there are few cars heated by means of stoves that do not have a layer of dust deposited in the car each time the stove is filled or shaken. A deposit of ashes and coal dust five or six times a day on a finely upholstered car soon starts the foundation for an upholsterer's bill, which, of course, on a road equipped with electric heaters, should be a smaller item of expense than on a stove-heated road.

Much has been said in the past in regard to burnouts and other difficulties which occur in the use of electric street car heaters. I believe, however, that with the experience gained in this line by those who have made this branch of work a specialty the failures from such causes as have made trouble in the past will be practically unheard of in the future.

It is by no means an unheard of thing for a coal stove to set barns or cars on fire; a thing which with a properly installed electric heater would be impossible to occur. When properly installed they cannot possibly injure wood-work in the car by excessive heat. There are few street railway companies using stoves for heating that do not find the cost of extra finishing and painting each year, caused by scorched varnish and wood-work around the stovepipe as it leaves the car, to be such as to make quite an additional item to the maintenance of car bodies.

Where power is cheap and coal is dear, which is a condition often met with in mountainous districts supplied with water power, electricity will necessarily play quite a part in heating.

A Pelton water wheel, when running under a large head of water, such as is met with in the Western mountainous districts, can be harnessed to a little mountain stream and develop enough current to heat and furnish power for a small factory with practically no cost except attendance and depreciation.

Under such conditions as these electricity could be used to great advantage for heating purposes even quite a distance from the generating station. There are other places in the West where power is guaranteed the year round at $10 per horse power from turbines. These figures may, of course, be exceptionally low as compared with water power in the Eastern States, and, at the same time, I might say that there are many places in the West where even $10 per horse power would be considered a high figure, power being obtained the year round at $6 to $9 per horse power, delivered at the turbine. Many mines in the West are equipped with large water powers, and could use electric heating to great advantage in keeping certain exposed portions of the power plant at a comfortable temperature. This branch of work has been taken up to some extent already, and, inasmuch as the mine equipped with water power does not depend on coal for its motive power, any coal used for heating would cost even more in the quantities in which it would be purchased than if it was used by the mine for steam generation. In many mines, too, it is out of the question to put in heating apparatus which gives out any gases which might be injurious to the workmen. In the vast majority of cases it is, of course, impossible for this reason to use a coal stove, and entrances to mines and other exposed places in the mines are not heated because it is considered an impossibility.

Since electric heating has been taken up so successfully on electric roads, the fact also presented itself that there would be a large field in cooking devices to be operated by currents of standard voltages to-day used in lighting. A few electric stove companies have at present good lines of cooking utensils which surely fill every want for reliability, cleanliness and good design. There are many cases, especially in the smaller sized cooking utensils, where electricity can compete with coal.

There are, of course, a vast number of plants throughout the country that will not furnish current at a rate which would allow electric cooking apparatus to be used, provided it was simply a question of coal costing so many cents per hour, and electricity a few cents more. There are advantages in the use of electricity for both heating and cooking which must not be ignored. There are a great many places where electric light costs more than gas, and still it is the modern illuminant. It has advantages which gas has not, and the public is not slow to take advantage of them; and for this reason more than any other there are few towns of any size that do not have their electric lighting plant, even though a gas plant has already been installed.

For the heating of chemicals and other applications where an exact amount of heat is needed, electricity possesses more advantages than any other method of heating, and there is no doubt but that in this particular line it will be used to a large extent. For heating water in drug stores, buffets, etc., electricity also should take quite a part. For heating offices and other small rooms in buildings not equipped with steam, electricity, even at current rates for power service, will be found to be far less expensive than one would at first suppose. An office heater capable of warming a fair sized room will be found to be not only an extremely satisfactory way of heating from a sanitary point of view, but will, of course, be entirely free from all gases or odors which are indispensable with the gas or coal stoves.

In conclusion I would say that the field for electric heating seems to be on the eve of development in a sense that will be a surprise to even those laboring in this branch of work. The general public cannot remain long in ignorance of advantages of this method of heating, and although there will be many places where electric heating is an impossibility from a practical standpoint, there will still remain an immense field in which the electric heater will take a firm and permanent hold.

An Automatic Printing Speed-Counter for Dynamo Shafting.

BY GEORGE S. MOLER.*

The automatic printing speed-counter was designed and constructed by the writer, to supply a need felt of having a continuous record of the speed of the shafting which drives the dynamos and other apparatus being used by students in their laboratory experiments.

During part of the year the shafting of the dynamo laboratory at Cornell University is driven by water power, the wheels being situated at the bottom of a deep gorge, and several hundred feet distant. The power is transmitted by means of a wire cable running over large grooved sheaves, and the gate hoisting apparatus is operated by a wire rope passing around drums. No automatic regulator has yet been successfully applied to these wheels, so we have to rely upon hand regulation. On account of this, considerable variations of speed take place, although a tachometer is watched quite closely by the attendant in charge. The variations make it necessary in performing an experiment to continually take account of speed.

The printer (see Fig 1) is essentially a speed-counter which prints the speed at the end of each minute upon a strip of paper, and does this continuously, requiring very little attention. It was built to give the speed of a shaft which runs at about 140 revolutions per minute, but it has a range of from 30 to 185 per minute.

It is connected to the main shaft of the dynamo laboratory by sprocket-wheels and chains, so that the shaft carrying the worm revolves at exactly the same rate as the main shaft. The type wheel is about eight and one-half inches in diameter, and is made by clamping printers' type between a disk and a ring fastened with screws to one side of it. The disk has a series of small holes drilled in it at equal distances apart, and dowel pins passing through holes drilled in the type hold the latter in place. If any of the type become worn, or accidentally bruised, the ring can easily be removed and new ones can be inserted. The type are spaced so as to correspond with the number of teeth of the large gear-wheel which engages with the worm. The printing is done upon a one-half inch tape of district telegraph paper. A typewriter inking ribbon is employed, and as it is fed along it shifts sidewise back and forth so that the whole width of the ribbon is used. It takes several weeks to go once the length of the ribbon.

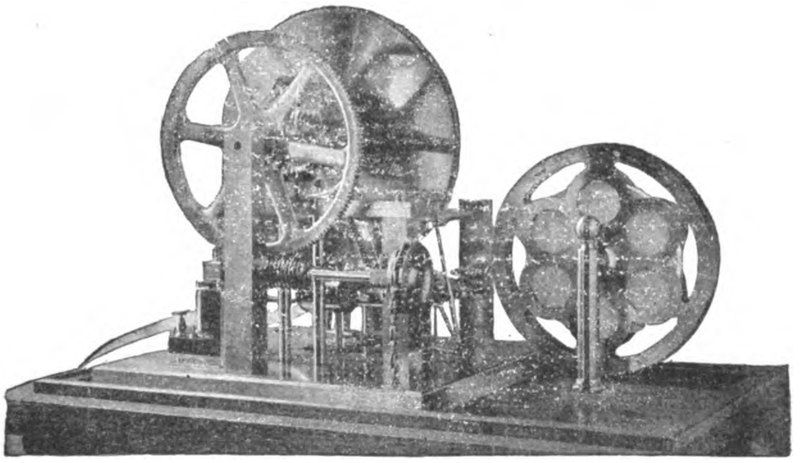


FIG. 1.

The type wheel practically starts from its zero reading at the beginning of each minute. It is necessary to have it do this in order that the number printed at the end of the minute shall be the exact number of revolutions for that minute. When a common speed-counter is used, its index is first set to zero, and it is then applied to the end of the shaft for just one minute, then is withdrawn and read. It is again set to zero, and the operation is repeated, but in doing this a minute or more is lost each time while setting. Now if the speed were not too great, the index wheel might be arranged so that it could be slipped backward or forward the proper amount, after reading, without stopping the counter. In this way a reading made from zero could be taken each minute. A similar method has been adopted in the printer. The type wheel, which is held by friction on the shaft, and is carried with it, is at the beginning of the minute slipped backward or forward until it has the correct relative position, then for the remainder of the minute revolves at the same rate as the large gear wheel on the same shaft. The method of slipping the type wheel around is partly shown in Fig. 2. The toothed wheel *a*, driven by the bevel gear, revolves once for every thirty revolutions of the main shaft. The plate or arm *b* revolves with it when the pawl *c* is allowed to catch in the teeth of the wheel. As the plate *b* goes around with the wheel, the pin *d* overtakes the arm *e*, which is attached to the type wheel, and pushes it along slipping the type wheel on the shaft. When *b* has made one complete revolution, the pin *f* on the pawl *c* comes opposite a notch, not shown in the figure, into which it is pushed by a spring, thus pulling the pawl from the wheel, and also holding *b* stationary. It takes thirty revolutions of the worm to carry the plate *b* around, it coming to rest just at the end of the thirtieth revolution. If at this instant the printing hammer were allowed to act, the number 30 would be printed, but if it does not strike till the end of the minute the type wheel will move with the large gear wheel till that time. The striking of the hammer releases the pin *f*, and the pawl, which has a spring of its own, is again brought in contact with the teeth and so carries the plate *b* around again. If the type wheel should complete its revolution before the pin *d* overtakes the arm *e*, then the arm *e* comes against another pin which stops it, until the pin *d* does overtake it. This is the slipping backward which has been mentioned. If the printer should be driven too fast, so that the type wheel makes a revolution before the minute is up, or if the hammer is not caused to act for several minutes, then it will, the next time it acts, print a zero, which is the type under the hammer while the wheel is held stationary.

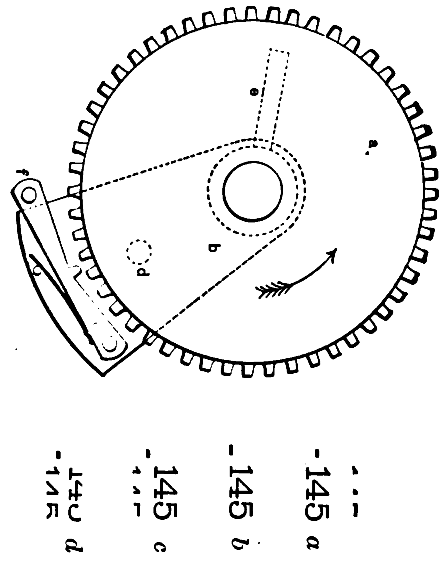

FIG. 2.

The hammer is released at the end of each minute by means of an electro magnet operated by a clock, and when the hammer makes its stroke it opens a switch in the electric circuit while the contact in the clock is still closed, so in this manner the spark on breaking the circuit is made at the switch and not at the clock contact. The hammer is set again by a pin on the side of a wheel coming in contact with a lever, and this closes the switch again before the next contact of the clock. When the machinery is not running, the switch remains open, and so the battery materials are not consumed in useless work.

The numbers move past a stationary point which prints its position upon the paper when the hammer makes its blow. If the number printed is exactly opposite the point, then there has been a whole number of revolutions that minute, but, if the number is above or below it, the fraction indicated by its position can easily be determined. Fig. 3 shows how the fraction of a revolution appears on the record. An exact number, 145 is shown at (*a*), 145.25 at (*b*), 145.5 at (*c*) and 145.75 at (*d*). Usually enough of either the preceding or following number is printed to easily make it out, and to estimate the fraction, which can be read to one-fifth of a revolution. In the original design of this instrument the question of adding a time printing device was considered, for it was thought to be necessary to know just the hour and minute that any part of the record was made. Such an attachment was planned but was not built, for the reason that in nearly all cases the record made will be referred to within the first few minutes after it is printed. If it is desirable to mark a certain point on the record to identify it, the paper can be displaced, and so leave a blank at that point. The paper is fed through at the rate of fifteen and one-fourth inches per hour, and so when necessary this distance can be taken as a unit of length to measure back, and mark off the hours.

One of the ways in which the record obtained is being used is to find the ratio of its reading to that of the speed of the dynamo being experimented upon, then from the record to calculate the speeds for the different parts of the experiment, but this will only answer when the belt is able to drive the machine without slipping.

There is now being built a spindle which is to be tight geared to the main shaft, and which will run ten times faster, or about 1,400 revolutions per minute. This will be for the purpose of testing a student's ability to obtain a correct reading of speed, for the true speed of the spindle will always be ten times the printed speed for that same minute.

The printer which has been described has been running for about three months and has not failed in any respect to do the work that was expected of it.

---

*Read at the Tenth General Meeting of the American Institute of Electrical Engineers, New York, May 17, 1893.

Lecture by Prof. Jas. H. Mason.

A lecture to which is given the caption "Electricity, the Monarch of Wonders," will be delivered by Prof. Jas. H. Mason, at Pilgrim Baptist Church, McDonough street and Patchen avenue, Brooklyn, N. Y., on Wednesday evening, May 31, at 8:15 o'clock. Those who have heretofore listened to Prof. Mason's discourses will be glad of another opportunity to hear him, and all who attend will be sure of instructive entertainment in his pleasing elucidation of what is known of the mysterious agent that he has chosen as the subject of his lecture.

A Modified Deprez-D'Arsonval Galvanometer.

BY LIEUT. CHARLES D. PARKHURST.*

So far as the writer has observed, in all forms of this galvanometer in actual use, or as illustrated and described in various articles descriptive of its construction and use, and in catalogues advertising it for sale, it has always been arranged for use with a lamp stand and scale for reading the deflections by the varying position of the spot of light and image of cross hair reflected from a concave mirror; the protective screen to cut off air currents has always been of glass, and even though a plain mirror be substituted for the concave there is nothing to put the mirror in shadow; hence, as the writer knows from experience, no satisfactory results could be obtained with this form used in connection with a reading telescope.

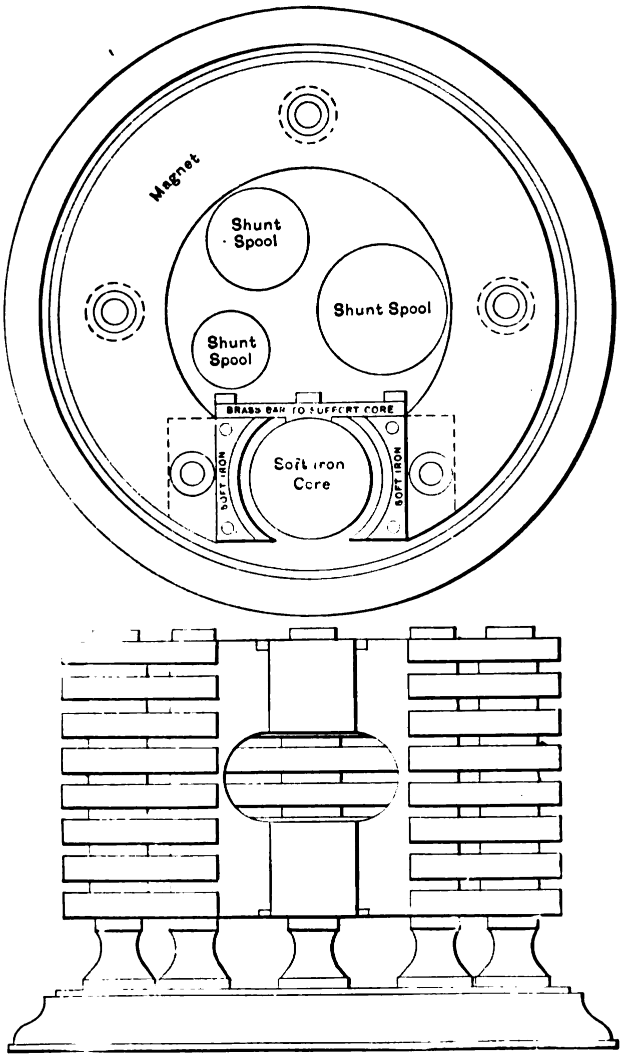

FIG. 2.

Opinions may differ as to the relative merits of the two systems of reading reflecting galvanometer deflections. Certain it is, however, that the lamp stand and scale form a clumsy and bulky outfit. To get a good, sharp and clear image of the spot of light and its cross-hair needs a very strong light or a dark closet in which to use the galvanometer.

In case it is used as a portable instrument, the distance from mirror to scale may not always be kept the same. In this case the constant must be determined for each position of the telescope and scale; but this is very simply done, and need cause no great delay or trouble.

As a specimen of the delicacy of the instrument *as used with a reading telescope*, the writer has frequently seen a deflection, when balancing resistances by the Wheatstone bridge method, *that did not uncover the cross-hair of the eye-piece completely from the zero line of the scale;* the cross-hair is a fine spider web, so fine that it can hardly be seen with the naked eye, and the lines upon the scale are as fine as they can be printed from an engraved plate, vet they did not completely separate from true coincidence; the slight movement of the scale was perceptible, but, of course, could not be measured. This movement indicated that a true balance had not yet been obtained, for finally it would disappear and the mirror hang dead still upon further adjustment of the resistances. This shows how sensitive the instrument is, and *how closely we can see the slightest suspicion of deflection* when using a reading telescope. Resistances adjusted down to absolute zero of the mirror's movement may be taken as pretty closely measured, much closer than is possible with any ordinary galvanometer, and, as the writer believes, much closer than can possibly be done with lamp stand and scale, even with the best of dark closets.

The one great objection to this galvanometer is its want of ready portability; admirably adapted as it is for all kinds of measurements with the utmost delicacy, even in the dynamo room, in proximity to dynamos in action, it yet is not readily transported and set up, owing to the delicacy of the suspension; it will stand a considerable handling without injury, but yet there is much to be desired to render it absolutely portable and free from any liability to injury in transportation, and quickly available, without any tedious adjustment being necessary when set up wherever required.

The Weston voltmeter and ammeter are such an adaptation, these instruments being the simple D'Arsonval galvanometer in another form, and specially constructed and graded for special work; though they are most admirable and accurate, and can be used for all kinds of measurements, they yet leave something to be desired, in that they read by index and not by mirror, and hence extreme refinement of reading becomes impossible. With a view to meet this requirement the following described instrument has been devised and is now in process of construction. (See Figs. 1 to 5, which are drawn to scale, half size.)

The magnet is made circular and compound, with soft iron pole pieces, similar to the arrangement in the Pitkin form of D'Arsonval instrument; but in place of the wire suspension of that instrument, the steel pinion and pivoted centres of the Weston form, with the double hair springs, are adopted.

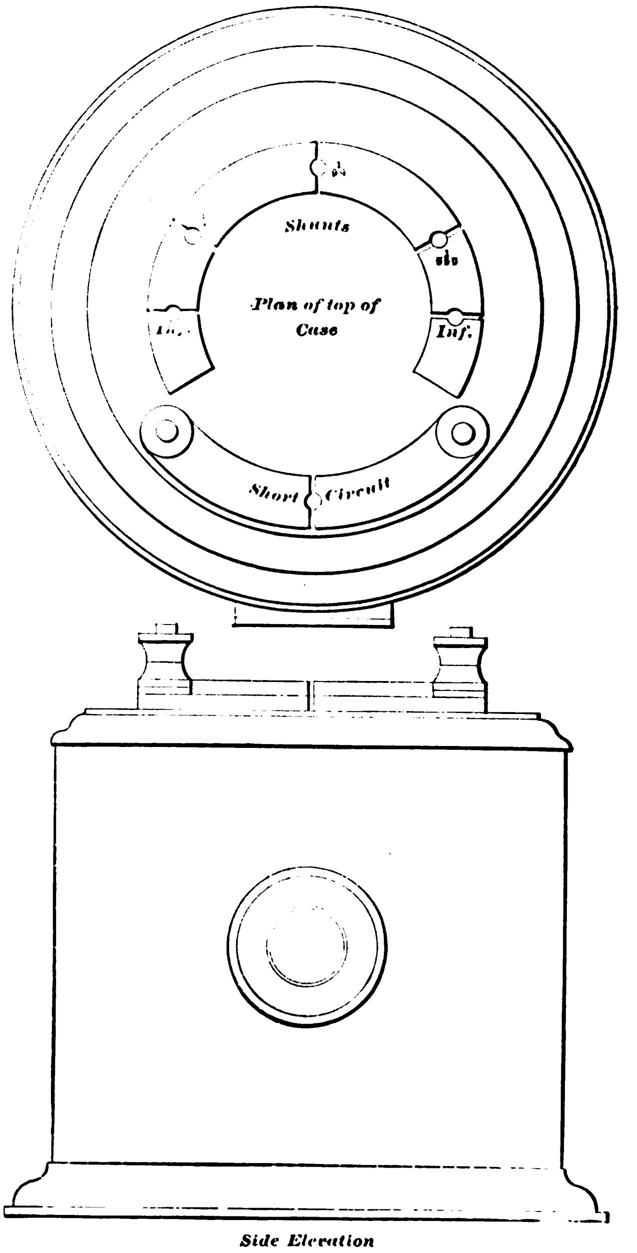

FIG. 1.

The coil may be the flat coil of the Pitkin instrument, or it may be the rectangular coil as generally used. If the flat coil is used the mirror can be attached to the coil; with the rectangular coil the mirror frame is set within the rectangle as shown; in both cases, of course, the mirror turns with the coil. A window, as shown, is provided in the case, to allow the movements of the mirror to be observed. The window can have a brass cap or cover to slip on to protect the glass in transportation.

The bottom and top of the case are of hard rubber; the side of the case is thin brass tubing; in the case, in the space within the bend of the magnet, a set of shunt coils may be inserted, with terminal blocks on the top of the case; the binding posts are upon the top, and a short-circuit may be provided as shown.

---

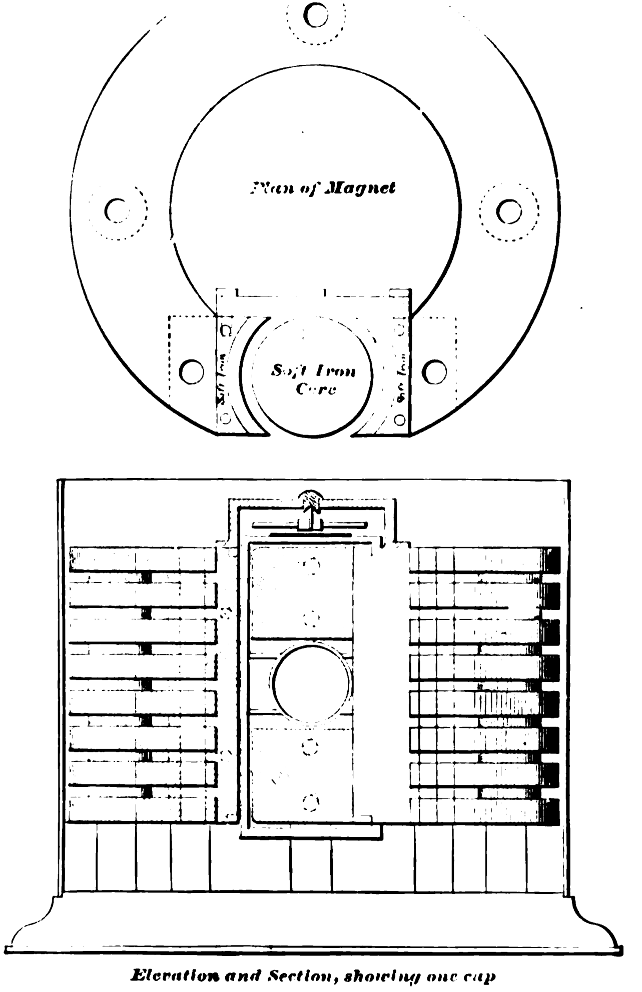
* Abstract of paper read at the Tenth General Meeting of the American Institute of Electrical Engineers, New York, May 17, 1893.

Where the rectangular coil is used, an iron core can be still put in inside the frame of the coil, being cut away as shown to allow the mirror to have room to swing. This really makes this iron core in two pieces, yet it contains a large mass of iron, and helps to strengthen the field of force in which the coil swings; the field of force is kept symmetrical by the shape given to the pole-pieces, so that the lines of force are evenly distributed from front to rear, and the coil remains in practically a constant field during its entire swing. The cutting away of the poles each side of the mirror is to allow the scale to be still reflected from the mirror after large deflection.

We then have a neat, compact and readily portable instrument, whose readings should be as fine and delicate as one may desire. Since the beam of light weighs nothing, and can be made almost as long as one chooses, within reasonable limits, it should be evident how greatly the scale is magnified, and how fine and close the readings may be. The writer may, perhaps, be pardoned if he illustrates this point a little more fully.

Galvanometers with indices must have a very finely graduated scale to read closer than one-fourth of a degree; the average will not read closer than one-half degree; fine readings are, therefore, impossible as a *certainty*, particularly when the tremble and quiver of a finely poised needle and index are considered. The Weston instruments are of this class, and, although they can be closely read *by estimation*, we are *not certain* of the reading, though perhaps we can read close enough for the general work for which they are used.

With a mirror, scale and fine reading telescope we have an index that is imponderable and about as long as we choose within reasonable limits.



Elevation and Section, showing one cap in place, and poles not cut away

FIG. 3.

The scale being graduated to millimetres is easily read at a distance of 3,000 scale divisions, a little over ten feet; the writer has frequently used a telescope at a distance of twelve feet, the distance being only limited by the size of the room, and not by any difficulties in reading the scale.

At this distance, then, a deflection of one millimetre, easily accurately read, means a tangent of $\frac{1}{3000}$ or .000333, corresponding to an angle of about *one minute of arc*, and, as this is the tangent of twice the actual angle of displacement of the mirror, we see that the mirror has actually moved about one-half minute only.

We can read this small angle *positively;* by estimation we can read one-half of a scale division, or our scale can be graduated to half millimetres, and we can read that deflection positively; hence, we see that we can read down much finer, and with more positive exactness, than can be done by any other method, a movement of the mirror being visible in the telescope that could hardly be detected with the unaided eye, and that would be imperceptible if an index had been used.

In conclusion, the writer would say that he hopes the modifications of the instrument as described may be found of value and use. So far as he knows they are original, and are not protected by any patents; any one should be, therefore, free to construct and use such instruments, and if any one so does, and gets as much satisfaction from their use as has been his good fortune, the writer will be fully satisfied.

While upon the subject of measuring instruments, though not exactly pertinent to the instrument described, the writer would beg leave to invite attention to some action being necessary to try and induce instrument makers to be more complete in the data that is furnished with their instruments, which data can only be accurately determined by the maker during process of manufacture, and which, if not then made of permanent record, forever after can only be arrived at approximately by experiment. Such data, carefully and permanently recorded, would oftentimes enhance the value of the instrument more than the extra cost from the extra trouble could possibly amount to.

Reference is here made to the various makers of tangent galvanometers as requiring such attention to the data of their construction, etc., as is shown by the following:

The writer has seen more than one fine standard tangent galvanometer of the Western Union pattern about which there was no information or data to be had as to the *number of turns of wire in each coil* or their mean radii. Similarly, Helmholtz-Gaugain galvanometers have been seen and used by him that were lacking in this same important data. These instruments were all high grade, costing from $125 to $175 each, and yet, for want of data that could have been recorded permanently by the maker at but slight additional expense, they could only be used *positively* and *absolutely* for the *relative* strengths of currents, except by calibrating them absolutely, by reference to some other instrument that had an absolute calibration.

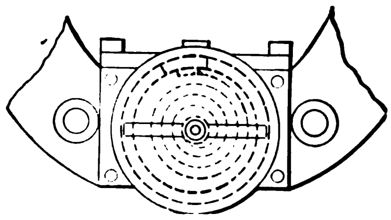


FIG. 4. — PLAN OF CAP CARRYING JEWELED CENTRE.

The formulæ for the use of tangent galvanometers in this manner contain the following quantities as necessary to know:

n = number of turns of wire in coil or coils in use.
r = mean radius in *centimetres* of the coil or coils in use.
d = distance of centre of coil from centre of needle in *centimetres* (for use in sliding coil tangent instruments, such as the Edelman and others).
H = horizontal component of the earth's magnetism at the place of observation (to be determined by experiment and does not necessarily become data for any particular instrument except for a fixed locality).

It will be seen that *the resistance of the coils or of the* instruments is *not* required. Yet we find resistance carefully measured and recorded and much more important data completely omitted.

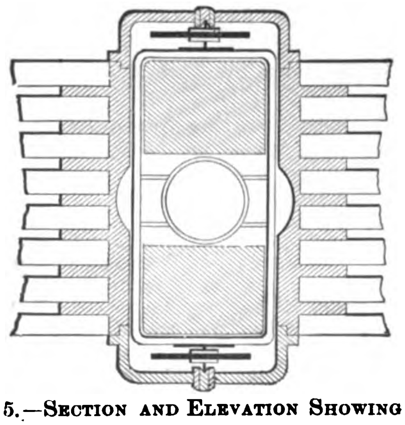

FIG. 5.—SECTION AND ELEVATION SHOWING COIL FRAME, MIRROR AND CAP.

We all know that *if* we know certain quantities, very hard to know or to keep constant, we can find the strength of current giving any deflection by the application of Ohm's law. But, though we may know the exact *external resistance* in circuit by careful measurements, do we know for a dead certainty what the battery or other generator's internal resistance may be from time to time as we use it? Can we be *positively sure* of the E. M. F. of our source of current? Until we can be *certain* of these two changeable and ever changing quantities we cannot be certain of the current strengths as given by Ohm's law, hence the great desirability for use of the general formulæ, into which E. M. F. and battery or other resistance does not enter, and the great need for the furnishing of the proper data by instrument makers to enable us to use these formulæ.

ELECTRICITY.

The Popular Electrical Journal.

Our Platform Is Unchanged. It is proper to recall the announcement made in these columns on August 31, 1892, when the present management secured control of Electricity:

"Electricity, under new ownership, will be conducted as an entirely independent journal, free to give its candid opinion on any and all matters of interest to the electrical fraternity. Our columns will be open at all times to those who have opinions to offer on such matters, whether they agree with us or not.

"We believe that these are the only correct lines upon which a journal, whether electrical or otherwise, can be conducted. We appeal for support to those who believe, as we do, in the fullest possible discussion of all matters of public interest; to those who believe, as we do, that the recent combination of electrical interests is foredoomed to failure in its main objects, and that its success, if possible, would work infinite injury to the development of the electrical industry of America.

"On this platform we stand, with the courage of our convictions, and with no fears as to the result."

There are no amendments, additions or changes in this platform to-day.

We shall continue on these lines until monopoly in the electrical trade has been wiped out never to reappear.

Bluff and bluster will not frighten us nor change our policy. We shall not cease to tell the truth in regard to matters of interest to our readers, and we cannot be intimidated.

As the marble-cutter engraved on the tombstone of the country editor, "We are here to stay."

* * *

Heating by Electricity. The matter of electric heating is at present demanding considerable attention, and was the subject of three papers read before the last meeting of the Chicago Electric Club, one of which we print in abstract in this issue. The problem of electric heating has now been very thoroughly investigated and as far as its practicability is concerned is pretty well established. It can hardly be considered, however, to have been sufficiently developed in point of economy to prove generally useful, although for certain applications it doubtless is now in a position to compete with other methods of heating.

Such cases are of course confined to those in which the heating is required intermittently, and where the consumption of fuel during the periods of disuse is sufficient to more than counterbalance the extra cost of current above fuel.

It is chiefly as a luxury that this method finds its application, and in the line of convenience, electric smoothing irons, cooking utensils, ovens, etc., leaves little to be desired.

It is estimated that electricity at $.015 per horse power per year of 4,000 hours has heating effect equal to coal at $6.00 per ton for house heating, and somewhat less for cooking, which shows that only a small advance in efficiency is necessary to put it in active competition with coal.

* * *

The next dividend on General Electric is due August 1, and nearly $700,000 will be required to pay it.

Have We Libelled General Electric? Most of our readers will have learned, before the current issue of Electricity reaches them, that the publisher of this paper has been indicted for criminal libel on charges preferred by the General Electric Company.

The specific article on which these charges are based is mentioned elsewhere. It is sufficient for the present to state that the article referred to had already appeared in a leading daily paper with over 100,000 circulation a week before we printed it, and that it had not been contradicted by Mr. Coffin or his servants. No changes were made in this office, not even of a punctuation mark.

* * *

No Garbling in This Office. Our friends and constituents may rest assured that Electricity has been guilty of no offence whatever in its treatment of General Electric news. Our "copy" is all preserved carefully, and since the charge of criminal libel was brought against us, we have carefully compared the questions and answers published in our issue of May 17 with the original copy, and we find that our printers and proofreaders have made no error. The matter was copied verbatim from a source which has been recognized as trustworthy.

We are quite ready to believe, in view of Mr. Coffin's present claims, that he never made the statements which we attributed to him. But Electricity has made no mistakes.

* * *

What Are Debentures? We have been frequently asked our opinion of the debenture 5s of the General Electric Company by those who have maintained that the bonds and preferred stock of the company must be worth par whatever the value of the common stock.

From the fact that these debenture 5s have fallen in price from above par to about 84, we suspect that some of the holders have been looking up the exact status of debenture bonds.

Webster defines the word debenture as follows: "A writing acknowledging a debt; a writing or certificate signed by a public officer, as evidence of a debt due to some person; the sum thus due." In other words, debenture bonds are so many notes, and they are not a prior lien on assets.

* * *

A Suggestion. Confidence in the stock and bonds of the General Electric Company may be restored in one way, and in one way only. If the President and Board of Directors are confident that their statements as to the financial soundness of the company are correct, let a committee of the stockholders be appointed, with a reputable chartered accountant as adviser, and make a thorough examination of the company's books, and an appraisement of the various assets. Let them also have free access to the stock-book that they may see what have been the actual transfers of stock since it dropped below 100. It is not many years since this plan was adopted by the Pennsylvania Railroad Company, and with a most wholesome effect. The shares of the company, which had been depressed, were proved conclusively to be worth considerably more than par.

No simpler or more effective plan could be devised.

* * *

Tesla's St. Louis Lecture. We commence in this issue the celebrated lecture delivered before the National Electric Light Association at its St. Louis Convention and a few days before at the Franklin Institute. The present lecture is even more complete than the celebrated London lecture by the same author, and the careful study and wonderful results which have been produced by Mr. Tesla lead to the belief that some practical results will shortly follow in the line of his investigations.

* * *

WE DO not wish to hurt anybody's feelings, but we would like to ask, Why is it that the stock of the United Securities Company was not sold in the present crisis in place of New York and Boston Illuminating Company's stock?. Is it not the only Simon-pure gilt-edged stock in the treasury?

* * *

IF ANY member of the Board of Directors of the General Electric Company can explain why it is that an 8 per cent. common stock is selling at 65, that preferred stock of the same company is below par, and the 7 per cent. bonds are at about 84, we would be pleased to give space to the explanation in our next issue.

* * *

THE General Electric Company have not yet stated whether the stock of the New York Edison Company, recently disposed of, had already been used as collateral for loans. This is an important matter, and the public has a right to know the facts.

* * *

WHATEVER else may be said of Mr. Coffin, no one will deny the accuracy of his knowledge of the affairs of the General Electric Company. It is on account of this accurate knowledge that his appearance on the witness stand, under oath, will be looked forward to with the most intense interest.

* * *

ACCORDING to the *Evening Post*, the cash in the treasury of the General Electric Company was reduced by $1,500,000 in two weeks. Query: If a million and a half will last two weeks, how long will two millions last?

* * *

THE General Electric Company might as well try to dam up the waters of Niagara with stolen blue-prints as to attempt to check, by an action against ELECTRICITY, the anti-trust tide which is sweeping them to destruction.

* * *

IF A man pawns his watch, or his best suit of clothes, the natural inference is that he is in need of funds.

* * *

WHATEVER the weather prophets may say, 'twill be a cold summer for Trusts.

* * *

"There never yet was human power,
That could evade, if unforgiven,
The patient watch and vigil long
Of him who treasures up a wrong."

Criminal Libel Charged.

The General Electric Company Lodges a Complaint Against the Publisher of "Electricity."

The New York Grand Jury, on Thursday last, upon a complaint lodged by C. A. Coffin, President, and S. D. Greene, General Manager, of the General Electric Company, found an indictment for criminal libel against B. E. Greene, publisher of ELECTRICITY. The alleged libellous article was published in our issue of May 17, headed "Mr. Coffin's Admissions."

It is charged that Mr. Coffin's reply to certain questions was not correctly given in ELECTRICITY; that it was maliciously garbled, with intent to injure the General Electric Company.

Our Mr. Greene was in Philadelphia when the indictment was found, and when notified returned at once to the city and surrendered himself, furnishing bail for appearance when the case is called for trial. ELECTRICITY'S case is in the hands of the Hon. Asa W. Tenney, of this city.

Away With All Trusts.

An Anti-Trust Convention to be Held in Chicago.

CHICAGO, May 27.—Gov. Altgeld has received hundreds of responses to his proposal for an anti-trust convention here June 5. The Governors of nearly all the Western States have appointed delegates to be present. The object of this convention is to secure laws to throttle all trusts.

General Electric.

What is Said of It Nowadays.

The General Electric is a striking example. The stock touched 58 in the recent panic, but speedily worked up to 80. The bears sold it all the way up and, although meeting with heavy losses, have so persisted in their attacks that they have been able to recoup. The story is still going the rounds that the dividends will not only have to be reduced, but may be passed altogether, and the company drift into the hands of a receiver. A new story is worked up almost daily, and small holders have become so demoralized that they are influenced by the rumors emanating in the street rather than by the official utterances made concerning the financial status of the company. In view of the fact that the breakdown in General Electric stock and bonds has entailed losses upon holders almost as severe as those caused by the collapse of the National Cordage Company, not a little surprise is manifested at the apparent indifference of those connected with the corporation to the distress occasioned by the shrinkage. Should it transpire, however, that the representations which have been made to various members of the Stock Exchange and to others as to the financial condition of the property for a year past has not been true to the letter there may be a different story to tell. On account of the high standing of these men in the financial community, should any rottenness in the condition of the company be exposed the feeling of indignation would be more intense than on anything that has transpired in Wall Street for the past twenty years. It would probably mark their extinction as factors in the financial world. On this hypothesis alone many holders have kept their shares at an enormous sacrifice, although frequently tempted to sell by the bold assertions of the bears that the concern must end in an administration by a receiver.—*N. Y. World*.

General Electric was the market disturber all day. The unpleasant rumors about the company for several days have made the street very skittish regarding the stock. The sale of valuable treasury stock and the continued talk of a reducton of the dividend were factors against it. In the last hour yesterday, in spite of the better bank statement, the bears made a preconcerted dash against the stock. So successful were they that the price was smashed from 70⅜ to 65, and closed finally at 66⅞. The weakness led to the rumor that the real financial condition of the company had not yet been told, although the management had given the public some very unsavory inside information. When the market closed the general expression was, when, where or how can anybody trust the industrial securities.—*N. Y. Morning Advertiser*.

There is something mysterious in the way this stock has been declining, in the face of the repeated statements that the affairs of the company are in good shape, and that the dividends are not to be cut down. The Board of Directors is composed of some of the largest capitalists in the city, and it might reasonably be supposed that a stock with such strong men behind it would be protected in the market. They seem, however, to be so far behind that they can't catch up to it. To suppose that bear raiding accounts for the decline in the price of the stock from considerably above par to its present price (about 68) is preposterous. There is some good reason for it, and doubtless the reason will become known before a great while.—*N. Y. Times*.

Friends of the company are at a loss to explain this weakness, in view of the assurances of an easy financial condition given by the officers. One explanation was that there was a large loan with a prominent downtown trust company with General Electric as the collateral security. It was the theory that knowledge of this fact having been gained by the bears, a vigorous effort was being made to depress the market value sufficiently to force the closing out of the loan, either voluntarily or from necessity.—*N. Y. Tribune*.

The selling of General Electric was due to the sale of that company's 15,000 shares of Edison Electric Illuminating of New York. Last week the company sold its Edison Illuminating of Boston for $625,000. These sales are to enable the company to meet current liabilities. It is always well to meet current liabilities, but when a company has to sell its assets in order to do it some hypercritical persons are apt to think that it does not speak well for the company's condition. —*Chicago Evening Post*.

The President of the General Electric Company, after a tumble of a dozen points in the stock, was forced to deny a series of rumors designed to produce the impression that his corporation was bankrupt.

Officials of the Whiskey Trust denied that a receivership was imminent.

President Oakes, of the Northern Pacific road, was impelled to deny current rumors that the company would default upon its interest on June 1.—*N. Y. Herald*.

The officers admit that a few weeks ago the company's financial situation was precarious, but affirm that the sale of the Illuminating stock has placed it now beyond the reach of danger. Neither of these assertions will be contested by close observers, and the end of the whole affair is a matter for congratulation. If it should lead to some explanation of what the company really means by "cash" in its published debit and credit statements, shareholders will be still more disposed to stand by their enterprise in the market. —*N. Y. Evening Post*.

There seems to be some return of confidence in General Electric, which has slowly recovered from the panic prices of two weeks ago, and closed yesterday at 79¼. There is still considerable doubt expressed in Wall Street as to the management of this property, and it is still believed that they lack the capital to carry on their business properly. It is largely held by insiders, and this will account for the ease with which it advances.—*N. Y. American*.

For the most part, the property which the holders of the Industrials and other stocks thought they had, has vanished into air. It never existed except in the minds of people. The values were bubbles and the bubbles have been pricked. This is a wiser but a poorer community than it was a few months ago.—*N. Y. Evening Sun*.

Trouble at the General Electric's Lynn Works.

The employees of the General Electric Company are dissatisfied with the 58 hours a week they are now compelled to work, and are agitating for a reduction to 54 hours a week at the old pay. On Saturday the company offered to compromise on 56 hours, but the workmen have yet not taken any decided action as to accepting the proposition.

The Distribution of Power by Alternate-Current Motors—III.

BY ALBION T. SNELL.*

The next point for consideration is the pulsation of the magnetism in the rotary field. This is not a simple matter to represent in a graphic manner, for the magnetic field is not merely the result of the inducing currents in the Drehstrom coils, but it is also largely affected by the frequency and magnitude of the induced currents in the closed coils of the armature, which vary from instant to instant with every fluctuation of load. The frequency of the induced currents will always be less than that of the exciting current—attaining its highest value at full load when the slip of the armature is greatest. It is expressed by $\frac{N - n}{60}$, where N = the number of revolutions of the magnetic field per minute, and n = that of the armature. (If N = 2,400 and n = 1,920, then the frequency will be eight per second.) The average pressure acting in the closed coils will be given by the expression $K\,C\,F\,a\,10^{-8}$,

where K = a constant;
C = the number of turns counted all round the periphery of armature;
F = the average number of lines of force from one pair of poles;
and a = the number of alternations per second of the armature induced currents.

In determining the excitation for multiphase motors and dynamos, it is therefore necessary to make two calculations, one for full and one for light load, just as with direct current machines.

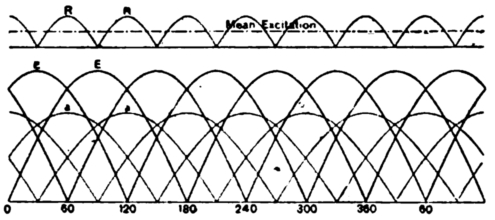

FIG. 10.—Diagram of the Excitation Fluctuations in a Combined Closed Type Drehstrom Circuit.

It is clear that it is not possible to represent the changes of the rotary field magnetism by a general diagram. Fig. 10 shows diagrammatically the relative position of the current and pressure curves in a combined Drehstrom circuit, with the resultant excitation, assuming the armature reactions to have no effect—i. e., the field and armature are supposed to rotate at nearly the same speed. An arbitrary angle of lag of 30 deg. between the pressure and the current in the exciting coils has been assumed, and the curves have been drawn to suit the sine law. The pressure is shown in E_1, E_2, E_3, and the current in a_1, a_2, a_3. The resultant excitation is indicated in curves R, R, R, the limits of which are $2\,a$ and $1.732\,a$, a mean difference of about 7 per cent. If the magnetism varied as the excitation, then the same fluctuation would occur in the rotary field, but owing to hysteresis and eddy currents the mean variation is probably not much more than half as great, say from 4 to 5 per cent.

Now, the torque will vary with the ampere turns, the frequency of the current, and the number of lines of force in the armature; or, the torque $= \frac{C\,i_a\,F\,a}{K_1}$, where i_a = the armature current, and K_1 = a constant, and the other symbols have the same signification as above. The magnetism is determined by the field excitation, and the number of turns of wire is, of course, fixed for a given armature; hence, to increase the torque, it is necessary that the armature rotate more slowly.

The "slip" increases both the frequency and the magnitude of the armature current, thereby weakening the resultant field and lowering the current E. M. F. of the field magnet coils, and allowing more current to flow in the exciting circuit. But since the total magnetism decreases as the armature current increases, there is a point at which the torque is a maximum. This corresponds to a definite current,* which is not at the starting or maximum current, and hence these motors do not exert their greatest effort at starting. In order to avoid large rushes of current when closing the exciting circuit, it is advisable to insert variable resistances in series with the armature windings. This is specially necessary with large machines, and it appears probable from this reason, as well as from other considerations, that large Drehstrom motors will always be designed with stationary armatures and revolving field magnets.

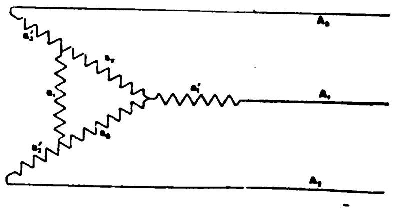

FIG. 11.—Combined Series and Parallel Drehstrom Couplings.

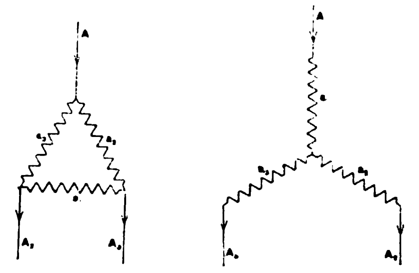
So far, if the difficulty of measuring the power be disregarded, the main point calling for improvement appears to be the magnetic pulsation. The mean variation does not, theoretically, exceed 7 per cent., and, practically, probably not 5 per cent. In order to still further decrease this, Dobrowolski has devised a very pretty combination of the open and closed type windings, which reduces the mean variation of the excitation to 3.5 per cent., when the magnetic field should be practically constant. The winding is shown diagrammatically in Fig. 11, and is known as the double-linked winding. The coils indicated by the symbols $a_1{}^1$, $a_2{}^1$, $a_3{}^1$, are severally wound in two parallel, 15 deg. removed from the closed coils, a_1, a_2, a_3. The complications involved are considerable, and the gain, perhaps, not commensurate with them, yet for large machines the device may prove useful.

There are some important points to be noticed between the series and parallel connections. It has been shown that with the series coupling $e = \frac{E}{1.732}$ (see Fig. 8) and that the currents in the coils and mains are the same, and in the parallel device (see Fig. 5) that each coil carries a current equal to $\frac{A}{1.732}$, and that the pressure at the coil terminals corresponds to the pressure between the mains. These differences are suggested by the term parallel and series, which are in this respect more apt than those of triangle and star.



Practical Application of the Drehstrom

FIG. 12. FIG. 13.

Now, the magnetizing effect exerted by a given number of turns of wire and a definite effective current in the mains will be different with the two kinds of windings.

Consider Figs. 12 and 13, which severally represent the parallel and series couplings, and the direction of current at the instant when the Drehstrom is entering by one main and returning equally by the two others. Let n be the number of turns of wire in one coil. Then the total ampere turns in the parallel device is n A, and in the series arrangement $\frac{3}{2}\,n$ A. Therefore, the magnetizing effect and also the self-induction of the series device is greater than that of the parallel for a given current and a fixed number of turns. Now, the total power absorbed by the two circuits may be made the same by a proper adjustment of pressure and frequency; but since the lag is involved, a complete solution is not very simple. Probably, however, a few experiments made with different sized machines will do more to assist the constructor than pages of mathematical theory.

It must be borne in mind that the triphase system has not been definitely proved to be superior to the diphase, and the leading authorities on the subject differ strongly. Herr Dobrowolski says that "the diphase current now belongs to the past," because in practice machines give curves departing so widely from sine functions. He admits, however, that if the phase difference of current and pressure be the same in each of the two circuits, and follow a sine law, the work is the same in each at the same instant. Messrs. Brown, Kelly, Stanley and Knapp all maintain that there is little to chose between the two systems from this point of view; and Mr. Brown further states that "his extensive experience with multiphase currents shows that two or three phase motors of similar outputs are much the same machines with regard to their respective efficiency, starting torque, weight and apparent watt consumption. This holds good for synchronous as well as non-synchronous machines." It is generally admitted that the Drehstrom presents many difficulties for lighting, and still more for a combination of lighting and power work; but Continental engineers have to a large extent successfully overcome these. Whereas, on the contrary, the diphase system admits of as simple treatment as the single phase one. It appears to be therefore probable that, if multiphase currents come into general use, the diphase may be employed chiefly for combined light and power distribution, and that the Drehstrom may find its field of usefulness in transmission and distribution of power. Experience alone can settle these points.

(To be continued.)

Current Items.

Mr. Swan, the English electrician, declared recently that he had seen electrical blowpipes capable of melting the stoutest iron so rapidly that to melt into a fire and burglar proof safe with this instrument would be the work of only a few minutes, and would be both an easy and noiseless operation. As, however, it would require a forty horse power engine to operate such a scientific tool, banks need be under no apprehension from this mode of attack on their vaults.

Londoners are trying to show that Benjamin Franklin was not the first experimenter in atmospheric electricity, or the inventor of the lightning-rod. It is said that a Catholic priest named Procopius Diwisch as early as June 15, 1754, noticed that lightning was an electric spark and worked out a complete theory of atmospheric electricity. At this time he was living in a small Bohemian village, and he constructed a rod having 324 needle points, connecting the bottom of it to the earth.

---

*Paper read before the Institution of Electrical Engineers, London.

*It is clear that the particular current for maximum torque is dependent mainly on the magnitude of the armature reactions; and if the latter were sufficiently small the greatest torque might be obtained at starting, as is the case with a series-wound direct current machine. With commutatorless Drehstrom motors it is probable, in the author's judgment, that the maximum effort will be obtained with a current little greater than that required for the greatest output.

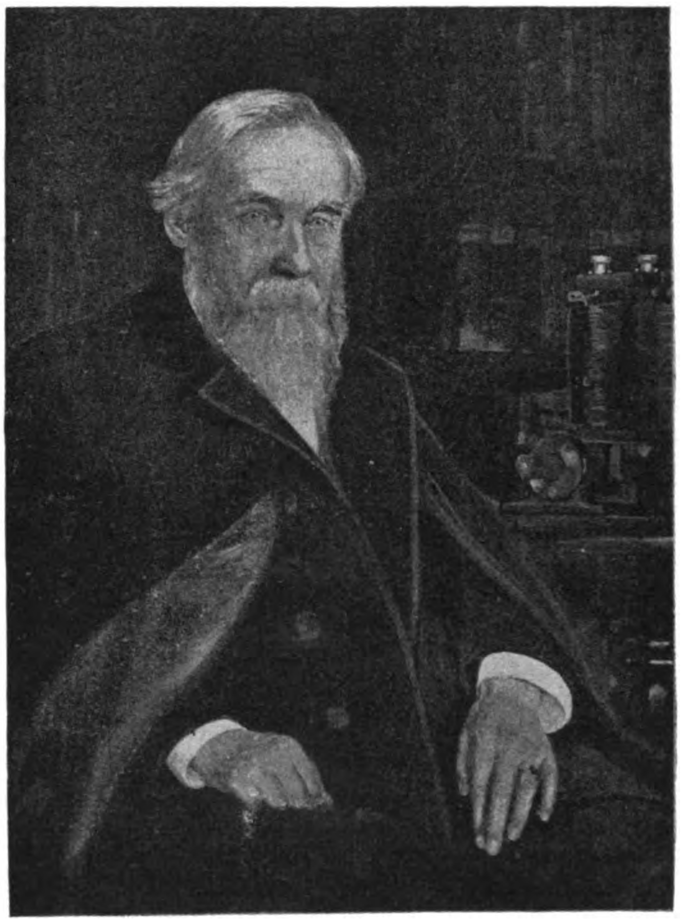
Moses G. Farmer.

Professor Moses G. Farmer died of pneumonia on May 25 at 384 North State street, Chicago. He was seventy-three years old and had been in feeble health for some time.

The body was taken to Boston, where a brief funeral service was held on Monday, the 29th, and the interment was at Eliot, Me., for many years Prof. Farmer's home.

Mr. Farmer was born at Boscawen, N. H., February 9, 1820. His father was a well-to-do farmer and lumber merchant. As soon as the boy was old enough to work he assisted his father in business until the death of the latter in 1836.

Some time after his father's death he went to Andover, Mass., as a student in its well known scholastic institution. This was in the fall of 1837, but he only remained there a short time, entering Dartmouth in 1840, where he made rapid progress. He was unfortunately at this time prostrated with typhoid fever. While at college he was in the habit of giving lessons on the piano and did considerable teaching of music. Singular to state, the typhoid fever left him with but a slight remembrance of one single tune, which marked the end of his musical career.



MOSES G. FARMER.

For a year or so he lived in Portsmouth, N. H., trying to find employment as teacher in a private school. He succeeded, but soon accepted an appointment as teacher in the Academy at Eliot, Me. Just previous to Christmas, 1849, having married, he settled down in Dover, N. H., and continued teaching for a year or two.

Along in 1846, while on his way to Boston, he happened to see a man reading a book entitled "Electro-Magnetic Telegraphy," by Alfred Vail. He was prompted to purchase a copy in Boston, and by the time he reached home he had learned the Morse alphabet. This gave Mr. Farmer a taste for electrical matters, and set him thinking and working on several problems.

Foremost in his mind as he thus plodded on was the subject of utilizing the force he was so fond of experimenting with for propelling vehicles, and so persistently did this idea retain possession of his mind that at last it took actual shape and resulted in the construction of a train of two cars, on one of which was mounted the motor[*] and battery which furnished the current, the other being a passenger car.

Mr. Farmer next identified himself in December of 1847 with Mr. F. O. J. Smith, at South Framingham, Mass., who was then building the telegraph line from New York to Boston. In the following summer he moved to Salem, Mass., and took charge of the line between Boston and Newburyport. Subsequently he undertook to open up offices along the route of this telegraph system and to place the business on a sound working basis.

During his residence in South Framingham he invented an electric striking apparatus for fire-alarm service, two of these machines being built and placed on the Boston Fire Alarm system, one being installed in the Sherman House the other in City Hall. About that time the City of Boston appropriated $10,000 for testing Mr. Farmer's system of fire alarm, which was attracting public attention. Mr. Farmer was requested to make the tests, and soon made several improvements which have been in use ever since. Mr. Farmer was appointed superintendent of the Boston Fire Alarm system, an office he filled until 1853, when he resigned. For a year or two he worked quietly along developing his electrical ideas, but was induced in 1856 to go into partnership with two other gentlemen as electrotypers. Their business prospered until the financial crisis in the following year, when the firm lost most of its capital and gave up. This was a great blow to Mr. Farmer, who, however, kept plodding on until the approach of the war in 1861, when he received an appointment as superintendent of a tobacco-extracting manufactory in Somerville. Here his knowledge of chemistry was found invaluable, and he retained the appointment for quite a long term. In 1872 he was selected to fill the office of electrician at the United States Torpedo Station, Newport, R. I., for six months. So great was the satisfaction his services gave, however, to the Federal Government that the appointment was continued for nine years.

In 1881 his health gave way again, and he became a confirmed invalid. After several years' treatment in New York he moved to Eliot, Me.

In 1852 Mr. Farmer invented, made and used regularly an electric cooking-stove, whereon he broiled his chops and steaks during his residence in Boston, and as early as 1859 he had successfully lighted his house with incandescent lights.

Last year he secured patents for a system of printing telegraphy in England, the United States and other countries.

He was a fellow of the American Academy of Arts and Sciences, fellow of the American Association for the Advancement of Science, member of the Institute of Technology, of the Essex Institute, of the American Society of Mechanical Engineers, of the American Institute of Electrical Engineers and of the English Institute of Electrical Engineers.

Professor Farmer left his New England home last fall, accompanied by his daughter, to spend the winter in Chicago, where it was hoped he might recuperate sufficiently to be able to make a careful study of the electrical exhibits at the Fair. He had arranged for an exhibit of many of his early inventions which will be of great interest.

Mr. Farmer's early work has not been properly estimated. Comparatively few of his inventions and experiments were made public, and the rest were known to a limited circle of friends only. His love for science, as science, was intense, and his work was rarely taken up with a view to pecuniary profit. He led the way by thirty years in many applications of the electric current, and whenever he had arrived at results which settled in his mind the laws of its action, instead of laboring to perfect a marketable invention, would lay aside what he had done and proceed in the search after the unknown.

To those who knew Mr. Farmer best, however the chief interest in his life was not so much because of what he did as of what he was. A more thorough personification of the Christian gentleman could not be found.

Mr. Farmer's wife died some months ago, the only member of his immediate family still living being his daughter, Miss Sarah Jane Farmer, who had been for years his constant companion.

A New Trolley.

A contributor to the Baltimore *American* says: The greatest trouble usually found in the working of the electric trolley on car roads is the wearing out of the bushing in the wheels at such a rate that a rebushing has to be made once a month, and the necessity of excessive daily attention and much oiling is entailed. An attempt has been made to remedy this fault by designing a trolley the bearings of which are made of fiber graphite, and which hence requires no oil whatever. The bearings are fastened on each side of the yoke, and the pin or shaft is fastened to the wheel, both revolving on the bearings in the yoke. This makes the trolley mechanically correct, and avoids all wobbling of the wheel, which is compelled to remain steady and true. Another advantage is that the springs are unable to get out of place, and must constantly keep up the same contact so there is no breaking or arcing of the current, and, moreover, no rattle. Instead of the usual accumulation of oil, grease and dirt on the top of the car, caused by the oil splashing down from the trolley, the car and rope are clean. This trolley wheel is said to have run 900 miles without showing appreciable wear.

---

[*] For detailed description see ELECTRICITY, Vol. III, No. 23.

The National Electric Manufacturing Company.

The Plant to be Operated without Interruption.

The following is an official statement in regard to the receivership of the National Electric Manufacturing Company:

The matter had been under consideration for some time. An action had been brought by Jas. T. Barber et al. against the National Electric Manufacturing Company, the complaint in which sets forth that the company was embarrassed by very pressing claims on the part of creditors which it was unable to pay; that the large plant and valuable business of the company could best be preserved in their entirety for the benefit of all concerned by the appointment of a receiver, etc., etc.

Defendant requested the appointment of Ralph E. Rust as receiver, bond being offered in the sum of $50,000 with William A. Rust, John S. Owen, Jas. T. Barber and Fitch Gilbert as sureties. The same being properly filed, Judge Railey made an order appointing Mr. Rust receiver.

Although the company by reason of the general financial stringency has been considerably embarrassed, the conditions are such that under the receiver the business can and will be carried on without any interruption whatever. There will be no stoppage and a reorganization will probably be effected within a very few days.

The company's plant is worth $300,000; there is a large amount of valuable manufacturing products on hand, and there are also large outstanding orders.

The assets foot up between $500,000 and $600,000; the liabilities are about $300,000.

The placing of the plant and affairs of the company in the hands of a receiver is regarded as the very best possible solution of the difficulties which have been encountered.

Private advices from Eau Claire are to the effect that the company's troubles have been internal rather than external, and that a thorough reorganization will place them in a better position than ever. This can readily be believed, as it is known that the company's apparatus was good, and that it has done a large business.

Electric Lighting Station Opened at Leeds.

On the 10th of May was opened at Leeds (Eng.), by the Mayor of that town, in the presence of a number of influential ladies and gentlemen, the central station which had been erected by the Yorkshire House-to-House Company, the company formed to supply Leeds with the electric light. The station buildings were commenced in the middle of August last year, and were proceeded with as rapidly as circumstances would permit, which was not very speedily. The whole of the machinery was ready for testing on the 10th of April this year. The plant erected consists of three Lancashire boilers 30 feet long and 8 feet diameter. The feed-water is drawn from the condenser overflow pipe, and pumped by means of a duplex pump through filters into an overhead tank holding about 10,000 gallons. The water is thence taken to a smaller tank fixed with boiler feed pumps. The engines are of the coupled compound horizontal condensing type; two of them drive alternators of 100 kilowatts, and one drives an alternator of 50 kilowatts. The two large engines have 14 and 25 inch cylinders, with a stroke of 30 inches. Of the alternators two are capable of giving an output of 100 units each, and the other one 50 units, at an electrical pressure of 2,000 volts. The system known as the "Lowrie-Hall" has been adopted, and during the official tests it is said that an efficiency of 90 per cent. was attained. The farthest distance from the works at which current can be supplied is 2½ miles. We understand that the engines and alternators were tested for a twelve hours' run with a full load before the company took them over. Not the slightest hitch occurred in the carrying out of these tests. The company, when their station is in full working order, will have a supply capacity of about 16,000 lamps, and the inhabitants of Leeds have already made application for 11,000 or 12,000 of these. The firm of Messrs. John Fowler & Company of Leeds supplied the engines.

International Electric Congress.

Preliminary Programme.

Opening Session of the General Congress, Monday, August 21, 3 o'clock P. M.

ORDER OF BUSINESS.

1. The Congress will be called to order by the Chairman of the Local Committee, Dr. Elisha Gray, Highland Park, Ill.
2. Election of temporary Chairman and Secretary.
3. Appointment of a committee to nominate permanent officers. The officers will consist of a President, a Vice-President for each nation sending delegates to the Chamber, a Secretary.
4. Report of this committee.
5. Short addresses by the President and by a few of the Vice-Presidents.
6. Announcements and adjournment.

At the close of this meeting the Chamber of Delegates will assemble for preliminary organization, which will proceed as follows:

1. The Chamber will be called to order by one of the delegates representing the United States.
2. Election of a temporary Secretary.
3. Appointment of a Committee of Five on Credentials.
4. Fixing a time for regular sessions. Adjournment.

At the next meeting of the Chamber the Committee on Credentials will report, and a permanent organization will be completed.

DIVISION INTO SECTIONS.

The General Congress will be divided into three sections, as follows:

A—The Section of Pure Theory, including electric waves, theories of electrolysis, electric conduction, magnetism, etc.

B—The Section of Theory and Practice, including studies of dynamos, motors, storage batteries. measuring instruments, materials for standards, etc.

C—The Section of Pure Practice, including telegraphy and telephony, electric signaling, electric traction, transmission of power, systems of illumination, etc.

These sections will meet for organization and work at 10 A. M. August 22.

Their organization will consist of the election of a Chairman, a Vice-Chairman, a Secretary and a Sectional Committee of three in addition to the officers named above. Temporary presiding officers will be as follows:

Section A—Prof. H. A. Rowland.
" B—Prof. Charles R. Cross.
" C—Prof. A. Graham Bell.

Sections will meet at 10 o'clock A. M. on Tuesday, Wednesday, Thursday and Friday, continuing in session at will, except on Friday, when they will finally adjourn as sections not later than 1 o'clock P. M.

Each section will have authority to divide into sub-sections if it is thought to be desirable.

Papers are solicited upon the following subjects, or upon other topics which may be considered suitable in character.

They should be sent to the Chairman of the Programme Committee, not later than August 1, 1893. Such as are accepted by that committee will be put upon the programme of the Congress, to be presented in full or by abstract according to the time available:

Magnetic units and modes of embodying them in concrete standards.

Methods of avoiding electrical interference and risks to person and property.

National and municipal testing laboratories.

Materials for standards of electrical resistance.

Points of difference of the electrical vocabulary used in different countries.

The direct conversion of the energy of fuel into electric energy.

Comparison of the various methods employed for the electric transmission of power.

The cost of insulation in relation to high pressure for the electric transmission of power.

Comparison of the economies of the various systems of electric distribution.

Alternate current motors.

The behavior of transformers when supplying power to alternate current motors.

The construction of condensers for alternate current purposes.

The measurement of power for polyphase currents.

Direct coupled and non-direct coupled dynamos.

The use of equalizing dynamos in a three and a five wire system.

The use of accumulators in central stations.

The proportions between output of dynamos and the weight of copper and iron employed in their construction.

Electric traction.

Application of electric power in mining.

The adoption of a uniform method of distinguishing positive and negative mains.

Electric supply meters, American, British, Continental.

Criterion of sensibility of galvanometers.

Commercial instruments for measurement of electric quantities.

The relation between the voltage of the arc and the quality and composition of the carbons.

The aging of glow lamps.

The electric working of metals.

The use of electric and magnetic tests for ascertaining the mechanical properties of metals and alloys.

The best material and mode of erection of lightning conductors in the light of recent researches in electric discharges.

The prospecting for iron by magnetic surveys.

International telegraphy.

Fast speed and long distance telegraphy.

The use of batteries or other generators for telegraphy.

Telegraphic lines—land and sea.

Harmonic telegraphy.

Writing telegraphs.

Long distance telephony.

The possibility of providing telephonic communication without wires.

Application of electric signaling to the working of railways (alarms, time, etc.,) and to naval and military purposes.

Magnetic separators.

The use of electricity in engraving and in art reproductions.

The time allotted to the discussion of the papers presented will be determined by the several sectional committees. In the discussion of papers the Chairman of the section will name the first speaker.

THE CHAMBER OF DELEGATES.

The following topics will be considered by the Chamber of Delegates:

Adoption of definitions and values of fundamental units of resistance, current and electromotive force.

Adoption of definitions and values of magnetic units.

Adoption of definition and value of the unit of self-induction.

Definitions and values of light, energy and other units.

The standardization of electric lights.

The consideration of an international system of notation and conventional symbols and of a more uniform and accurate use of terms and phrases in electrical literature.

A commercial standard of copper resistance.

Together with such other topics as may properly come before this body.

The hours of meeting for the Chamber of Delegates shall be determined, after the first session, by the Chamber itself; and it shall also decide upon the admission of persons not delegates to its sittings.

It shall finally adjourn not later than 1 o'clock P. M. on Friday, August 25, and at the last meeting of the General Congress the officers of the Chamber shall report to it a summary of its proceedings and the conclusions reached.

Public lectures of a popular character will be delivered by eminent electricians at 8 o'clock P. M. on Tuesday, Thursday and Friday of the Congress week.

The General Congress will assemble to hear reports and for final adjournment at 3 o'clock P. M. Friday, August 25.

Prof. T. C. Mendenhall, Washington, D. C., Chairman.
Carl Hering, Philadelphia, Pa.
Prof. W. A. Anthony, Manchester, Conn.
Prof. H. A. Rowland, Baltimore, Md.
A. E. Kennelly, Orange, N. J.
Prof. F. B. Crocker, New York City.
Prof. E. L. Nichols, Ithaca, N. Y.
Prof. H. S. Carhart, Ann Arbor, Mich.
Committee on Programme.

American Institute of Electrical Engineers.

At the regular monthly meeting of Council, held May 16, the following Associate Members were elected: Fred. Fiske Barbour, 15 First street, San Francisco, Cal.; A. Barth-Bartoshevitch, 160 Arch street, Allegheny City, Pa.; Waldo C. Bryant, Bridgeport, Conn.; James Burke, 24 Front street, Schenectady, N. Y.; John Alfred Cabot, 123 Garfield Place, Cincinnati, Ohio; Adolph Frederick Christmas, Johnstown, Pa.; J. Hally Craig, John Hancock Building, Boston, Mass.; Ignacio Manuel da Cunha, Emprera Industrial Gram-Para, Para, United States of Brazil; Thomas B. Doolittle, 125 Milk street, Boston, Mass.; Henry W. Frye, *Times* Building, New York City; Clarence E. Gifford, 860 Prospect avenue, Buffalo, N. Y.; George Heli Guy, 131 West 34th street, New York City; Charles A. Lieb, 44 Broad street, New York City; James Grieve Lorrain, Norfolk House, Norfolk street, London, W. C., England; Charles P. Matthews, 15 Heustis street, Ithaca, N. Y.; Theodor J. W. Olan, New York City; Walter M. Petty, Rutherford, N. J., and New York City; Fred Sheffler, 74 Cortlandt street, New York City; George C. Sonn, 285 Bellevue avenue, Newark, N.J.; Alfred E. Weiner, 24 Yates street, Schenectady, N. Y.; Peter Wright, Drexel Building, Philadelphia, Pa.; V. H. Yarnall, 29 Broadway, New York City.

Legal Notes.

The Franklin Electric Light Company, of Cape May, has paid its creditors in full, and proceedings in the Court of Chancery asking for a receiver have been discontinued.

A case has been before the courts in San Antonio, Texas, which is the result of a wrangle between the West End Street Railway Company of San Antonio and the Thomson-Houston Electric Company as to the value of a plant erected by the latter company for the former. The defendants claim that the Thomson-Houston Company had agreed to put up a first-class electric street railway plant for them for a stipulated amount of money. The street car company paid $15,000 on the contract. It claims that before the remaining note, amounting with interest to $10,000, fell due serious defects were found in the plant, whereupon the defendants resisted payment of the note.

Judgment has been entered against the Chatham Electric Light Company, of Chatham N. Y., for $11,732 in favor of the General Electric Company for electrical machinery and wares sold in 1890, 1891 and 1892 by the Thomson-Houston Electric Company.

The Covington Electric Light Company field suit in the Circuit Court at Newport, Ky., against the Suburban Electric Illuminating, Heating and Power Company and the City of Newport for $16,562.72, with interest from May 1, 1898, till paid for and its costs. The city of Newport is made a co-defendant in the case for the reason that it is indebted to the Newport Electric Light Company in the sum of about $20,000 for electric light furnished by the latter.

A legal fight between the Winnipeg Street Railway Company and the Electric Railway Company, at Winnipeg, Manitoba, has been going on for some time. The former company, which has been established for the last ten years, claims to have been given the exclusive rights to the streets by the city council. The case first came before the Court of Queen's Bench, whose decision was favorable to the Electric Company. An appeal was taken to the Supreme Court of Manitoba, the judges of which have unanimously ruled that the city council has no power to grant a monopoly of the streets, and that the new company could not be interfered with.

The St. Joseph, Mo., *News* gives the following particulars regarding the sale of the property of the People's Street Railway, Electric Light and Power Company, comprising all the street railways of St. Joseph. It says that M. M. Crandall, master in chancery of the company's property, which was sold at auction recently for $565,000, will "make his report of the sale to Judge Ramey, in Division No. 2 of the Circuit Court, next week, and when the sale is confirmed by the court the property will pass into the hands of the purchaser, James T. Gardiner, chairman of the reorganization committee of the bondholders. The price paid being $235,000 less than the amount of the mortgages held by Harriman & Company, of New York, naturally, while the debt is released, there will be nothing left for the small stockholders. When the settlement by the master in chancery is made the property will pass into the hands of the reorganization of the old company, viz., the St. Joseph Traction and Lighting Company, whose intention is to spend several thousands of dollars in improving and adding to the rolling stock of the various lines and in replacing the old track with new rails."

Boston Notes.

Contracts have been signed for the construction of an electric road at Bath, Me., and work will commence at once. The road is to be in operation by August.

The movement in favor of municipal ownership of electric lighting plants has extended to Cambridge, Mass, and action is being taken thereupon. On Thursday evening a special committee of the City Government held its first meeting to consider the subject. The president of the Cambridge Electric Light Company appeared to show that the city would not save any money. He estimated that his company earned net for the past year about $20,000.

A new submarine cable is to be laid at once between the Isles of Shoals and the New Hampshire mainland. The cable will be $7\frac{3}{4}$ miles long and is to cost $5,000. A shorter cable is to connect Star and Appledore islands. These islands are very popular health resorts.

An interesting evening was spent last Monday by the members of the Eliot Club, Jamaica Plain, a fashionable suburb of Boston, on the occasion of an address entitled "The Invention of the Telephone and the Development of its Use," which was given by Mr. J. H. Farnham, electrician of the New England Telephone and Telegraph Company. During the address many interesting drawings of the earliest forms of telephone instruments were shown and some remarkable experiments to show the wonderful sensitiveness of the telephone were made. There were about 150 ladies and gentlemen present, all of whom were delighted with all they saw and heard. Through the kindness of General Sherwin, president of the Telephone Company, some twenty telephones were placed about the room and connected with the long distance telephone line to Springfield and Chicago. For the entertainment of the audience vocal and instrumental selections were rendered in the operating room at Chicago, every note of which was distinctly heard by all present. A good deal of amusing conversation was also carried on over the line between Chicago, Springfield and the Eliot Hall, Jamaica Plain, where the meeting was held.

A lively meeting took place at Blackstone, Mass., last Monday, on the occasion of a public hearing granted by the Selectmen on a petition presented by the Woonsocket Street Railway Company for leave to erect poles and maintain wires and have an exclusive franchise to Blackstone's streets for twenty-five years. Mr. J. M. Klingelsmith of Chelsea, formerly identified with the General Electric Company, controls the company, and he and those interested with him didn't get any satisfaction from the selectmen. For two hours there was a hot discussion but no definite result was reached. It was contended that hitherto the Woonsocket Company had not lived up to its promises in taking care of the streets, which was part of its original contract. The feeling was against granting a twenty-five year franchise for a trolley road, seeing the possibility of such a system being altogether superseded within the next few years.

In accordance with a decision arrived at a few days previously, 34 out of a possible 40 members of the Massachusetts Senate made a trip to Milford and Hopedale last Tuesday to secure practical experience of the working of storage battery cars before deciding the fate of a bill for granting the Storage Battery Railway Company of Cambridge authority to run its cars over the West End tracks in that city. The visiting Senators rode over the entire system between Milford and Hopedale, witnessed many trying tests, and expressed themselves satisfied when the cars ran over 10 per cent. grades without the slightest difficulty. Senator E. P. Shaw, who is a bitter opponent of the storage battery project, had with him an expert from the General Electric Company to criticise and find fault with everything pertaining to storage battery propulsion, and this he did so persistently that his presence became actually annoying, and he had to be requested to give the Senators a chance of judging for themselves. Some of them admitted their conversion to storage battery propulsion in preference to the overhead trolley. The bill had passed the House almost unanimously, but when brought up in the Senate Wednesday it was thrown out, to the astonishment of everyone but the Senators themselves, by a majority of 30 to 5. This defeat, however, is likely to be only temporary, as the promoters, backed by a growing public opinion, are determined to push their undertaking to a successful issue.

On the Stock Exchange, this city, General Electric Stock went off several points Thursday when the statement got known that the Trust had disposed of $1,500,000 of gilt edge securities for Europe. The selling of its treasury holdings of stock in the Edison Illuminating Company, New York, as above, set the men on the street wondering what would be the next move to raise cash. The transaction had an ominous look to many.

The Long Distance Telephone Company has just declared a quarterly dividend of $1\frac{1}{4}$ per cent. which is equivalent to 5 per cent. per annum. The stock in this company is issued by the Bell Telephone Company.

The new electric railway between Waltham and Watertown, Mass., was opened for traffic last Sunday. The road is a success.

Chicago Notes.

The death of Moses Gerrish Farmer in this city, last week, was sad news to the electrical fraternity at large, and especially to his numerous friends who have made his acquaintance since he has taken up his residence in Chicago. No services were held in this city, but the body was sent directly to Boston last Saturday, where the funeral rites will be held.

The Calumet Electric Railway Company, which operates a number of cross town lines on the south side of the city, has just completed arrangements with a number of railroads entering the city to transfer all their World's Fair passengers from the suburban station at which the road crosses the electric line to the Fair grounds. The roads which have entered this agreement include the following: The Rock Island, Marion, Erie, Baltimore and Ohio, Wabash, Pennsylvania and Lake Shore. A number of new cars will be added to accommodate the increased traffic.

D. E. Robison, of Nashville, Tenn., was a visitor in the city last week, and took time to show his new patent trolley wheel to a number of the railway supply houses. Mr. Robison is one of the few colored gentlemen who have entered the electrical field as a means of earning a livelihood. He has several important inventions upon which patents are pending.

The K. A. P. Electrical Novelty Company have established an office at 440 the Monadnock Building, from where they will handle their patent K. A. P. Lamp Socket and other electrical appliances. Wm. D. Kury is in charge of the Chicago office.

The Knapp Electrical Works has entered suit in the Superior Court of Cook County against the National Electric Company to recover $1,981.33 on an attachment.

General News.

What is Going on in the Electrical World.

Omaha, Neb.—The steam motor line to Manawa is to be changed into an electric line immediately.

Rockport, Tex.—The electric light plant belonging to G. S. Barlow was destroyed by fire on the 12th inst.

Oakland, Cal.—The old Meetz horse-car road between Oakland and Alameda has been superseded by the Alameda, Oakland and Piedmont Electric Railway.

Nutley, N. J.—The town committee have selected locations for 100 electric lights to be paid for by the township.

Macon, Ga.—J. L. Camp, J. King and E. T. McGhee have bought a controlling interest in the Electric Light Company.

Savannah, Ga.—The Electric Railway Company has renewed its lease of the Savannah and Isle of Hope road for three years.

Amsterdam, N. Y.—The Amsterdam Street Railroad Company has been granted a franchise and will extend their road to Fort Johnson.

Pasadena, Cal.—The Consolidated Electric Company of Los Angeles will build an electric road to connect Los Angeles with Pasadena.

Salt Lake, Utah.—An extension of the franchise of the Henderson-Brinker Electric Street Railway has been granted by the city council.

Indianapolis, Ind.—Rumors of negotiations between the two rival street railway companies were in circulation last week, but there is nothing in sight to verify them.

Hamburg, N. Y.—The village board has entered into a contract with the Hamburg Water and Electric Light Company to furnish lights for this place for three years.

Johnstown, Pa.—Ex-Governor Beaver and Gen. Hastings are interesting themselves in the proposed electric road to connect Hastings and Spangler, two new coal towns.

Plainfield, N. J.—An electric trolley road is planned to run from Plainfield to Orange along the Watchung Mountain range. The intention is to develop the mountain top for private homes.

Providence, R. I.—The consolidation of the Pawtucket Valley Electric Street Railway Company and the Electric Light Company, whose plant is located at River Point, has been effected.

Syracuse, N. Y.—At a meeting of the men interested in the proposed Syracuse, Fayetteville and Manlius Electric Railway, recently, it was decided to have the routes suggested surveyed at once.

San Antonio, Tex.—The Citizens' Electric Power and Street Railway Company have been empowered by the Mayor, having paid to the city $5,000, to construct an electric line on certain specified streets in this city.

San Jose, Cal.—The common council has at last decided to report in favor of granting a franchise for an electric road to Alum Rock Park, the franchise to be granted to the highest responsible bidder. Bids will be opened June 26.

Youngstown, Ohio.—The *Vindicator* says that word has come from Canfield to the effect that New York capitalists have offered to take the entire amount of stock needed to complete the proposed electric street car line from Canfield to this city.

Wilmerding, Pa.—The announcement that the Westinghouse Electrical and Manufacturing Company intend moving their entire plant to Wilmerding has given a boom to real estate in the neighborhood, McKeesport being among the places benefited.

Eldora, Iowa.—The boiler in the electric light plant exploded on the night of the 18th, demolishing the building and damaging buildings in the neighborhood. A. E. Gier was instantly killed, and Firemen Templeton badly hurt. The loss was over $20,000.

Middletown, Conn.—It is probable that the street car system in this city will be equipped with electricity in a few weeks and also that the lines will be extended to the asylum and then as far as Pameacha bridge in that direction. The trolley system will be used.

Paterson, N. J.—The Paterson Central Electric Company has 38.40 miles of street railway track; capital stock, $140,750; paid up. $94,000; funded debt, $27,000; other debts, $7,000; cost of road, $1,127,549; expenditures for repairs, etc., $217,000; gross receipts, $23,415.

Fort Lee, N. J.—The Electric Construction Company has begun to build the electric railroad which is to extend from the Fort Lee Ferry to the Institute of the Holy Angels. Work has also been begun on the Palisade Railroad. It is to be completed to Fort Lee by November 1.

Charleston, S. C.—The Electric Light Company have been making great improvements in their plant, and have adopted the meter system in supplying their light to customers. It is reported to be more satisfactory all round than the old system of charging by the month.

Hackensack, N. J.—The Bergen Turnpike Company have decided to carry out the project that it was hinted they had in view when the new directory was organized, of building an electric road from Hackensack to connect with lines in Jersey City and Hoboken. The length of the road at the start will be nine miles and it is probable the line will be eventually extended to Saddle River valley.

Bath, Me.—The Electric Railroad Company will begin work at once on its line. The Worcester Construction Company will construct the road bed, the Pierce Construction Company of Boston the overhead work and the Westinghouse Company the electrical equipment. The road is four miles long and extends a couple of miles into the suburbs.

Eau Claire, Wis.—Ralph E. Rust has been appointed receiver of the National Electric Manufacturing Company. The assets appear to be $500,000, and the indebtedness $350,000. The company is one of the largest electrical manufacturing concerns in the United States. The cause of the appointment is threatened suits arising out of the stringency of the money market.

Gettysburg, Pa.—Judge Advocate General Major George B. Davis, U. S. A., who had been officially instructed to inspect the electric railroad that is now being built over the battlefield, for the purpose of ascertaining whether the line would be injurious to the historical value of the field, will, it is understood, advise the War Department to intervene and take the land and stop the further building of the railroad.

Monrovia, Cal.—Monrovia will soon have an electric light plant and will supply the adjoining towns of Sierra Madre, Duarte, Santa Anita and El Monte with light, and have power enough to run a motor railway between Los Angeles, Pasadena and Monrovia. The plant will be run by water power from the Saw Pet canyon just north of Monrovia. Los Angeles and San Francisco capitalists are the projectors of this enterprise.

Windsor Locks, Conn.—A new industry may be established at this place in the shape of the manufacture of a new electric lamp. The lamp is the invention of a Mr. Greene. Parties were in town a few days ago to look at the building owned by the Electric Light Company. The directors of that company are to make arrangements to have the concern locate here. It is expected that about forty hands would be employed at first.

Baltimore, Md.—The new station of the Suburban Railway Company when finished is expected to be capable of generating sufficient electricity to operate every electric road in the city and suburbs. The machinery employed is to have a capacity of 6,000 or 7,000 horse power. The station at Waverly will be kept intact for emergencies. The new station will be ready for operation as soon as all the lines of the City and Suburban Railway Company are prepared for electricity.

Troy, N. Y.—The Troy City Street Railroad Company have applied to the city council for permission to change the motive power of their White Car line from horses to electricity.—Since the project of constructing an electric road from Albany to Sandlake has been made public, some influential Trojans have been considering the feasibility of running a line from Troy to Sandlake, so as to prevent a diversion of the trade now carried on between these two places to Albany, and efforts will be made to carry out the scheme.

Hartford, Conn.—The Electric Street Railway bill, as amended, has finally passed both Houses. There are seventy applications for charters for electric railways affected by the bill. The original section prohibiting the transportation of freight without permission of the railroad commissioners is reconstructed so that every company may transport persons and property, but in freight transportation shall be subject to regulations prescribed by the Superior Court, on application of the railroad or the local authorities. The order may cover the entire line or a part of it. The matter of paralleling any steam or electric street road is left to the decision of the Superior Court instead of the railroad commissioners. The House provision that any joint stock corporation may build an electric street railroad was erased.

New York.—The Union Electric Railway Company has gained possession of the lines of the Westchester Electric Company, which, when completed, will run from the Hudson River to Long Island Sound, through the northern part of the city. The Union will extend its present system from Fordham, meeting and connecting with the new line at Woodlawn. It is stated that the Union has also acquired title to all of the other lines operated in the lower part of Westchester County.—An electric gig for the new cruiser New York is being constructed by the General Electric Launch Company.—A public exhibition was given at 42 Park Place on the 24th inst. of a telephone that, it is claimed, does not in any way infringe upon the Bell patents. Several tests were made, with satisfactory results. The inventors and promoters claim validity for their patents on the ground that no carbon is used for vibratory purposes, and a general simplicity of construction that will admit of a line five miles in length being constructed at a cost for materials, batteries, transmitters and receivers of only $62.40. This includes the purchases of all rights from the owners of the patents.

Paranite Wire.

The Indiana Rubber and Insulated Wire Company of Jonesboro, Ind., has found it necessary to establish an Eastern sales department at 220 Devonshire street, Boston, where all orders for that part of the country will be promptly taken care of. The high quality of these goods and the excellent reputation they enjoy have been still further enhanced by the following strong letter of commendation and data of tests received a few days ago from the Massachusetts Electrical Engineering Company:

BOSTON, Mass.

We are in receipt of your favor of the 3d inst. referring to your Paranite wire, and herewith enclose, as you request, a set of copies of our tests.

As we stated to you verbally, there is no doubt that the Boston Board of Fire Underwriters will accept this wire for this city on the basis of the tests we have made. Our own opinion is based on this same information, but as the tests speak for themselves we think there is nothing further which we could add that would be of any value to you.

Yours very truly,

STONE & WEBSTER.

The above letter was accompanied with the following data of tests made according to the requirements of the Boston Board of Fire Underwriters:

Report of Insulation Resistance.

Test No. 722.
Marks: Paranite cable No. 2,030, No. 14 wire.
Length, 50 feet. Temperature, 55 degs. Fah.

Resistance of Insulation in Megohms.

Time	500 feet.		Per mile.	
On immersion.	Negative.	Positive.	Negative.	Positive.
After 1 day.	26,000	26,000	2,500	2,500
" 2 days.				
" 3 "				
" 4 "				
" 5 "				
" 6 "				
" 7 "				
" 8 "				
" 9 "				
" 10 "				

Remarks.

Three minute electrification, 550 volts. Qualities for withstanding abrasion, good.

Test No. 728.
Marks: Paranite cable No. 2,030, No. 14 wire.
Length, 500 feet. Temperature, 55 degs. Fah.

Line Test.

Time	500 feet.		Per mile.	
On immersion.	Negative.	Positive.	Negative.	Positive.
After 1 day.	26,000	26,000	2,500	2,500
" 2 days.				
" 3 "				

Remarks.

Three minute electrification, 550 volts.

Test No. 723.
Marks: Paranite cable No. 2,173, No. 14 wire—Taped wire.
Length, 490 feet. Temperature, 55 degs. Fah.

Resistance of Insulation in Megohms.

Time	490 feet.		Per mile.	
On immersion.	Negative.	Positive.	Negative.	Positive.
After 1 day.	30,000	30,000	2,800	2,800

" 3 "				
" 4 "				
" 5 "				
" 6 "				
" 7 "				
" 8 "				
" 9 "				
" 10 "				

Remarks.

Three minute electrification, 550 volts.

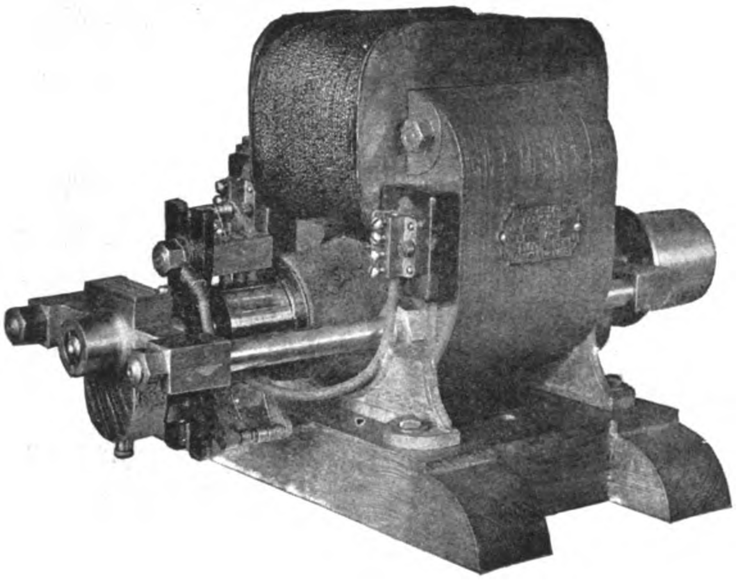
New Perret Motor.

The following illustrations represent a new type of Perret Motor brought out recently by the Elektron Manufacturing Company of Springfield, Mass. As in all motors and dynamos made by this company, the lamination of the field magnet cores is adhered to in these machines. The armature is in all respects the same as that used in the well known Perret machines of the consequent pole type which have gained a wide reputation for efficiency and mechanical excellence in the past four or five years.

The new machines, although much simpler in construction, by reason of having one field coil instead of four, are even more efficient than the consequent pole type. The iron is of the best for the purpose, the magnetic circuit is short, and, by means of a patented method of dovetailing the iron plates, the single joint in the core is most perfectly made.

The bearings are of composition bronze and self-oiling, and for ordinary voltages carbon brushes are used.

This style of machine is made in five sizes, from one-fourth to two horse power, inclusive, and are known as types X and Y. Each motor is accompanied by a neat fire-proof starting box.



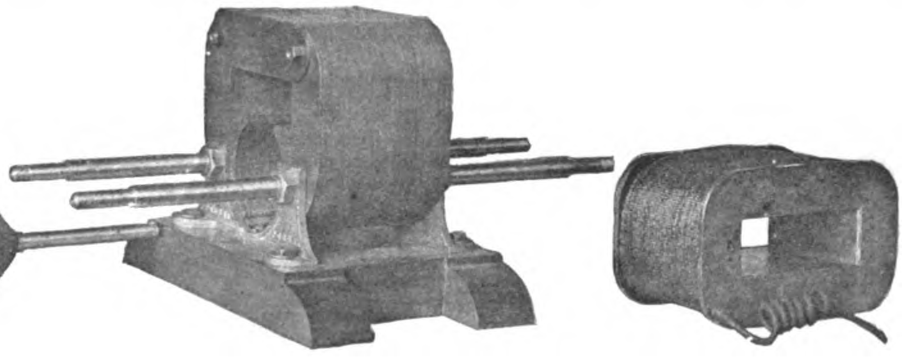
THE PERRET MOTOR.

New La Roche Direct Current Dynamo.

The cut herewith represents the new type of direct current dynamo built by the La Roche Electric Works of Philadelphia. This has been one of the most successful machines that have ever been turned out of their establishment, and for it they have received a number of duplicate orders, giving great satisfaction wherever placed.

The machine, as will be noticed, has a Gramme ring armature of the latest improved construction, thereby reducing the speed very materially. It has all modern improvements, with all parts interchangeable and made to gauge. The machine is compound wound and was designed by Mr. F. A. La Roche. It is so constructed as to stand the most severe abuse that any machine of this kind can be subjected to. It has self-oiling bearings and automatic oil-overflow. The brushholders are of a new design and so made that any degree of tension can be secured, and so arranged that a free movement of the brushes around the commutator is allowed.

The commutator is made of hardened copper well insulated with mica. It will be noticed that the winding of the machine is peculiar, as any of the coils, either series or shunt, can be removed and new ones put in place without interfering with any other part of the machine. An extra heavy steel shaft is used which permits the armature to run very close to the pole pieces, consequently increasing the efficiency of the machine.



THE PERRET MOTOR.

A test of one of these machines showed that there was a variation of only 1 3-10 volts between no load and full load, which is a sufficiently close regulation for any purpose that a machine of this kind may be put to.

Within the last three months this company has installed fifteen of these machines in Philadelphia and vicinity, and they are spoken of in the highest terms.

The La Roche Company are now making arrangements for an increase in their manufacturing facilities.

Pope, Read & Rogers.

In response to the solicitations of many of the clients of the old firm of Pope, Edgecomb & Terry, attorneys and solicitors in electrical patent cases, it gives me pleasure to inform you that I have completed satisfactory arrangements for the resumption of the business so successfully carried on by them for many years, and of which the engagement of its members for a time in special service connected with the organization of the Westinghouse Electric Company, necessitated a discontinuance.

I have now associated with me, Mr. Robert H. Read, formerly Examiner in the Department of Electricity in the United States Patent Office, who for years past has conducted with marked ability and success, the Patent Bureau of the *Electrical Review* of this city. As an expert practitioner in the abstruse and difficult departments of electrical work, especially alternating and multiphase machinery and distribution, Mr. Read has won a deservedly high professional reputation.

Mr. Edward H. Rogers, formerly of counsel for the Westinghouse Electric Company, and favorably known to the profession from his connection with some of the more prominent electrical patent cases which have been before the Federal courts with the past few years, continues his association with us, so that his services may be availed of by our clients in the prosecution or defence of actions for infringement or for advice relating thereto.

The new firm of Pope, Read & Rogers, have fitted up commodious offices at 41 Cortlandt street, New York, and have provided every needful facility for the *prompt dispatch* of all business which may be entrusted to their care.

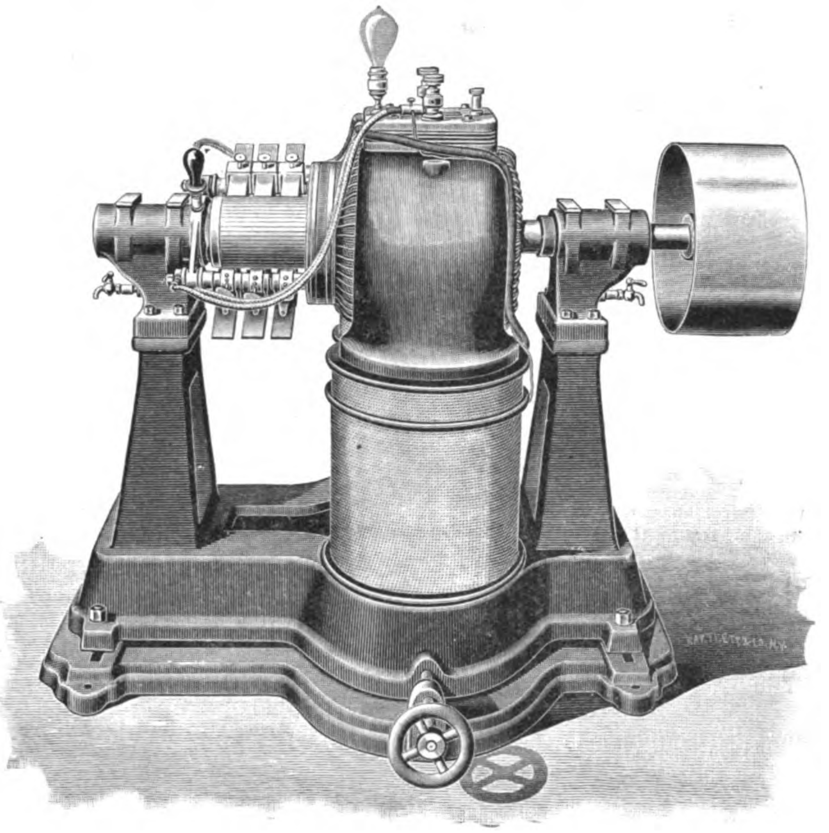
We would especially tender our professional services to parties who desire to obtain adequate and complete patent protection for *complicated, difficult* and *important* inventions, for dealing effectively with which class of cases we feel confident that the long and varied experience of both Mr. Read and myself in all classes of electrical work has given us exceptional qualifications.

Yours very truly,
FRANKLIN L. POPE.

41 Cortlandt street, N. Y., May 25.

Valves and Hydrants at the Exposition.

The Chapman Valve Manufacturing Company have an extensive and attractive exhibit of their goods at the World's Columbian Exposition, including a varied display of Straightway Valves and Hydrants. The location of their exhibit in Machinery Hall is Main 26, K-28. The company has an attentive representative in charge there, and they cordially invite persons intending to visit the Exposition to call and inspect their exhibit. Jackson Park power station of the Western Dummy Electric Railroad is fitted throughout with their valves.



THE LA ROCHE DYNAMO.

A Busy Manufacturing Company.

The Elektron Manufacturing Company of Springfield, Mass., are experiencing a very lively demand for their improved electric elevators; and for the convenience of customers in Boston and that neighborhood they have recently opened an office at 103 Milk street, that city, and have stationed there Mr. E. Marshall as manager of the elevator department, and Mr. F. B. Corey as manager of the electrical department. These two gentlemen are both experts in their particular departments and will handle successfully any business that may come their way. Mr. Marshall has had a long experience in the elevator business in connection with the Otis & Graves hydraulic and power apparatus.

The Boston office of the Elektron Company has recently installed electric elevators for Messrs Curtis & Bolster 2,304 Washington street, and Frank Ferdinand, 2,280 Washington street, Boston.

The main office of the Elektron Company at Springfield has recently sold electric elevators to the new Masonic Hall, Springfield, Mass., the finest building in the city; Brown, Thompson & Co., dry goods store, Hartford; W. H. King & Son, paper dealers, Springfield; the latter order being the second from that well-known firm.

New Use of the Lundell Fan Outfit.

Amusement seekers during the hot summer months will appreciate the liberality of the management of the Fifth Avenue Theatre and actors will bless it when they feel the cooling zephyrs that make this theatre a delightful resort. This invisible, inaudible delight is the result of experiments with a fan motor outfit. The Lundell outfit was chosen, particularly on account of its noiselessness. The boxes will have each an individual outfit and there will be a plentiful distribution of fans throughout the auditorium, stage and dressing rooms. The Interior Conduit and Insulation Company, whose wiring system is installed in the building, furnish the Lundell fan outfits.

The Lundell Fan Motor.

A neat little catalogue, wholly devoted to the Lundell Fan Motors, has just been issued by the Interior Conduit and Insulating Company, who are the manufacturers of the motors. The several illustrations given show the form and construction of the motor and its parts, which are fully described in the letterpress. Among the merits claimed for the Lundell Fan Motors are: Novelty of design, ideal shape, compact and clean appearance, no leakage of magnetic lines of force, highest efficiency attainable, small weight, no sparking at the brushes, steady point of commutation, simplicity and noiselessness. The motors are superbly finished in rich black japanning with neat red and gold striping.

The Premier-DeMott Battery.

BROOKLYN, April 17, 1893.

MR. M. R. RODRIGUES, Brooklyn, N. Y.

Dear Sir: A careful test of a cell of your Premier-DeMott Blue Stone Battery, set up April 5, inst., shows it to be capable of delivering a practically constant current, on short circuit, of 2.89 amperes, electromotive force of 1.079 volts, the internal resistance being less than one-half of an ohm (.45.) Yours, etc.

EDWARD BLAKENEY.

COMMERCIAL PARAGRAPHS.

Mr. Paul Firdler, of the Boston Braid Company, has gone out West on an important business trip, and will be away about a fortnight. He is accompanied by Mrs. Firdler. Before their return they will visit the more important Western cities.

The Consolidated Electric Manufacturing Company is now rushed with orders for their new type arc light machine with Elkins regulator. This dynamo is a radical departure from any other machine on the market and bids fair for becoming a favorite. Its beauty of design and high efficiency in service recommend it every time.

The Whitney Electrical Instrument Company, whose chief office is in Boston, with factories in Penacook, N. H., and Sherbrooke, P. Q., Canada, has just issued a very handsomely illustrated catalogue and price-list of its voltmeters, ammeters, indicators and other instruments for accurate measurement in the electrical business These well known instruments have won a prominent place in popular favor and the demand for them is daily on the increase.

The Campbell Electrical Supply Company, 104 High street, Boston, has been appointed New England agent for the La Roche Motor Company, Philadelphia, and now has on exhibit some of those handsome and efficient motors.

Mr. F. S. Palmer, general manager of the Electric Heat Alarm Company, Boston, has an attractive exhibit at the World's Fair, and in order that visitors shall fully understand and appreciate the value and usefulness of this unique device, he has had circulars and cards printed in three languages, viz., English, French and German.

Those station managers who realize the value of standardized fuse wire may be interested to know that the Wirt fuse wire handled by the Ansonia Electric Company, formerly the Electrical Supply Company, is standardized wire.

The large sales which the Ansonia Electric Company, formerly the Electrical Supply Company, are making of Shield Brand Wire, Stanley Transformers and Helios Lamps would tend to prove that it is a combination which operators of plants think very highly of.

A very neat little pamphlet has recently been issued by the Ansonia Electric Company, descriptive of the W.-W. Lightning Arrester, which ought to be of interest to every station superintendent or manager.

The New Sunbeam Incandescent Lamp which is being manufactured by the Star Electric Lamp Company is proving much superior to the old vacuum lamps. The gas uniting with the carbon when incandescent prevents the drop of candle power which was unavoidable in the old style of lamp, and maintains the lamp at full initial candle power throughout its life. Orders are coming in in increasing quantities, showing that the electrical fraternity appreciate the successful efforts of the Star Electric Lamp Company to supply an entirely new incandescent lamp which shows a great step in advance in the art.

The Railway Equipment Company, Chicago, reports contracts made for type "G" overhead material during the last few weeks with the Tiffin [O.] Electric Railway Company; Belle City Street Railway Company, Racine, Wis.; Norristown [Pa.] Electric Railway Company; South Chicago City Railway Company; Mobile [Ala.] Electric Light and Power Company; Camden and Atlantic Railroad Company, Atlantic City and Camden, N. J.; Calumet Electric Street Railway Company, Chicago; Trenton [N. J.] Iron Company; Columbia [Pa.] and Ironville Street Railway Company; Lehigh Traction Company, Hazleton, Pa.; Wheeling [W. Va.] Railway Company; Wichita [Kan.] Electric Railway Company; Fox River Street Railway Company, Green Bay, Wis.; Pottstown [Pa.] Passenger Railway Company; Wyandotte and Detroit River Railway Company, Ecorces, Mich.; Cumberland [Md.] Electric Railway; Montreal [Can.] Street Railway; Independence [Iowa] and Rush Park Railway; Westminster and Vancouver Tramway Company; Gettysburg [Pa.] Electric Railway; Second Avenue Passenger Railway, Pittsburg; Pittsburg and West End Passenger Railway; Escanaba [Mich.] Electric Street Railway Company; Atlantic Avenue Railroad Company, Brooklyn; Hammond [Ind.] Electric Railway Company.

INCORPORATIONS.

The Pleasure Resort Railway Company, Denver, Col. Capital stock, $100,000. Directors: L. F. Kimball, E. E. Somers, William Thorne, E. C. Skiles and Charles E. Skiles. The proposed line will start at the loop in North Denver and will be an electric line. It will extend to Rocky Mountain Lake.

The Rhinebeck Electric Light and Power Company of Rhinebeck, N. Y. Capital stock, $5,000. Directors: Thomas J. Swift and James L. Williams, of Poughkeepsie, and Allen H. Hoffman, of Rhinebeck.

The Kankakee Power Company, at Kankakee, Ill.—for the development of water and electric power. Capital stock, $100,000. Incorporators: William C. Thompson, John C. Smith and Antoine J. Bedard.

The Milford Electric Light and Power Transmission Company, Milford, Ill. Capital stock, $15,000. Incorporators: Henry V. Brown, Eugene W. Whipple and William H. Megg.

The Rochester and Irondequoit Railway Company—to build and operate an electric railway in North St. Paul street, Rochester, N. Y., to extend to Windsor Beach. Capital stock, $1,000,000. Directors: J. N. Beckley, Frederick Cook, W. S. Kimball, W. C. Barry, W. D. Ellwanger, Max Brickner, Jacob Gerling, Henry C. Brewster, Frank S. Upton, Louis Greishhimer, George W. Archer, Bernard Dunn, Fred W. Smith, of Rochester; Benjamin Graham, of New York, and M. A. Verner, of Pittsburg.

The Tiffin [Ohio] and Fostoria Railway Company has organized and elected officers as follows: Directors, Hon. George E. Seney, Milton Sayler, R. W. Brown, Hon. John McCauley, H. J. Weller, J. H. Platt and R. J. Beatty, of Tiffin, and Alonzo Emerine and Jeremiah Kestlerode, of Fostoria: president and treasurer, R. W. Brown: vice-president, Alonzo Emerine; secretary, Milton Sayler.

Centralia Light and Power Company, Centralia, Ill. Capital stock, $31,000. Incorporators; Seymour Andrews, F. Kohl and George L. Grittinger.

The Norwich Light and Power Company, formed to operate the gas and electric plant at Norwich, Chenango County, N. Y., recently owned by the Norwich Electric Illuminating Company, has been organized and the following directors elected: Edward F. Murray, of Troy; Senator Louis W. Emerson, of Warrensburgh; Senator Harvey J. Donaldson, County Treasurer Stephen C. Medbery and Herbert C. Westcot, of Ballston. The directors are the sole owners of the plant.

The Electrical Supply and Construction Company of Kansas City, Kan. Capital stock, $10,000. Directors: W. S. Nelson and B. F. Moots, of Kansas City, Mo.; W. H. Campbell, J. F. Frankey and H. A. Young, of Kansas City, Kan.

Consolidation papers of the Cooperstown Gas Company with the Cooperstown Electric Company have been filed with the Secretary of State at Albany, N. Y. The new company, which is to be known as the Cooperstown Gas and Electric Company, is to have a capital of $25,000. The following are the directors for the first year: Charles B. Staats, of Albany; Lee B. Cruttendon, Oliver R. Butler, James Bunyan and Paul T. Brady, of Cooperstown.

The Wagner Electro-Medical Company, at Chicago. Capital stock, $50,000. Incorporators: C. B. Gregg, W. D. Hawk and John S. Goodwin.

The Iowa Electric and Construction Company—to manufacture and sell all kinds of electrical apparatus and have its general office in Des Moines. Capital stock, $100,000. Incorporators: A. T. Hess, J. A. James, J. Steadman, E. C. Spinney, E. C. Pratt and Wm. Bowen. Officers: President, E. C. Spinney; vice-president, E. G. Pratt; secretary, J. A. Innessded; treasurer, Wm. Bowen. It is a reorganization and enlargement of the Hess Electrical Company.

The Wadestown Telephone Company, Wadestown, W. Va.—to construct and operate telephone lines from Wadestown to Burton, Blackstown, Morgantown, Fairmont, Mannington and intermediate points. The principal office will be at Wadestown. The incorporators are T. W. Barr, C. C. Hartner, C. L. Eakin, Asa Henderson and N. G. Garrison, all of Wadestown.

The Muncie Electric Company, Muncie, Ind. Capital stock, $200,000. Incorporators: Aretus W. Hatch, Willard C. Nichols, Edward McDevitt, James C. Devor and Andrew T. Hart. The articles secure the right to run a railway into adjoining counties.

The Mt. Pleasant and Hammondville Electric Street Railway Company, at Harrisburg, Pa. Capital stock, $18,000. Directors: D. P. Lowe, I. J. McWilliams, Monroe Morrison F. H. Sheppard, V. B. Hubbs, H. C. Morrison, of Mt. Pleasant. The road will be three miles long and will run through the borough of Hammondville, Pa.

The following charters were issued last week at Harrisburg, Pa.: The Allegheny Valley Heat, Light and Power Company, New Kensington, Westmoreland County; capital stock, $15,000. Tioga Point Electric Light and Power Company, Athens, Bradford County; capital stock, $8,000. The Electric Light and Power Company, Sayre; capital stock, $3,000. The Towanda Traction Company, Towanda; capital stock, $42,000.

ELECTRICAL PATENT RECORD.

Letters Patent Issued May 23, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

498,046. Electric-Railway Trolley. Edward H. Allen, Cramer Hill, N. J., assignor of two-thirds to William A. Barrett, Jr., Philadelphia, Pa. Filed Nov. 16, 1892.

498,135. Conduit Electric Railway. George F. Moffett, Portland, Ore. Filed Oct. 7, 1892.

498,169. Electric-Railway Conduit. Arthur H. Hieatzman, Baltimore, Md., assignor of one-half to Harry D. Hieatzman, same place. Filed July 28, 1891.

498,189. Electric-Railway Conduit. Joseph L. Reynolds, Winterset, Iowa. Filed July 23, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

497,849. Wall Socket for Incandescent Lamps. Herbert C. Wirt, Boston, Mass., assignor to the General Electric Company, same place. Filed March 7, 1892.

497,898. Electrode-Shield for Arc Lamps. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Nov. 3, 1890.

497,955. Temporary Circuit-Connector for Incandescent Electric Lamps. Gustav A. Frei, Springfield, Mass. Filed Dec. 19, 1892.

497,956. Incandescent Lamp. Gustav A. Frei, Springfield, Mass. Filed Dec. 19, 1892.

497,957. Incandescent Electric Lamp. Gustav A. Frei, Springfield, Mass. Filed Feb. 7, 1893.

498,141. Electrode for Arc Lamp. Albert C. Seibold, Mount Vernon, N. Y. Filed Feb. 28, 1893.

DYNAMOS AND MOTORS.

497,887. Armature for Electric Motors or Generators. James F. McLaughlin, Philadelphia, Pa. Filed Dec. 17, 1891.

497,888. Electric Motor or Generator. James F. McLaughlin, Philadelphia, Pa. Filed July 27, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

497,907. Coin-Controlled Lock for Telephones. Pitt Cooke, Washington, D. C. Filed Dec. 24, 1892.

497 942. District-Telegraph Return-Signal Key. John M. Bell, Tacoma, Wash. Filed Oct. 24, 1892.

MEASURING INSTRUMENTS.

498,021. Electric Current Time-Meter. Henry H. Pattee, Monmouth, Ill. Filed Sept. 6, 1890.

498,022. Electric Current Time-Meter. Henry H. Pattee, Monmouth, Ill. Filed Sept. 6, 1890.

ELECTRIC HEATERS AND DOMESTIC APPLIANCES.

497,771. Electric Heater. Samuel M. Cook, Boston, Mass., assignor to the American Electric Heating Company, same place. Filed Jan. 17, 1893.

497,790. Electric Boiler. Samuel B. Jenkins, Boston, Mass., assignor to the American Electric Heating Company, same place. Filed Oct. 14, 1892.

497,791. Electric Radiator. Samuel B. Jenkins, Boston, Mass., assignor to the American Electric Heating Company, same place. Filed Nov. 25, 1892.

497,792. Electric Flat-Iron Heater. Samuel B. Jenkins, Boston, Mass., assignor to the American Electric Heating Company, same place. Filed Dec. 5, 1892.

497,793. Electric Soldering-Iron. Samuel B Jenkins, Boston, Mass., assignor to the American Electric Heating Company, same place. Filed Dec. 5, 1892.

497,794. Electric Heater for Flat-Irons or other Articles. Samuel B. Jenkins, Boston, Mass., assignor to the American Electric Heating Company, same place. Filed Dec. 5, 1892.

497,795. Electric Heater. Samuel B. Jenkins, Boston, Mass., assignor to the American Electric Heating Company, same place. Filed Dec. 8, 1892.

498,078. Method of Manufacturing Electric Heaters. Henry G. O'Neill, Boston, Mass., assignor to the Standard Electric Heat, Light and Power Company of Maine. Filed Aug. 20, 1892.

MISCELLANEOUS.

497,822. Electro-Therapeutic Appliance. Henry C. Royer, Los Angeles, Cal., assignor of one-half to John E. Reed, same place. Filed Oct. 3, 1892.

497,832. Electric Mining-Machine. Elmer A. Sperry, Chicago, Ill., assignor, by mesne assignments, to the Thomson-Houston Electric Company of Connecticut. Filed Oct. 8, 1888.

497,836. Safety Block System for Railway Signaling. William R. Sykes, Jr., and John P. O'Donnell, London, England. Filed Oct. 1, 1892.

497,838. Safety Appliance for Systems of Electric Distribution. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Jan. 29, 1890.

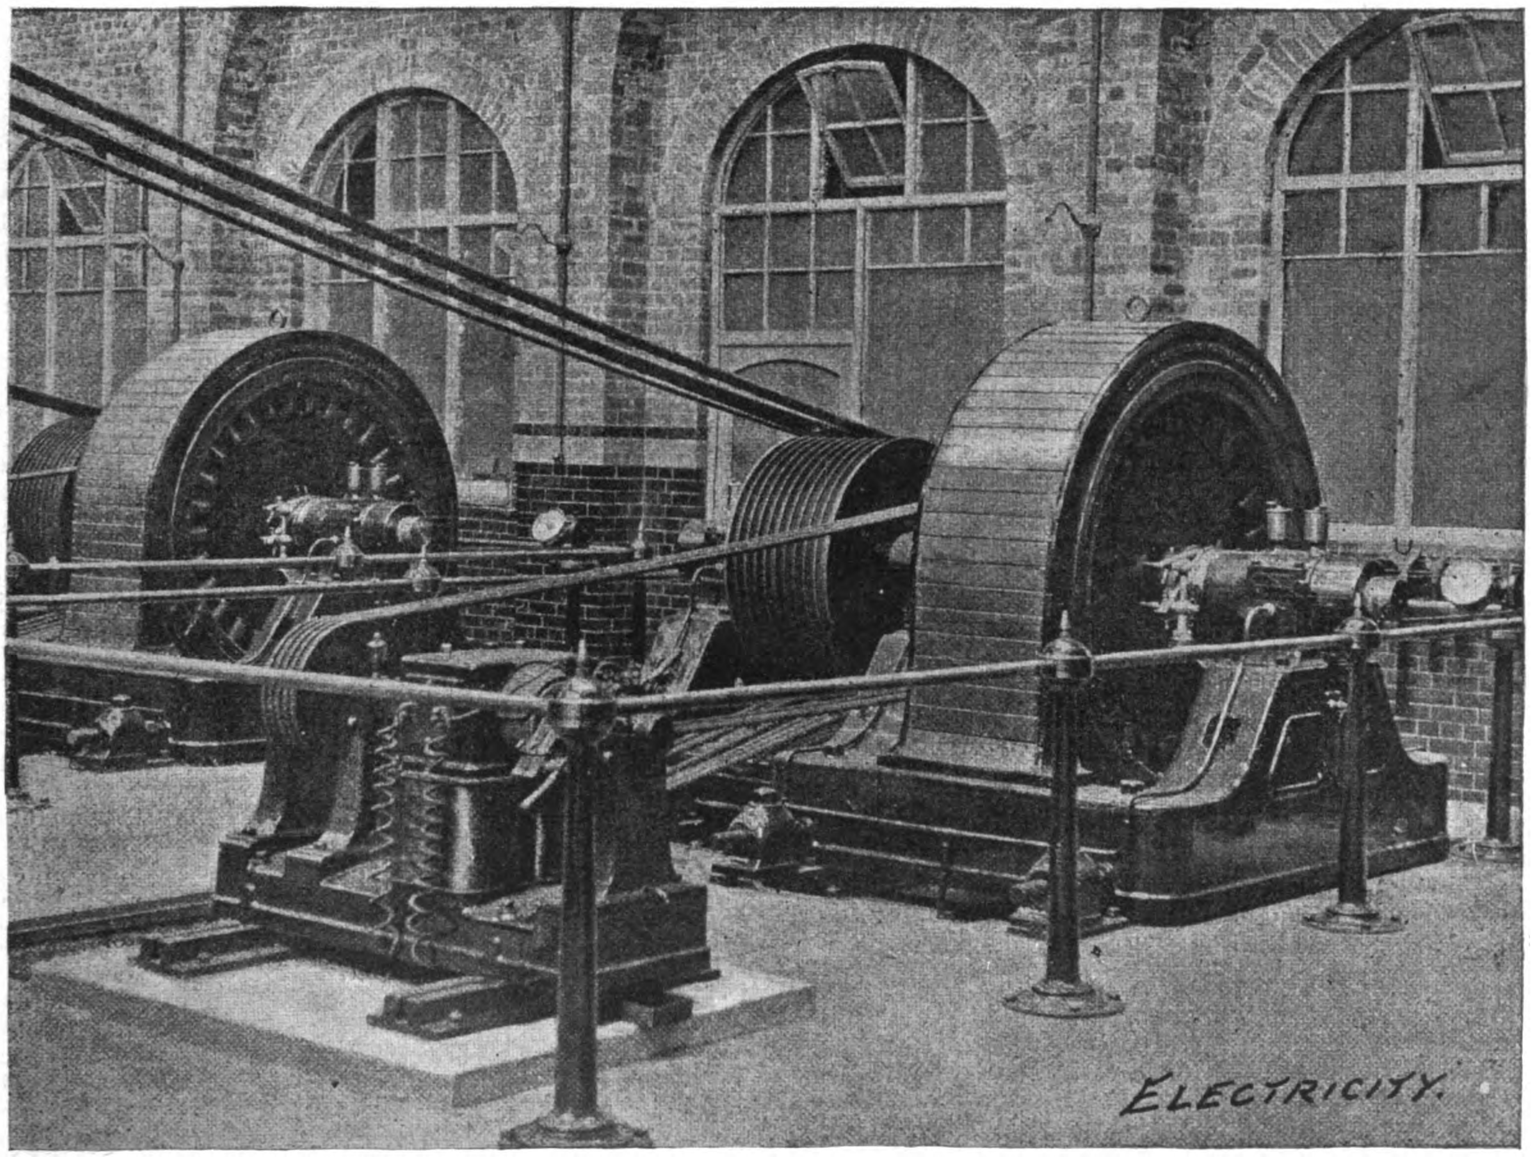
ELECTRICITY.

VOL. IV. NEW YORK. JUNE 7, 1893. CHICAGO. No. 21



DYNAMO ROOM, LEEDS CENTRAL STATION. (SEE PAGE 286.)

The Leeds Central Station.

The inauguration of the Leeds (England) Central Station took place on May 10, and was marked by extensive ceremonies, including a banquet.

The system is a high-pressure alternating-current transformer supply at constant pressure to transformers fixed at first in suitable positions on consumers' premises; but when a sufficient number of services has been secured the distribution will be carried out by means of low-pressure distributing mains fed from converting stations. The distributing mains consist of insulated cables laid in cast-iron conduits underground where possible.

The engine room, shown in Fig. 1, is a large, commodious room 68 feet × 63 feet, which is spanned by a traveling crane of ten tons capacity.

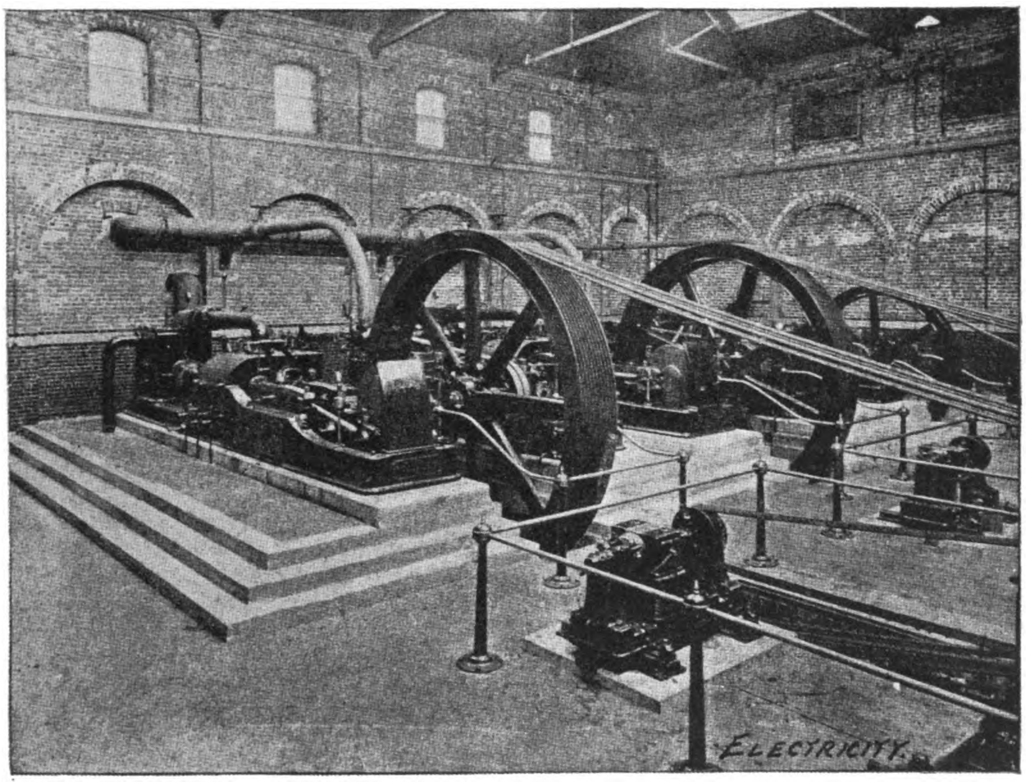


FIG. 1.

The engine room is equipped with two 200 I. H. P. engines driving two 100-kilowatt alternators, and one 100 I. H. P. engine driving a 50 kilowatt alternator. The plant is capable of supplying 7,500 35-watt lamps. The engines are of the horizontal coupled compound condensing type, the size of the larger ones being considered by the engineers to be the most suitable unit to work in sections, having regard to the requirements of the business. The speed of the larger engines is 90 revolutions, the ordinary working pressure is 125 lbs. per square inch, but they will work without difficulty up to 140 lbs., and give each 250 I. H. P. as a maximum load. This provides for a good margin sufficient to meet all possible contingencies. The dimensions of the parts are: high pressure cylinder 14 inches diameter, low pressure 25 inches diameter, and stroke 30 inches. The slide bars do not consist of a cylindrical casting, but are made separate in two pairs to each cylinder in such a way that easy adjustment is possible. The bed plate of the engine is of the most massive construction. A noticeable feature is the strength of the crankshaft and the length and surface of the bearings.

Injection condensers are employed in conjunction with these engines, the air pumps, condenser and hot well being formed in one casting, and fixed to the bed plate at the back of the low pressure cylinder, the air pump being coupled direct to the low pressure piston rod working through the back of the cylinder cover. The engines are so arranged that they can be worked non-condensing in case of any failure of condensing water. They are also fitted with automatic expansion gear, controlled by powerful governors acting on the cut off valves of both cylinders. The fly-wheels of the large engines are 14 feet in diameter.

The alternators, shown in the Frontispiece, are the Lowrie-Parker multipolar type. They are self-regulating to about 16 per cent., this advantage being secured by a simple alteration in the design of the magnetic field. The working pressure is 2,000 volts, and, as in the case of the engines, allows a good working margin. The insulation resistance between the coils and the frame is about 15 megohms. The armatures and field magnet conductors do not carry more than 2,000 amperes per square inch of section. The cables are led away from the switchboard terminals in suitable trenches which are rendered accessible by wooden traps let in the floor.

The exciters for the alternators are driven by ropes from a grooved pulley on the alternator shaft, and are each of ample size to generate a current sufficient for exciting the fields of the corresponding alternator without overheating. The exciting current is about 30 amperes, at a pressure of 120 volts for the 100 kilowatt machines, and 30 amperes at 60 volts for the 50-kilowatt machines.

The Electrical Experiments on the Erie Canal.

Superintendent Hannan has received several applications for permission to use the Erie Canal for experiments in electric propulsion for canal boats. There are 3,500 canal boats, and the electric motors to propel them would probably cost $250 each. The great manufacturers will no doubt enter into the competition announced by Superintendent Hannan. John Alden, of Rochester, one of the applicants, will use the power of the Westinghouse Electric Light Company at Rochester. Another inventor desires to have a trial at Schenectady, the headquarters of the General Electric Company.

Superintendent Hannan says he will employ the $10,000 appropriation partly in paying the salary of some competent electrical engineer who will make a report to him as to the success of the various systems of electrical propulsion proposed.

ON LIGHT AND OTHER HIGH FREQUENCY PHENOMENA.

BY NIKOLA TESLA.* (*Continued.*)

It is beyond the scope of my lecture to dwell upon the subject of light in general, my object being merely to bring presently to your notice a certain class of light effects and a number of phenomena observed in pursuing the study of these effects. But to be consistent in my remarks it is necessary to state that according to that idea, now accepted by the majority of scientific men as a positive result of theoretical and experimental investigation, the various forms or manifestations of energy which were generally designated as "electric," or more precisely "electromagnetic," are energy manifestations of the same nature as those of radiant heat and light. Therefore the phenomena of light and heat, and others besides these, may be called electrical phenomena. Thus electrical science has become the mother science of all, and its study has become all important. The day when we shall know exactly what "electricity" is will chronicle an event probably greater, more important, than any other recorded in the history of the human race. The time will come when the comfort, the very existence perhaps, of man will depend upon that wonderful agent. For our existence and comfort we require heat, light and mechanical power. How do we now get all these? We get them from fuel; we get them by consuming material. What will man do when the forests disappear, when the coal fields are exhausted? Only one thing, according to our present knowledge will remain; that is, to transmit power at great distances. Men will go to the waterfalls, to the tides, which are the stores of an infinitesimal part of Nature's immeasurable energy. There will they harness the energy and transmit the same to their settlements, to warm their homes by, to give them light, and to keep their obedient slaves, the machines, toiling. But how will they transmit this energy if not by electricity? Judge then, if the comfort, nay the very existence, of man will not depend on electricity. I am aware that this view is not that of a practical engineer, but neither is it that of an illusionist, for it is certain that power transmission, which at present is merely a stimulus to enterprise, will some day be a dire necessity.

It is more important for the student who takes up the study of light phenomena to make himself thoroughly acquainted with certain modern views than to peruse entire books on the subject of light itself as disconnected from these views. Were I therefore to make these demonstrations before students seeking information—and for the sake of the few of those who may be present, give me leave to so assume—it would be my principal endeavor to impress these views upon their minds in this series of experiments.

It might be sufficient for this purpose to perform a simple and well-known experiment. I might take a familiar appliance, a Leyden jar, charge it from a frictional machine, and then discharge it. In explaining to you its permanent state when charged, and its transitory condition when discharging, calling your attention to the forces which enter into play and to the various phenomena they produce, and pointing out the relation of the forces and phenomena, I might fully succeed in illustrating that modern idea. No doubt, to the thinker, this simple experiment would appeal as much as the most magnificent display. But this is to be an experimental demonstration, and one which should possess, besides instructive, also entertaining features, and as such a simple experiment, such as the one cited, would not go very far towards the attainment of the lecturer's aim. I must therefore choose another way of illustrating, more spectacular certainly, but perhaps also more instructive. Instead of the frictional machine and Leyden jar, I shall avail myself in these experiments of an induction coil of peculiar properties, which was described in detail by me in a lecture before the London Institution of Electrical Engineers in February, 1892, This induction coil is capable of yielding currents of enormous potential differences, alternating with extreme rapidity. With this apparatus I shall endeavor to show you three distinct classes of effects, or phenomena, and it is my desire that each experiment, while serving for the purposes of illustration, should at the same time teach us some novel truth, or show us some novel aspect of this fascinating science. But before doing this it seems proper and useful to dwell upon the apparatus employed, and method of obtaining the high potentials and high-frequency currents which are made use of in these experiments.

---

* A lecture delivered before the Franklin Institute at Philadelphia, Feb. 24, 1893, and before the National Electric Light Association at St. Louis, Mo., March 1, 1893.

ON THE APPARATUS AND METHOD OF CONVERSION.

These high-frequency currents are obtained in a peculiar manner. The method employed was advanced by me about two years ago in an experimental lecture before the American Institute of Electrical Engineers. A number of ways, as practised in the laboratory, of obtaining these currents either from continuous or low-frequency alternating currents is diagrammatically indicated in Fig. 1, which will be later described in detail. The general plan is to charge condensers from a direct or alternate current source, preferably of high tension, and to discharge them disruptively while observing well-known conditions necessary to maintain the oscillations of the current. In view of the general interest taken in high-frequency currents and effects producible by them, it seems to me advisable to dwell at some length upon this method of conversion. In order to give you a clear idea of the action, I will suppose that a continuous-current generator is employed, which is often very convenient. It is desirable that the generator should possess such high tension as to be able to break through a small air space. If this is not the case, then auxiliary means have to be resorted to, some of which will be indicated subsequently. When the condensers are charged to a certain potential, the air or insulating space gives way and a disruptive discharge occurs. There is then a sudden rush of current and generally a large portion of the accumulated electrical energy spends itself. The condensers are thereupon quickly charged, and the same process is repeated in more or less rapid succession. To produce such sudden rushes of current it is necessary to observe certain conditions. If the rate at which the condensers are discharged is the same as that at which they are charged, then, clearly, in the assumed case the condensers do not come into play. If the rate of discharge be smaller than the rate of charging, then again the condensers cannot play an important part. But if, on the contrary, the rate of discharging is greater than that of charging, then a succession of rushes of current is obtained. It is evident that if the rate at which the energy is being dissipated by the discharge is very much greater than the rate of supply to the condensers, the sudden rushes will be comparatively few, with long time intervals between. This always occurs when a condenser of considerable capacity is charged by means of a comparatively small machine. If the rates of supply and dissipation are not widely different, then the rushes of current will be in quicker succession, and this the more the more nearly equal both the rates are, until natural limitations incident to each case and depending upon a number of causes are reached. Thus we are able to obtain from a continuous-current generator as rapid a succession of discharges as we like. Of course, the higher the tension of the generator the smaller need be the capacity of the condensers, and for this reason, principally, it is of advantage to employ a generator of very high tension. Besides, such a generator permits the attaining of greater rates of vibration.

The rushes of current may be of the same direction under the conditions before assumed, but most generally there is an oscillation superimposed upon the fundamental vibration of the current. When the conditions are so determined that there are no oscillations, the current impulses are undirectional, and thus a means is provided of transforming a continuous current of high tension into a direct current of lower tension, which I think may find employment in the arts.

This method of conversion is exceedingly interesting and I was much impressed by its beauty when I first conceived it. It is ideal in certain respects. It involves the employment of no mechanical devices of any kind, and it allows of obtaining currents of any desired frequency from an ordinary circuit, direct or alternating. The frequency of the fundamental discharges depending on the relative rates of supply and dissipation can be readily varied within wide limits by simple adjustments of these quantities, and the frequency of the superimposed vibration by the determination of the capacity, self-induction and resistance of the circuit. The potential of the currents, again, may be raised as high as any insulation is capable of withstanding safely, by combining capacity and self-induction or by induction in a secondary, which need have but comparatively few turns.

As the conditions are often such that the intermittence or oscillation does not readily establish itself, especially when a direct current source is employed, it is of advantage to associate an interrupter with the arc, and I, some time ago, indicated the use of an air-blast or magnet, or other such device readily at hand. The magnet is employed with special advantage in the conversion of direct currents, as it is then very effective. If the primary source is an alternate current generator, it is desirable, as I have stated on another occasion, that the frequency should be low, and that the currents forming the arc be large, in order to render the magnet more effective.

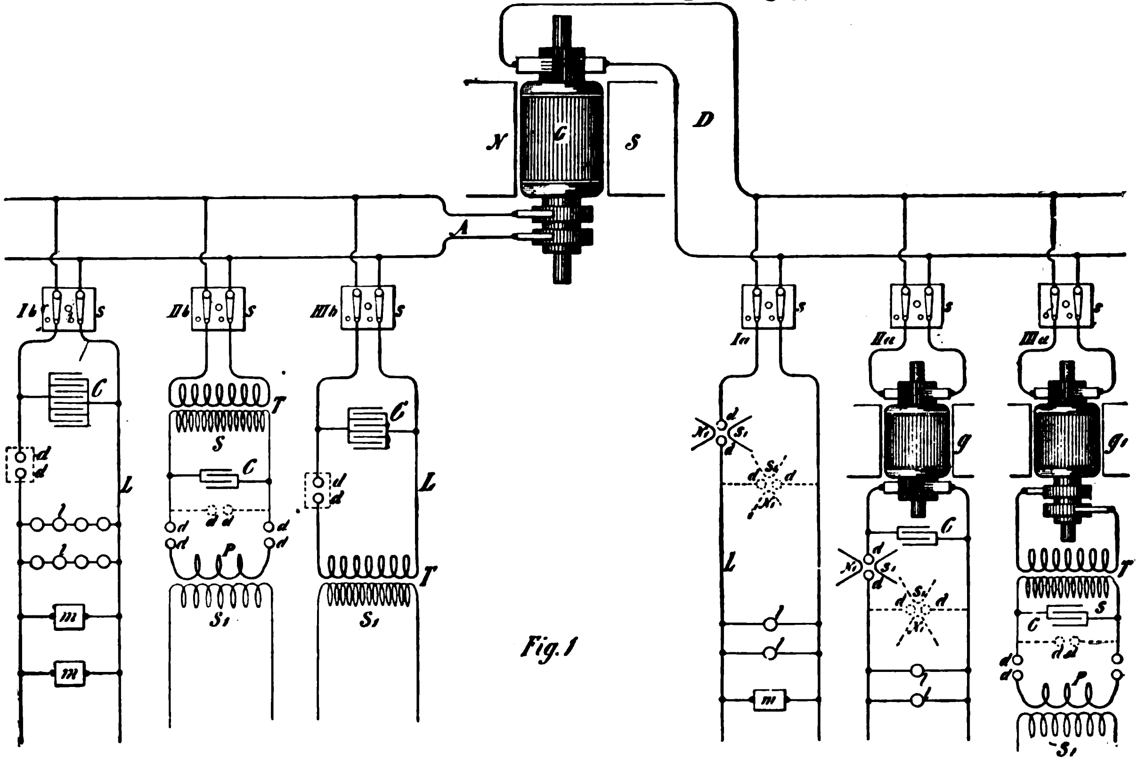

Fig. 1

A form of such discharger with a magnet which has been found convenient, and adopted after some trials, in the conversion of direct currents particularly, is illustrated in Fig. 2. N S are the pole pieces of a very strong magnet which is excited by a coil C. The pole pieces are slotted for adjustment and can be fastened in any position by screws s_1 s_1. The discharge rods d d_1, thinned down on the ends in order to allow a closer approach of the magnetic pole pieces, pass through the columns of brass b b_1 and are fastened in position by screws s_2 s_2. Springs r r_1 and collars c c_1 are slipped on the rods, the latter serving to set the points of the rods at a certain suitable distance by means of screws s_3 s_3, and the former to draw the points apart. When it is desired to start the arc, one of the hard rubber handles h h_1 is tapped quickly with the hand, whereby the points of the rods are brought in contact, but are instantly separated by the springs r r_1. Such an arrangement has been found to be often necessary, namely, in cases when the E. M. F. was not large enough to cause the discharge to break through the gap, and also when it was desirable to avoid short circuiting of the generator by the metallic contacts of the rods. The rapidity of the interruptions of the current with a magnet depends on the intensity of the magnetic field and on the potential difference at the ends of the arc. The interruptions are generally in such quick succession as to produce a musical sound. Years ago it was observed that when a powerful induction coil is discharged between the poles of a strong magnet the discharge produces a loud noise not unlike a small pistol shot. It was vaguely stated that the spark was intensified by the presence of the magnetic field. It is now clear that the discharge current, flowing for some time, was interrupted a great number of times by the magnet, thus producing the sound. The phenomenon is especially marked when the field circuit of a large magnet or dynamo is broken in a powerful magnetic field.

When the current through the gap is comparatively large, it is of advantage to slip on the points of the discharge rods pieces of very hard carbon and let the arc play between the carbon pieces. This preserves the rods and besides has the advantage of keeping the air space hotter, as the heat is not conducted away as quickly through the carbons, and the result is that a smaller E. M. F. in the arc gap is required to maintain a succession of discharges.

Another form of discharger which may be employed with advantage in some cases is illustrated in Fig. 3. In this form the discharge rods d d_1 pass through perforations in a wooden box

B, which is thickly coated with mica on the inside, as indicated by the heavy lines. The perforations are provided with mica tubes $m\ m_1$ of some thickness, which are preferably not in contact with the rods $d\ d_1$. The box has a cover c which is a little larger and descends on the outside of the box. The spark gap is warmed by a small lamp l contained in the box. A plate p above the lamp allows the draught to pass only through the chimney c of the lamp, the air entering through holes $o\ o$ in or near the bottom of the box and following the path indicated by the arrows. When the discharger is in operation the door of the box is closed so that the light of the arc is not visible outside. It is desirable to exclude the light as perfectly as possible, as it interferes with some experiments. This form of discharger is simple and very effective when properly manipulated. The air being warmed to a certain temperature has its insulating power impaired, it becomes dielectrically weak, as it were, and the consequence is that the arc can be established at much greater distance. The air should, of course, be sufficiently insulating to allow the discharge to pass through the gap *disruptively*. The arc formed under such conditions, when long, may be made extremely sensitive, and the weak draught through the lamp chimney c is quite sufficient to produce rapid interruptions. The adjustment is made by regulating the temperature and velocity of the draught. Instead of using a lamp it answers the purpose to provide for a draught of warm air in other ways. A very simple way which has been practised is to inclose the arc in a long vertical tube with plates on the top and bottom for regulating the temperature and velocity of the air current. Some provision had to be made for deadening the sound.

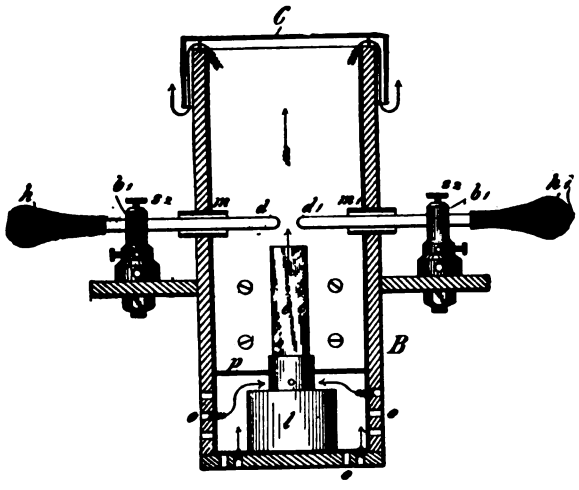

Fig. 3

The air may be rendered dielectrically weak also by rarefaction. Dischargers of this kind have likewise been used by me in connection with the magnet. A large tube is for this purpose provided with heavy electrodes of carbon or metal, between which the discharge is made to pass, the tube being placed in a powerful magnetic field. The exhaustion of the tube is carried to a point at which the discharge breaks through easily, but the pressure should be more than 75 millimeters, at which the ordinary thread discharge occurs. In another form of discharger, combining the features before mentioned, the discharge was made to pass between two adjustable magnetic pole pieces, the space between them being kept at an elevated temperature.

It should be remarked here that when such, or interrupting devices of any kind, are used, and the currents are passed through the primary of a disruptive discharge coil, it is not, as a rule, of advantage to produce a number of interruptions of the current per second greater than the natural frequency of vibrations of the dynamo supply circuit, which is ordinarily small. It should also be pointed out here that while the devices mentioned in connection with the disruptive discharge are advantageous under certain conditions they may be sometimes a source of trouble, as they produce intermittences and other irregularities in the vibration which would be very desirable to overcome.

This is, I regret to say, in this beautiful method of conversion a defect, which fortunately is not vital, and which I have been gradually overcoming. I will best call attention to this defect and indicate a fruitful line of work by comparing the electrical process with its mechanical analogue. The process may be illustrated in this manner: Imagine a tank with a wide opening at the bottom which is kept closed by spring pressure, but so that it snaps off *suddenly* when the liquid in the tank has reached a certain height. Let the fluid be supplied to the tank by means of a pipe feeding at a certain rate. When the critical height of the liquid is reached, the spring gives way and the bottom of the tank drops out. Instantly the liquid falls through the wide opening, and the spring, reasserting itself, closes the bottom again. The tank is now filled and after a certain time interval the same process is repeated. It is clear that if the pipe feeds the fluid quicker than the bottom outlet is capable of letting it pass through, the bottom will remain off and the tank will still overflow. If the rates of supply are exactly equal, then the bottom lid will remain partially open and no vibration of the same and of the liquid column will generally occur, though it might, if started by some means. But if the inlet pipe does not feed the fluid fast enough for the outlet, then there will be always vibration. Again, in such case, each time the bottom flaps up or down, the spring and the liquid column, if the pliability of the spring and the inertia of the moving parts are properly chosen, will perform independent vibrations. In this analogue the fluid may be likened to electricity or electrical energy, the tank to the condenser, the spring to the dielectric and the pipe to the conductor through which electricity is supplied to the condenser. To make this analogy quite complete it is necessary to make the assumption that the bottom, each time it gives way, is knocked violently against a non-elastic stop, this impact involving some loss of energy, and that, besides some dissipation of energy results, due to frictional losses. In the preceding analogue the liquid is supposed to be under a steady pressure. If the pressure of the fluid be assumed to vary rhythmically, this may be taken as corresponding to the case of an alternating current. The process is, then, not quite as simple to consider, but the action is the same in principle.

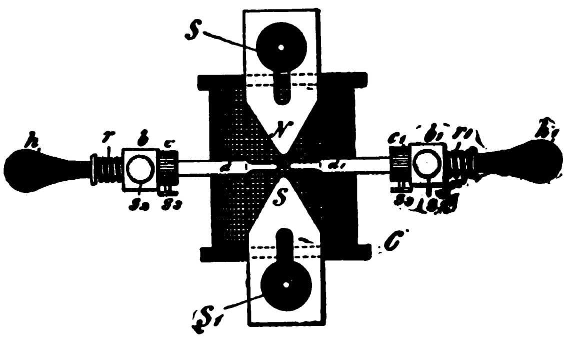

Fig. 2

(To be continued.)

The new telegraph and telephone lines for the New York police, fire and hospital services are now nearly completed, and will soon be in operation.

Revolution in Electric Heating.†

The State Department has just received from United States Consul General Frank M. Mason, at Frankfort, an interesting report concerning a discovery recently announced from Brussels and tested at Berlin, so original and so wide in its practical application that it is believed that it will open a new and important chapter in the use of electricity for heating purposes.

The invention is the joint achievement of two Belgian scientists, Messrs. Lagrange and Hoho, who a few days ago applied to the Imperial German Patent Office for patents on a new method of heating, melting and refining metals by means of electrical heat. The means, as designated in their claim, were so simple and the results as therein described so incredible that the patent examiners demanded that before issuing the patent a practical demonstration of the process should be made in their presence. The matter was referred to an eminent and disinterested electrical expert at Berlin, who made the first essays in his private laboratory and was so delighted with the result that he asked by telegraph permission of the inventors to repeat the demonstration before the Electro-Technical Society at the German capital. Permission was readily granted, and the experiments were performed before the group of expert electricians with brilliant success. From the account given by one of the experts who were present at these demonstrations and from various other sources the following report of the new process has been derived:

The apparatus consists of a glass or porcelain vase, which may be of any size conveniently adapted to the purpose, provided with a lining of lead connected with a strong conductor of positive electricity. The vase is filled to three-fourths its capacity with acidified water. A pair of iron tongs with insulated handles is attached by a flexible conductor to the negative pole of an electrical current generated by an ordinary dynamo. With this simple and inexpensive equipment the following phenomenon is produced.

The electrical current having been switched on, a bar of wrought iron or other metal is taken up with the tongs and plunged into the water within the vase. Immediately the water begins to boil at the point of contact; the immersed portion of the iron rises quickly to a red, then to a white, heat, and emits a stream of brilliant white light. In a few moments the heat becomes so intense that the iron melts and falls off in bubbles and sparks, leaving a clear, glowing surface in perfect condition for welding. The heating process has been so rapid that neither the water nor the end of the bar held within the tongs has been more than slightly warmed, and the current being switched off, the bar, with its submerged and glowing ends, may be readily held in the naked hand. If, instead of a bar of metal, a stick of carbon is used, the heat in a few minutes produces detached fragments of amorphous carbon, which proves scientifically that a temperature of 4,000 degrees Celsius has been developed. The rapidity of the heating and the limit of temperature to be reached are easily and accurately governed by the strength of the current employed, so that the whole process is under the absolute control of the operator. During the recent experiments at Berlin the measuring instruments registered a tension of 120 volts and an energy of 220 amperes. It was estimated that fully 50 per cent. of the current was directly utilized as heat, and at a still stronger current a temperature of 8,000 degrees Celsius has been developed. The importance of this fact will be apparent when it is remembered that this is a degree of heat nearly three times greater than that required to extract iron from the ores, the most refractory of which fuse at about 2,700 degrees.

---

†From advance sheets of U.S. Consular Reports for June.

Divested of all technical phraseology the process under consideration may be explained as follows: One of the well-known effects of electricity is to separate compound fluid bodies through which it passes into their primitive elements. The current, passing through the tongs and metallic bar into the water, decomposes the latter into its two gaseous elements—oxygen and hydrogen. The oxygen is attached and gathered on the relatively large surface of the lead lining, and produces no noticeable effect. The hydrogen, on the other hand, gathers around the immersed portion of the bar; and as this has a comparatively limited surface area, it is immediately surrounded with a close envelope or jacket of hydrogen, which, being a bad conductor of electricity, creates a powerful resistance to the passage of the current and thus develops the heat which causes the bar to glow and melt. It is merely an application of the well known law that friction or resistance to the passage of an electrical current causes heat.

It is as yet too early to form any definite estimate of the practical range of this discovery or its commercial value. Thus far it has been applied experimentally only to the welding of various metals, but with such success that it promises, in that special field, to inaugurate a complete revolution.

All these former difficulties in electric heating are apparently completely mastered by the newly discovered process above described. For welding purposes it is pronounced perfect. The clean envelope of hydrogen which surrounds the heated metal prevents oxidation, and the welding surface is left free from the effects of sulphur and other impurities which are always present when iron is heated by a coal fire in an ordinary forge. The quality which entails the largest possibilities, and which has been as yet only superficially investigated, is the capacity of this process to heat quickly and to any desired temperature the end or submerged surface of a mass of iron while the remainder of the mass is left cool and comparatively unaffected by the heat. It is believed that this may lead to important results in the hardening and tempering of armor plates and other objects in iron and soft steel in which great resistance to penetration or abrasion by friction is requisite while preserving the interior tough and fibrous to resist concussion or strain, as in many parts of machinery. At Essen, Messrs. Krupp & Co. are experimenting with it in the hardening of steel cannon; and it is believed that in chemistry this method of producing an intense and easily regulated temperature may lead to the successful manufacture of diamonds, rubies and sapphires through the production of the larger forms of crystallized carbon.

The Hawaiian Cable Survey.

The results of the survey made by the Albatross party to determine the practicability of laying a cable between California and the Hawaiian Islands have been printed in the form of an elaborate report, illustrated with numerous drawings showing the routes surveyed and matters incidental to the soundings.

According to the report submitted to the Hydrographic Office, the most feasible route is a lane about 300 miles wide between Monterey Bay and Honolulu. Soundings were taken in general at alternate intervals of ten and two miles between Salinas Landing in Monterey Bay and Honolulu and between Point Conception and Hilo Bay, and along a rhomb line between Salinas Landing and Honolulu. Specimens of the bottom of the sea were obtained at each sounding, and the temperature of the air and the surface of the ocean were observed. The density of the sea water was frequently taken by observations at the surface and at depths ranging from 25 to 1,000 fathoms. Whenever, by reason of a notable change in the depth or in the character of the bottom soil, there were reasons to suspect any important irregularity in the bed of the ocean, numerous soundings were taken to provide for an examination of the locality in detail.

The total length of the lines sounded was 4,511 miles; the mean intervals between the soundings were 8.1 miles; total distance steamed in connection with the survey, 8,735 miles; number of soundings made with wire, 502; number made with hand line, 54.

In the shallow waters of the Hawaiian Islands the temperature was found to be about 77 degs. in winter, and, as a gutta percha core may sustain deformations sufficient to bring about a weakening of the insulation on this account, the experts on the Albatross recommend the employment of another insulation material at that end of the line.

World's Fair Notes.

The Electricity Building at the World's Fair has at last been formally opened to the public. The event took place Thursday evening of last week, and although the weather was threatening, a large crowd was attracted by the electrical display promised. The Edison tower, located in the center of the building, proved to be the leading feature of the exhibits. In time with the music from a band of fifty pieces, stationed in the balcony, the light was made to chase up and down and zigzag across the column and at the same time change to several colors. As it is necessary to have an attendant present to operate the lights, the display was shown at intervals of fifteen minutes. It was admitted by all present that the display was one of the most brilliant ever seen in the electrical line.

Last Saturday evening was the opening night for the battle-ship. The public was invited to inspect the model warship, and among other things to see the various applications of electricity to modern warfare. Among the applications illustrated on the ship were the searchlights, the training of guns, the telephone and the illumination of the decks and cabins by both arc and incandescent lights.

On account of several of the dynamos not being ready for use, a number of the circuits intended for illuminating the various buildings have to be cut out during certain portions of the evenings on which the Fair is opened. A large number of the exhibitors have entered complaints about the lights being suddenly turned out in the parts of the building where their exhibits are located, but as there is no remedy until the machines are in shape to generate current their complaints are without avail.

There is one exhibit in the Electricity Building which can be certainly depended upon to always draw a crowd—that is, if the ordinary street hand-organ can be taken as a criterion. It is located in the northeast balcony, and is composed of a number of pianos and automatic organs. The latter instruments can be distinctly heard in any part of the building when the crank is turned by a sturdy employé.

The Western Electric Company will soon have their large multipolar generator, the base of which was accidentally broken when it was being installed, in operation in the generating station of Machinery Hall.

For the convenience of spectators desiring to visit the Ansonia Electric Company's booth, they have erected an elevator operated by an electric motor at the north end of the Electricity Building.

Among the exhibits which were operated for the visitors last week was that of the K. A. P. Electric Novelty Company. It consisted of a number of incandescent lamps mounted on an endless belt, which runs over two pulleys located at some distance from each other. The effect of the revolving colored lights forms a very pleasing subject for the eye.

Electrical Railway in Paris.

It is now some five years since the project of uniting the Bois de Boulogne and the Bois de Vincennes by means of an electric underground railway was first mooted in the French capital. Last year the Municipal Council accorded the concession as a work of public utility, and nothing but administrative formalities require to be complied with in order to place the project upon a sound working basis. It may be interesting to our readers to briefly describe what our neighbors on the other side of the Channel are doing with regard to this particular system of intercommunication. Owing to the nature of soil, and the numerous disturbances, amounting in many instances to absolute excavations, to which the upper stratum in Paris has been so frequently subjected, it is considered as highly dangerous to construct the subway or tunnel in masonry of even the best description. Another reason for abandoning the time-honored method is that it would be impossible to employ it without breaking up the surface of the roads and thoroughfares overhead, which the exigencies of a large and incessant metropolitan traffic do not permit of. In deference to these objections, cast-iron has been selected for the gigantic tube which will constitute the subway, and the circular form has been adopted for its section. The diameter of the tunnel will be twenty feet, which will ensure ample ventilation and passenger accommodation. A double line will run through the subway, and each train will be composed of four carriages or coaches succeeding one another at intervals of two minutes. Seventeen stations upon a total length of seven miles will occasion a large number of stoppages; but the time from one terminus to the other is calculated to be effected in three-quarters of an hour. This velocity is about the same as that at which our own electric line runs. A uniform fare of 20 centimes, equivalent to about two pence [four cents], will be charged, irrespective of the distance traversed. The motive force necessary for the adequate working of the line will be heavy. Steam-power of 4,000 horses will be required to generate electricity for the tractive power, as well as for the lighting of the subway. The generating station will be close to the site of the old Bastile. For the people, especially the working population, the new railway will be of the greatest advantage.—*Electricity* (London).

Current Items.

The Automatic Telephone and Electric Company of Canada intend, it is said, to lay a line of copper wires on the metallic-circuit plan from Halifax, N. S., to Vancouver. This is a distance of 3,500 miles. The circuit will be in sections, and be available for communication to many intermediate points.

A dispatch from Helena, Mont., states that Supt. Sommers, of the Rocky Mountain Bell Telephone Company, is building a telephone line between Livingston and Missoula. It will be a metallic or two-wire circuit and furnished with the latest improvements in long-distance transmitters, etc., and will be one of the best constructed long-distance lines in the Northwest.

A new invention is reported having for its aim the saving of waste in woollen and worsted mills. The device as described consists of a square wooden tank, about 6x6. Suspended in the upper part of this tank is a receiving box. Into this box is put the waste generally found in the mill, such as floor sweepings, waste from beneath the dusters, etc. The bottom of the receiving box is made of netting, and it is swung to and fro mechanically, the dust, etc., falling through. This leaves the waste, pieces of sticks, straw, etc., in the top. Now the action of the electrical current, which is obtained by a series of wires just above the receiving box, causes the wool fibres to separate from the refuse matter, and raise sufficiently to meet a current of air produced by a fan, by which they are carried off and saved.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - -	$ .10

ADVERTISING RATES:
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.
Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Facts.

It is just about nine months since ELECTRICITY, under new ownership, adopted a vigorous policy in regard to the Electric Trust and its proposed monopoly in the business. How effective this policy has been in preventing the accomplishment of the Trust's objects we leave to our readers to determine in the light of recent events.

Our contention was as follows:

That the Trust was organized on the theory that the entire electrical industry of the country could be monopolized and a majority of smaller concerns either frozen out or compelled to pay tribute. We held that the success of this campaign of extinction meant untold and unjustifiable injury to the smaller concerns, and a practical cessation of development in the art.

And further, that the Trust was ridiculously over-capitalized; that it had neither the manufacturing plants nor earning capacity to justify a capitalization of $50,000,000; that the collapse of the stock in the market was inevitable, and that when it came great and widespread injury to the trade at large would ensue, as capital would be timid about electrical investments generally.

We see no reason to-day to change our opinions on any of these points.

The only possible way for the Trust to earn dividends was to establish a monopoly. This it has not been able to do, and monopoly is as dead as a salted codfish hung up on a nail.

The theory was, of course, that by coming together the T.-H. and Edison companies would do as much or a little more business than formerly, and at a greater margin of profit. This theory has been proved fallacious. The margin of profit is no greater, and the volume of business is below that of the underlying companies last year.

ELECTRICITY is informed upon unquestioned authority that the Trust's business for the year falls a little short of $15,000,000. We believe that this business has been done at an actual loss. But allowing that they have made a legitimate manufacturer's profit of 15 per cent. net, we have, on the basis of $15,000,000 total business, net earnings of only $2,250,000, or $980,735 less than dividend charges for the year. No manufacturer in the trade will dispute that 15 per cent. is above the average net profit, and it is a well-known fact that no concern in the trade is so extravagantly managed as the General Electric Company; to none is the cost of doing business so great in proportion to business done.

In view of all the facts, we stand to our original assertion that the collapse of the Trust is sure to come and is only a question of time. The cash on hand to-day, whether it be $1,000,000 or $10,000,000, will not affect the inevitable result.

The Trust scheme will fail because it is founded on monopoly and extortion and a theory of finance which is fundamentally wrong and unsound.

When the reorganization comes, the water squeezed out, and Mr. Coffin's successor appointed, we shall look for better things.

Until then ELECTRICITY will make no change whatever in its policy or conduct, and we will welcome the opportunity to prove the correctness of our views, the accuracy of our aim.

A Conundrum.

Nothing affords us greater pleasure than to answer the varied questions asked by our constituents from time to time—to supply the information sought by inquiring minds. Now and then we receive one which is a poser, and which cannot be answered off hand. But ELECTRICITY has an editor who is employed for this single purpose, and it is nothing unusual for him to spend a week digging in the Astor or the Lenox Library in order that we may furnish a single subscriber in Arkansaw or Texas, who has not the advantages of these vast repositories of knowledge, with the information which he is seeking.

Among the many inquiries recently received was the following:

> *To the Editor of* ELECTRICITY:
>
> We note that Mr. S. D. Greene appears as one of the complainants against you in an action for libel instigated by the General Electric Company. We also noted some time ago that Mr. Greene assumed to announce the policy of that company. Can you tell us what Mr. Greene knows of the policy of the General Electric Company, of its present condition, or of its business? CURIOUS.

Here indeed was a poser, or rather three posers all in one. There was absolutely no information in this office on these points. Naturally, we were inclined to look to Mr. S. D. Greene himself. But upon looking over some public documents we found what seemed to us conclusive proof that Mr. S. D. Greene knows nothing whatever about the policy, the business, or the present condition of the General Electric Company. Then we turned to the gentleman's friends and business associates. But after a week of diligent inquiry we have failed to learn anything. We are therefore compelled for once to announce that we cannot answer our constituent's questions.

Can any one tell us what Mr. S. D. Greene knows of the policy, the business, or the present condition of the General Electric Company?

* * *

We Will Notify Our Friends.

Since the publisher of ELECTRICITY was arrested on the charge of libelling the General Electric Company the mail received at this office has been not only voluminous but highly interesting. Comments on the situation are as varied as the localities from which they come, but perfect unanimity is expressed by our correspondents on one point: they all want to know when the trial is to be, and to hear what Mr. Coffin will have to say in regard to the affairs of the General Electric Company. There is a general expectation that the information elicited from Mr. Coffin by a rigorous examination will be of universal interest, and worth a trip from Chicago to hear.

* * *

CAPT. EUGENE GRIFFIN has denied in the *Evening Post* the statement which we attributed to that paper last week, that "the officers admit that a few weeks ago the company's financial situation was precarious," and that the cash on hand was reduced by $1,500,000 in two weeks.

* * *

WE HAVE little doubt that the General Electric Company will pay its July dividend promptly. But, in view of recent events, we urge Mr. Coffin to state plainly to his stockholders and to the public whether that dividend is paid out of earnings this year, or whether it is paid from the proceeds of sales of treasury assets.

Electricity for Canals. The use of electric propulsion for boats on canals has been often suggested, and has come to be regarded as a perfectly simple suggestion, all that is necessary, according to many of the promoters of the scheme, being to establish a trolley line for the boats and fit them up with propellers or paddle wheels. The New York Legislature, we believe, has passed a law permitting inventors to make trials of their inventions in this line on the canals under proper supervision, apparently ignoring or forgetting the trouble which similar attempts with steam propulsion brought about some years ago.

It is scarcely possible that any scheme involving the use of propellers will be found practicable, as the wash of the water has sooner or later broken down the banks of the canals in all the experiments which have been tried.

If any plan of electric propulsion is to be a success, the propelling power must be placed outside the water, or at least so applied that any damaging wash may be avoided.

* * *

High Speed Electric Railways. Considerable is being written at present concerning high-speed electric traction, and the possibility of running trains at a rate of 150 or 200 miles an hour. The subject has been considered heretofore from an engineering standpoint, but it presents another phase which is of equal importance, that has certainly not received the consideration which it merits. We allude to the practical utility of such a road, and the demand for this sort of service. In considering the subject from this point of view it seems as though there are but few locations where such a speed would be demanded, and as the expense of travelling at such a rate must be far more than by the moderate speed steam roads, there is a probability that a great majority of passengers would content themselves with the latter. The question therefore arises whether such speeds can be attained with financial success, and by this alone will the success of high-speed roads be determined.

The engineering problems, though by no means solved as yet, are not so great as to be considered at all impossible, but the expense of constructing a roadbed to meet the requirements is an unknown quantity, and can be determined only by trial. The power necessary to propel a train at 200 miles an hour is also a quantity to be determined, but both of these are known to be greatly in excess of anything known in present practice. The resistance of the air is another factor which has yet to be determined.

As the demand for roads of this character is at best but small, the most prudent policy would seem to be to attain these speeds by means of gradual advances in railway improvement, rather than project at once a questionable enterprise which is more than likely to result in financial disaster.

* * *

IT WOULD be well for the officers of the Electric Trust to remember that no newspaper can do serious injury when it is in the wrong; that the only powerful journal is the one conducted with fairness, and whose policy is solidly grounded on TRUTH. No respectable business concern will support a journal which is in the wrong; and if ELECTRICITY had not been in the right it would have been dead long ago.

* * *

IT IS pertinent to remind Mr. Coffin and our other regular readers that the editorials on the Electric Trust which have appeared in these columns from time to time were not evolved from the inner consciousness of the editor of ELECTRICITY alone. They are founded on facts—facts supplied by scores of the best men in the trade, who stand ready to come to the front when called on. ELECTRICITY has made no mistakes.

* * *

A LARGE number of the leading men in the electrical trade have already volunteered their services as witnesses, to tell what they know about the Electric Trust and its methods. It appears to be recognized that the attack of the Trust is not aimed at ELECTRICITY alone, but that it is only another move in the general plan which has for its object the crushing out of all competition and of all criticism.

* * *

"Mr. Coffin has recently advised the agents of his company to be on the outlook for desirable opportunities for investment in the electrical line, as his syndicate has $25,000,000 ready to invest in good properties."—ELECTRICITY, Oct. 5, 1892.

What has become of this $25,000,000? Has it all been invested? Or was this announcement only a bluff?

* * *

THE humorous side of that action for libel cannot have escaped the notice of Mr. Coffin and the other close readers of ELECTRICITY. The Boston *Herald*, the leading paper in Boston and New England, published Mr. Coffin's letter on May 11, making a perfectly excusable error therein. This publication escaped the notice of Mr. Coffin and his friends. Even the financial editor of the *Herald* did not know of the error until his attention was called to it by us three weeks later. But when the matter appeared in ELECTRICITY Mr. Coffin and his fellow directors all read it, and re-read it, and began an action for libel. The whole incident is conclusive proof that we have not exaggerated—*that* ELECTRICITY *is the best read paper in the field!*

How It Happened.

(From the Boston Herald, June 2.)

Attention has been called to a fact, which until now has escaped notice, that there was a fatal omission of the word "fifth" in Mr. C. A. Coffin's reply to a series of categorical questions sent to him by a director of the General Electric Company, as published in the evening edition of this paper on May 11. Mr. Coffin was made to say:

"I can answer categorically to each one of the questions 'no,' except to the first part of your inquiry, and to that I answer 'yes.'"

Now, this should have read "except to the first part of your fifth inquiry," etc., and it did so read in the morning edition of May 12, for which edition proof was read from the original copy, which was reprint.

This matter is revived now to correct any misapprehension which may have arisen from the compositor's blunder, and because a technical paper in New York, or its owner, has been indicted for libel in part at least for republishing on May 17 the correspondence between Mr. Coffin and a fellow-director as it appeared in this paper on the evening of May 11. The *Herald* regrets that a typographical error, for which human frailty was alone responsible, should have temporarily perverted fact and led to unpleasant consequences to any of its readers.

Legal Notes.

Another Lamp Suit.

Suit was begun on Monday in the United States Circuit Court by the Edison Electric Light Company and the Edison Electric Illuminating Company of New York against the proprietors of the Imperial Hotel, the proprietors of the Holland House and others, to restrain them from using in their buildings any other than the Edison incandescent lamp, and also to compel them to pay damages to the Edison Company for the use of tho Westinghouse plant.

Judge Dennis, in the Circuit Court at Baltimore, rendered a decision a few days ago which determines Mr. Bowie's right to provide all necessary appliances to run his electric road on the main business thoroughfare of Baltimore. The decision was in the case of the Baltimore City Passenger Railway Company, which applied for an injunction to restrain the city authorities from interfering with the erection of the trolley poles. The bill was demurred to by the city, and the only question remaining was the construction of the two acts of the Legislature which related to the matter. This Judge Dennis has settled in favor of the railway company.

In the case of Townsend & Brown against the Cloverdale Electric Railway Company, Judge Arrington, in the City Court, in Equity, at Montgomery, Ala., has rendered a decision in favor of the complainants. The court decrees that the Cloverdale Company is indebted to Townsend & Brown in the amount of $138,050, the amount of a judgment recovered by them against the company in December last, with interest on the same from that time, less $50,000, the proceeds of the sale of certain bonds held by Townsend & Brown as collateral security, which sale was made in February last. A sale is ordered by the court within the time allowed by law, of the property of the Cloverdale Company. It consists in real estate in the southern part of Montgomery and the electric street railway and appurtenances.

Referring to the suit brought in the Supreme Court, New York, against Hugh R. Garden and Henry C. Davis, to compel them to account for $250,000 worth of stock of the Consolidated Electric Light Company, which Mr. Treadwell alleges was wrongfully obtained by the defendants, Mr. Garden says: "Mr. Treadwell only holds fifty shares out of 25,000 of the Consolidated Company. He was one of the first stockholders and has been cognizant of all the affairs of the company. When the company was on the verge of bankruptcy and the stock was not worth 50 cents a share, Mr. Davis and I, at the directors' request, made arrangements which placed the company on its feet. Our charges were passed upon by the Board of Directors and I received a letter from the president, Edwin S. Thayer, in which he said my charges were moderate and thanked me for the interest I had shown. Regarding the consolidation with the Westinghouse Company, the transaction was legal and was ratified by the directors and a majority of the stockholders. I can show by the records that Mr. Davis and I saved the company from ruin. The charges are absurd."

The Distribution of Power by Alternate-Current Motors—III.

BY ALBION T. SNELL.*

6. PRACTICAL APPLICATION OF THE DREHSTROM.

With a view of adding to the somewhat scanty practical information on the subject of multiphase working, the author proposes to lay before the Institution a few tests of two Drehstrom machines, designed and built by himself some eighteen months ago. These machines were adapted from material at hand, and were built under restrictions as to cost and time, and thus can only be regarded as rough experimental designs. The dynamo was a Gramme wound 10 unit two-pole shunt machine, designed to give 160 volts and 60 amperes, at a speed of about 1,000 revolutions per minute. Three insulated copper rings, with suitable brushes, were fitted around the commutator and connected to the windings of the armature at points 120 deg. apart. The ordinary commutator and brushes were left intact, so that both direct and triphase currents could be taken from the armature; and the field was separately excited. At a speed of 720 revolutions per minute the frequency was 12 ~ per second. This was afterwards increased to 30 ~ by raising the speed of the armature.

The motor was specially built, and had a laminated ring magnet, with Gramme windings, and a closed circuit armature. It was estimated to give 3 B. H. P. at about 1,200 revolutions per minute, and the gross weight was approximately 300 pounds. The armature plates had holes drilled parallel to the shaft and as near to the periphery as possible without breaking through. In these were placed lengths of No. 4 S. G. W. copper wire, insulated from the plates and soldered at either end to massive copper rings. The field winding consisted of six coils, each containing 68 turns of No. 6 S. W. G. copper wire, and having a resistance of 0.055 of an ohm. Opposite coils were joined in series with each other, so as to make three separate circuits, each of 136 turns and 0.11 of an ohm resistance, which could be connected in star or triangle fashion, as desired. This motor proved to be a very effective machine, having considerable torque at starting, and a speed regulation quite as good as a direct current machine of similar output. The only instrument available for taking electrical measurements were a Cardew voltmeter and a Siemens dynamometer; hence it was not possible to measure the angle of lag, or estimate the true watts. The experiments made with the dynamo and motor are shown in the following curves and tables, which at this stage may be instructive, since they show the order and direction of the difficulties met with in Drehstrom working.

(*a*) *Preliminary Experiments with the Dynamo.*

The three copper rings were connected to points in the winding at 120 deg. apart, the Gramme winding being otherwise untouched. The arrangement is diagrammatically represented by Fig. 14. The field was separately excited by 3.05 amperes, and the speed was kept at 710 revolutions per minute. The load was absorbed by iron spiral resistances with small self-induction. Readings were taken of the direct pressure; the alternating pressure at the ends of the three coils, a_1, a_2, a_3; and the current in each of the three mains, A_1, A_2, A_3 (see Fig. 15, curves 2 and 3). It was found that with the armature unloaded the pressure developed by each coil was practically the same; this was also the case when they were equally loaded (see Fig. 16). But it fell rapidly as the current increased, and so a considerable difference could be made between the pressure of the three circuits by simply giving different loads to each of them. The magnetic induction of the armature core, curve 1, Fig. 15, was calculated from the usual formula, $E_a = \frac{N A n}{10^8}$, where E_a equals the total number of volts in the armature, A the number of turns counted all round the armature, N the total flux, and n the number of revolutions per second. It will be seen that the values of the induction measured were all small. The frequency was 12 per second. These conditions were not the most favorable, it is true, but they showed the detrimental effects of internal resistance and self-induction in not only restricting the output but also in affecting the regulation of the pressure of distribution. It will also be seen that the direct pressure is higher than that of the alternating in the proportion of 158 to 94 on open circuit, and with 20 amperes in each branch (or a total of 1.732 × 20 = 34.64 from the combined circuit) in the proportion of 124 to 70. This difference is to be expected, since the alternating pressure is the average value of 120 deg. of the differential curve of potential; and, further, when the armature is loaded, the self-induction probably increases the difference between the two values. The apparent output, curve 4, Fig. 15, estimated by the product of effective amperes and volts, is found to be a maximum with about 22.5 amperes in each circuit, or 39 in all. The current was next increased in each circuit, so as to find the slope of the external characteristic curve. It was found to steadily fall at about the same slope until 37.5 amperes were reached, corresponding to a torque due to 65 amperes, this current being rather more than that designed for the armature. At this point the belt began to slip, and the experiment was stopped. It is clear that this class of dynamo can be safely overloaded for short periods.

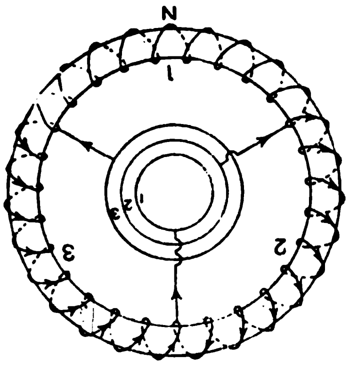

FIG. 14.—Connections of Drehstrom Dynamo, Coils in Series.

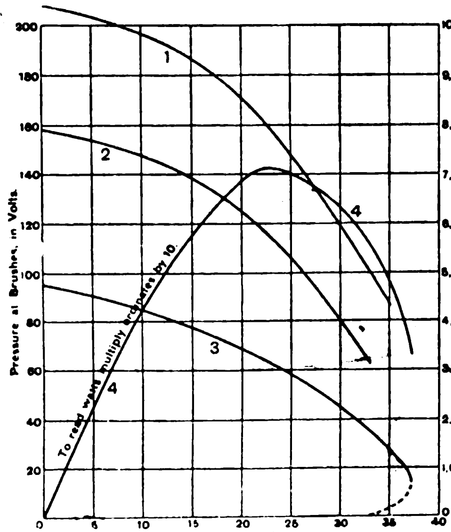

FIG. 15.—Curve 1. Induction in Armature Core. Curve 2. Direct Pressure. Curve 3. Alternating Pressure. Curve 4. Apparent Watts in each Circuit.

The winding of the armature was next divided into six equal parts and opposite sections were joined in parallel (see Fig. 17). The copper rings were then connected as before to points at 120 deg. from each other. Each of the three circuits had now only half as many turns as with the coupling shown in Fig. 14, and one-fourth the resistance. The effect of this alteration was to lower the internal resistance of the armature, and also, presumably, to reduce the self-induction. The excitation was maintained as before at 3.05 amperes, and the speed also at 710 revolutions. The results obtained from the two couplings are shown in Figs. 16 and 18 respectively. It is noticeable that the parallel winding has not materially affected the apparent output of the dynamo. The effective number of turns in each coil is only one-half that with the series winding; and, therefore, for the same heating effect the number of amperes is twice as great. To compare two outputs, then, it is necessary with the series arrangement to take only half as many amperes as with the parallel one. Referring to Figs. 16 and 18, it is found that the apparent watts at 710 revolutions per minute are severally 69 × 20 and 34 × 40, or approximately the same. There was probably a smaller lag of current with the parallel than with the series connections. The smaller pressure and larger current were most suitable for testing the motor, and so the parallel connections of the dynamo armature were used during the whole of the following experiments.

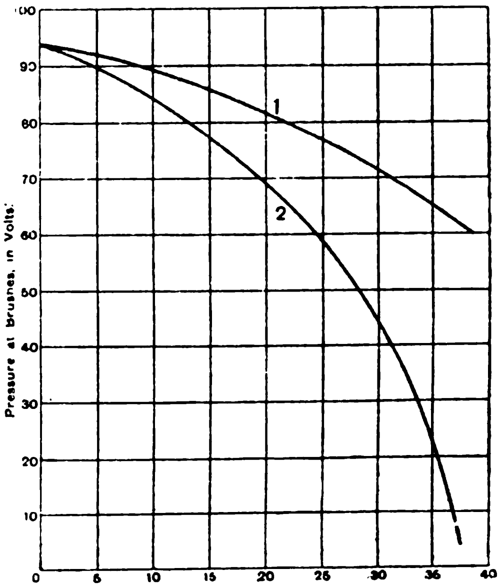

FIG. 16.—Fall of Pressure at Terminals of Drehstrom Dynamo with Armature Coils Coupled as in Fig. 14. Curve 1. Only One Circuit Loaded. Curve 2. All Three Circuits Equally Loaded.

(*b*) *Experiments with the Drehstrom Motor.*

(1) Star or open coil coupling. The motor was coupled to a dynamo by belting and then supplied with current at frequencies ranging between 12 and 33.3 ~ per second. With the lowest frequency the motor ran light at about 700 revolutions per minute, being nearly synchronous with the dynamo. As the load was applied the speed

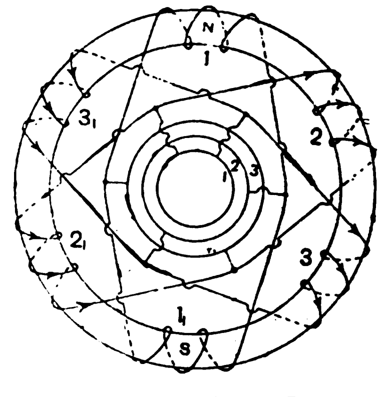

FIG. 17.—Connections of Drehstrom Dynamo, Opposite Coils in Parallel.

---

*Paper read before the Institution of Electrical Engineers, London.

decreased, and since the output was inconveniently small the dynamo speed was raised to about 900 revolutions per minute, when the following readings were taken :

Groups A and B.

No. of test.		Speed of motor.		Pressure on mains.		Amperes in each circuit.		Exciting current in dynamo field circuit.
1	......	848	......	58	......	21	......	2.5
2	......	746	......	55	......	21	......	2.8
3	......	880	......	77	......	38	......	4.5
4	......	800	......	77	......	27	......	Not taken.
1	......	888	......	80	......	28.7	......	4.3
2	......	866	......	80	......	27.6	......	4.3
3	......	824	......	75	......	27.6	......	4.3
4	......	890	......	77	......	28	......	3.9
5	......	790	......	70	......	27.6	......	3.9
6	......	866	......	75	......	27.6	......	3.9
7		Armature held stationary		70	......	34.7	......	3.9

The frequency was about 15 in the above experiments; but the dynamo speed varied from 932 to 833 revolutions per minute, owing to the engine governing badly.

The load on the engine was next adjusted so as give a steady dynamo speed of 960 revolutions, and the tests included in Groups C, D, and E were made.

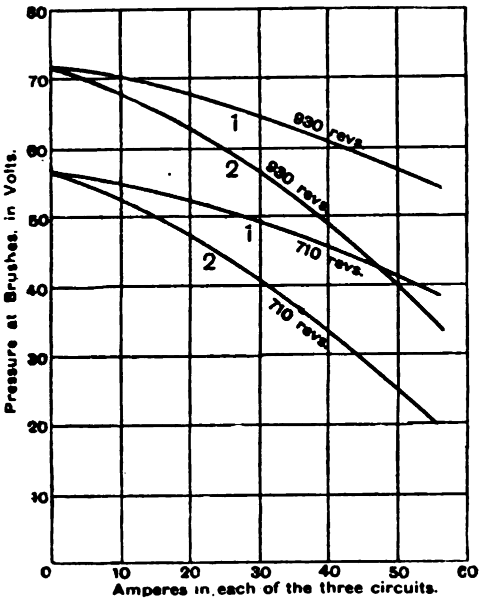

FIG. 18.—Fall of Pressure at Terminals of Drehstrom Dynamo with Armature Coils Coupled as in Fig. 17. Curves 1. Only One Circuit Loaded. Curves 2. All Three Circuits Equally Loaded.

In C a Prony brake was applied to the pulley of the motor, and in D and E a dynamo was driven, as in the tests of Groups A and B, this being found to be more convenient.

Group C.

No. of test.		Motor speed.		Pressure on mains.		Amperes in each circuit.		Weight on end of 24 in. brake arm.
1	......	736	......	84	......	31	......	2 lb.
2	......	624	......	82	......	32	......	3 lb.
3	......	500	......	83	......	32.9	......	4 lb.
4	......	500	......	81	......	33	......	4 lb.
5	......	340	......	84	......	34.7	......	5 lb.

The frequency was 16.

Groups D and E.

No. of test.		Motor speed.		Pressure on mains.		Amperes in each circuit.		Dynamo speed.
1	......	0	......	79	......	37.8	......	960
2	......	340	......	79	......	34.8	......	960
3	......	512	......	78	......	32.5	......	960
4	......	740	......	77.5	......	30.6	......	960
5	......	820	......	77.5	......	28.15	......	960
6	......	864	......	76	......	28.1	......	960
1	......	922	......	91	......	31	......	952
2	......	914	......	90	......	32.9	......	956
3	......	0	......	85	......	39.8	......	970

In both D and E the frequency was approximately 16.

Next, the dynamo speed was increased to 1,960 revolutions in Group F, and to 2,000 revolutions in Group G; and the motor connections were altered to the triangle or closed type. This required 1.732 times the current and 1 / 1.732 times the pressure for the same output with the star or open type connections (see the latter part of 5). The Prony brake was used in Group F.

Group F.

No. of tests.		Motor speed.		Pressure on mains.		Amperes in each circuit.		Weight on 24 in. brake arm.		B. H. P. of motor.
1	...	1,820	...	41.5	...	26.5	...	1	...	0.68
2	...	1,480	...	41	...	29.8	...	3	...	1.67
3	...	1,200	...	40.5	...	31	...	4	...	1.8

The frequency was 32.6.

Group G.

No. of test.		Motor speed.		Pressure on mains.		Amperes in each circuit.
1	....	0	....	36.5	....	39.4
2	....	732	....	37	....	35
3	....	1,000	....	37.75	....	35
4	.. ..	1,276	....	38.75	....	30.5
5	....	1,702	....	41.5	....	27
6	....	1,750	....	42.5		27 Motor running free.

The frequency was 33.3.

Groups A and B were made to see how far the excitation of the dynamo affected the experiments. The pressure on the main varies, of course, with the excitation, but the speed of the motor, as far as can be seen from these rough measurements, is nearly independent of the pressure, and seems rather to vary with the frequency and perhaps the lag. The law connecting speed and current variation for constant frequency and pressure of supply is not very obvious, and evidently requires the lag to be taken into account. For example, see Group B : In test 6 the motor loaded with 27.6 amperes in each circuit and 75 volts makes 866 revolutions; and test 7 shows zero speed for 75 volts and 34.7 amperes. Evidently the lag in 7 is far greater than that in 6. This is confirmed by test 1 in Group D, by test 3 in Group E, and test 1 in Group G. It is curious to notice how small are the variations of current between running light and full load, or even when the armature is held stationary. This large waste or idle current is most prejudicial, and if it cannot be lessened by some practical means (by condensers or otherwise) will militate seriously against multiphase motors without commutators. If the revolving part of the motor be supplied with the triphase current, these troubles will be much less, because the moving parts will contain less iron, and hence the hysteresis and eddy current losses, and the induction disturbances will be of less importance. The frequency in the induced circuit is then so small as to give little trouble.

In Group C a Prony brake with a lever 2 feet long was fitted around a 16 inch pulley, and the motor was supplied with current of 16 ∼ per second. The pressure and current variations are seen to be insignificant, though the speed varies some 50 per cent. This low frequency (16) was found unsuitable for the design of the motor, since it gave too low a speed; but the tests in Groups D and E were taken so as to show the capabilities of the motor under these conditions. The power of the motor was utilized to drive a direct current dynamo, the two machines being coupled by a belt. The figures in Group D again show large variations of speed for nearly constant pressure and small changes of current. In Group E the pressure was increased, but only a few readings were taken, as the increase in speed was insufficient to give results widely different from those obtained in the preceding tests.

In the next experiments the connections of the motor were altered to the triangle or closed arrangement, the end in view being the increase of motor speed and consequent output.

The tests in Group F are some of the most important in the series, for the output measured by the Prony brake was sufficiently large to give practical data. It will be seen that the frequency was 32.6 per second and the pressure about 41 volts. The speed again shows large variations. When running light the speed of synchronism, 1,960 revolutions, was nearly attained.

In Group G the motor was coupled to a small dynamo by a belt, and the frequency was raised to 33.3 per second. In test 6 the motor was running free, but the speed was 250 revolutions below that of synchronism. The best results seem to have been obtained with a frequency of about 32 (test 3, Group F), and it appears probable that if the arrangements had been such as to admit of a larger current at this frequency, at least 3 B. H. P. might have been taken from the motor.

These rough experiments show the importance of reducing the magnetizing current to a minimum. It can be accomplished by careful attention to the design and by making the air-gap as small as possible. The Drehstrom motor may be regarded as an open magnetic circuit transformer, and the only way to lessen the waste current is to make the magnetic resistance as low as possible. Mr. C. E. Brown has already suggested bedding the field as well as the armature turns in iron, and the same end may be attained by perhaps a better way, i. e., by winding the field coils in drum fashion.

7. DREHSTROM MOTORS WITH STATIONARY ARMATURES.

Triphase motors are sometimes made with the rotary magnetic field in the revolving part of the machine. This necessitates brushes and rings, it is true, and consequently simplicity of design is departed from, but it must be recollected that there can be no sparking under ordinary conditions. The brushes would probably be made of flexible strands of copper, such as are commonly used for alternators. The chief point gained is that the most marked effects of hysteresis, eddy currents, and self-induction are limited to the relatively small moving part of the machine, whilst the massive stationary portions, which then form the armature, are magnetized by currents of frequency equal only to the difference between the speed of the armature and that of the rotary field. It is clear that the speed of the revolving part can never equal that of the rotary field; but at normal loads the period of the armature current will be small, and therefore the heating from hysteresis, etc., will be comparable with that of a direct-current machine, the period probably being of the order of from eight to ten per second. Herr Dobrowolski's 2 H. P. motor is of this type, and a brief comparison with the small motor built by the author may be interesting, because it will show the order of the results obtained from the two types of machines. Herr Dobrowolski's motor weighed approximately 365 lbs. and the maximum output deemed advisable was 4 B. H. P. at about 1,700 revolutions per minute. On open circuit it made 2,100 revolutions, and at 2 B. H. P., the rated output, about 1,950. The frequency was 35, the supply pressure 70 volts, and the torque at starting considerable. The lag was stated to be 72 deg. when the motor was running light, 28 deg. at 2 H. P. and 22 deg. at 3 H. P. The efficiency at 1 H. P. was 75 per cent., at 2 H. P., the rated output, it had reached to about 80 per cent., and at 2.3 H. P. it attained its maximum of 81.4 per cent. The author's motor weighed about 300 lbs., and at 1,200 revolutions gave 1.8 H. P. on the brake, and it was evident from the slight heating that this output could have been safely doubled if the speed had been raised to about 1,800 revolutions, but it had a larger lag than the other machine, the waste currents at small loads were much greater, and the all-round efficiency was certainly less.

8. COMBINED ROTARY AND SYNCHRONOUS MOTORS.

A multiphase dynamo requires the revolving field magnets to be separately excited by a direct current. It is reversible, and will run as a motor if supplied with a multiphase current, but is not necessarily self-starting, and probably will not start against a large torque. If, however, the magnets be rotated so as to synchronize with the rotary magnetic field, the motor will work as satisfactorily as a single-phase machine.

Attempts have been made to combine the advantages of a self-exciting rotary field and a synchronous motor. The plan proposed is some modification of the following idea: The moving part, usually the armature, is wound with two circuits, the one closed on itself acting precisely as the closed circuits of the multiphase armature, the second supplied with a direct current and therefore having fixed poles. When the field is excited by a rotary current the induced currents in the closed circuits will start the armature (if the torque be not too great) and the permanent poles due to the direct current will have but little influence. But as the speed of synchronism is approached the induced currents in the armature will decrease, and the fixed poles will have more effect, until finally the armature rotation will be entirely due to them.

Such a motor has many disadvantages, besides requiring an independent direct current. It necessarily has a low efficiency at starting and at all speeds below that of synchronism; but within wide limits of load when once started it will run at a constant speed with a high efficiency.

The initial torque cannot be so great as that of a simple diphase or Drehstrom winding, since the closed circuits on which the starting depends are relatively smaller.

Mr. Schuckert has built a self-exciting diphase rotary-field synchronous motor on the above principles. But the method does not appear to offer any special advantages, and it is not likely that such motors will supersede ordinary single-phase alternators.

9. SINGLE-PHASE NON-SYNCHRONOUS MOTORS—SELF-EXCITING AND SELF-STARTING.

Messrs. Hutin and Leblanc, C. E. L. Brown, and others have devised modified forms of Prof. Elihu Thomson's motor, all of which will run with single-phase currents, non-synchronously and with good efficiency.

The principle seems to depend on the induction of currents in short-circuited coils, in unsymmetrical positions with reference to the main field, but this end is not necessarily attained by brushes and rings, as in Thomson's motor, but by the rotation of the armature itself. In its simplest form this type of motor has no commutator, and is self-exciting, but will not start. If, however, the armature be spun in either direction, it will rapidly acquire the speed corresponding to the torque, and will then revolve at a uniform rate.

By the combination of an additional rotary magnetic field, the armature can be made to start against a considerable torque, and the auxiliary field can be stopped after the proper speed is attained. Various devices to secure such a field are suggested by Mr. C. E. L. Brown, the most feasible being two parallel windings on the field magnets, one with small self-induction (or even capacity), and the other with larger self-induction. These two circuits when supplied with a ngle-phase current will produce a rotary field, and so cause the armature to revolve. (Other forms of this ingenious motor have been suggested by Mr. Brown, for which reference should be made to the technical journals of March of this year. Most of the arrangements, however, necessitate rings and brushes, and the motor is therefore only preferable to a synchronous reversed dynamo inasmuch as it is self-exciting and self-starting. These two points are of great importance with small motors, and probably the invention will be of utility in many ways.)

The general details of construction are, broadly, similar to those of a multiphase motor, but the number of poles in the field magnets and armature must not have a common factor, and the windings of both armature and field magnets are preferably laid in grooves or holes in the iron, an arrangement which permits the magnetic resistance to be reduced to a minimum and decreases losses from Foucault currents, while the weight output is increased. This is perhaps the best type of single-phase motor up to date, but it is undoubtedly susceptible of considerable improvement, and the problem of alternate-current motors suitable for running or ordinary supply circuits cannot yet be said to be satisfactorily solved.

(Concluded.)

At a meeting of the laryngological section of the Academy of Medicine, recently, Dr. Wendell Phillips exhibited what he called an electric head illuminator. A small boy was taken from the audience, and a powerful electric lamp was inserted in his mouth, which was then closed on the handle which held the lamp. The lights of the hall were turned down, and the storage battery turned on. The light in the boy's mouth shone out through his cheeks, detailing every vein, line or imperfection in the skin and gums in the mouth.

Boston Notes.

By September 1 the cities of Lowell, Lawrence and Haverhill, three of the most prosperous cities in Massachusetts, will be connected one with the other by an electric railway under a single management. This fact is expected to give the above cities a tremendous boom, and far-seeing citizens are making predictions on the future development of the three cities.

The trouble at the Lynn factories of the General Electric Company is practically over. Last Saturday the company made a proposition to the men conceding 56 hours work and 58 hours pay per week, which has been practically accepted.

The eyes of the entire country are being turned towards Boston these days, where changes, developments and improvements are being introduced by the electrical workers, and it is no exaggeration to state that within the next two or three weeks several new devices of an electrical character will be presented for popular favor and acceptance by Boston electricians that will mark entirely new departures in this great field of commercial industry.

The Union Railroad Company, Providence, R. I., has secured from the Legislature power to absorb every electric and horse railway in the State. This is the only instance that we know of where a single corporation enjoys such power and authority for an entire State.

The State of Maine is as enterprising as any State in the Union in the matter of electric lights and electric railways. Several light and power stations are at present underway, and it looks as if Bangor and Oldtown would soon be connected by electric railway.

So great is becoming the demand on the Edison Electric Illuminating Company of Boston that they find it necessary to extend their underground wires right along. No sooner is one section of the city equipped than the demand for more light and power comes from another, so that a very large staff of men is constantly employed on underground work solely.

The entire fleet of Nantasket Beach steamers are now equipped with electricity. The United States system has been installed, the New England Weston Company having been the contractors, and the work throughout, including the handsome fixtures, has been done in first class shape.

The Rapid Transit question for Boston drags its slow length along before the Legislature still. There does not appear much prospect of the problem being tackled without gloves for some time to come, and so the patient and long-suffering public has to wait until the State Solons can decide just what the solution of the problem is to be. Some very hard things, approaching nearly to "cuss words," have been bandied about in the legislative halls and corridors lately, but the arriving at a useful decision seems remote yet.

Chicago Notes.

Mr. Thos. L. Townsend, representing Partrick & Carter, of Philadelphia, was a Chicago visitor last week. He took in the Fair, and made the acquaintance of a number of the exhibitors.

H. L. Blizzard, manager of the Franklin Electric Company of New York, put in the greater part of last week in Chicago and at the World's Fair.

C. A. Daigh, until recently the Chicago representative of the National Electric Company, and formerly the manager of the same company, has accepted the position of selling agent for the Siemens & Halske Electric Company.

The friends of Wm. F. Taylor, of the firm of Taylor, Goodhue & Ames, are sympathizing with him in the loss of his daughter, her death occurring last week after a short illness.

The Chicago Athenæum has made arrangements to give a series of lectures twice a week in one of the halls of the building on the "Science of Electricity" as illustrated in the Electricity Building at the World's Fair. Following each lecture the members attending will be conducted through the building, and exhibits explained by one of the lecturers.

General News.

What is Going on in the Electrical World.

Jersey City, N J.—The annual meeting of the Cataract Construction Company (Niagara Falls), will take place here on June 8.

St. Augustine, Fla.—The Ponce de Leon Hotel is being rewired for a change in its electric lighting which it is said will cost $60,000.

Pittsburg, Pa.—C. I. McDonald & Company have been awarded the contract for building the Pittsburg, Neville Island and Coraopolis electric road.

Frederick, Md.—The Frederick and Middletown Valley Railroad has been granted a franchise for an electric railway in specified streets in Frederick.

Harrisburg, Pa.—The session of the Legislature ended on the 1st inst. The bill giving increased powers to electric railway companies failed to pass.

Glens Falls, N. Y.—The stockholders of the Glens Falls Electric Street Railway intend to increase the capital stock of the company from $30,000 to $120,000.

Chattanooga, Tenn.—The Alton Park Land Company is going to build an electric railroad from this city to Alton Park. Engineers are at work on the survey.

Newport, R. I.—H. N. Hassard has received permission from the committee on street lights to place a number of electric lights along Eastin's Beach, beginning at the Cliff walk.

Tiffin, Ohio.—Work has begun on the Tiffin and Fostoria Electric Railway, and a large force of hands will be kept on it until it is completed. The road will be fourteen miles long.

Huntington, L. I.—The town board has granted a franchise to the Huntington Electric Light, Heat and Power Company for lighting election districts 1, 2 and 3 of the town.

Maumee, Ohio.—A franchise has been granted to Albion E. Lang, representing the Toledo Consolidated Street Railway Company, to build an electric railway from Toledo to Maumee.

Sedalia, Mo.—It is learned that the Missouri, Kansas and Texas Railroad Company will at an early date commence the construction of a telephone line from St. Louis to Parsons, Kans., a distance of 348 miles.

Hamilton, Can.—The Hamilton Radial Electric Railway Company will in October supply all the power required in Hamilton for every purpose, bringing it from Niagara Falls at an estimated cost of $200,000.

Manchester, N. H.—The new contract between the city and the Electric Light Company for lighting the city streets is for ten years and will result in a saving of $60,000 as compared with the former contract price.

Detroit, Mich.—A franchise has been granted to Parke, Davis & Company to do commercial electric lighting in the district adjacent to their factory, on the condition that they pay an annual tax amounting to $31 per mile of wire laid.

Digby, N. S.—Bear River is to have electric light, the generating power to be supplied by the falls on the west branch of the river.—The Annapolis Valley Telephone Company have put in a branch from Granville Ferry to Belleisle.

Syracuse, N. Y.—The Syracuse Telephone Company has applied to the council for a franchise to do a telephone business, offering much lower rates than the present. Wm. Cowie is the promoter of the company, which is not yet incorporated.

Peekskill, N. Y.—The Peekskill Electric Surface Railway Company have decided to build the road themselves, considering bids offered for the construction work to be too high. Work will be pushed so as to complete the road as soon as possible.

Salt Lake, Utah.—The mayor's veto of the twenty-five year franchise recently granted by a vote of council to the Salt Lake and Ogden Gas and Electric Light Company although at first sustained was on reconsideration of the vote by council not agreed to and the franchise stands.

London, Can.—The Canadian General Electric Company have bought out Hunt Bros.' electric lighting and power business, and will make it the nucleus of their new plant and business in this city. They have appointed Charles B. Hunt local manager, and he will take full charge.

Elizabeth, N. J.—A charter for a new electric railway is being prepared. The road is to run up Morris avenue through Springfield and thence probably to Summit. The name of the road will be the Ursino Park and Springfield Electric Railway, and Silas D. Drake is its chief promoter.

Pittsfield, Mass.—A controlling interest in the Pittsfield Electric Railway has been bought by Dolan Bros., of New Britain, Conn. The new owners are said to be desirous of extending the railway to Dalton this year, and will do so if such action meets the approval of the Pittsfield directors.

Trenton, N. J.—It is understood that a syndicate has under consideration plans for an electric belt line for this city. The talked-of line takes in the Interstate Fair, Battle Monument, Cadwalader Park, Riverview Cemetery, Broad Street Park, Greenwood Cemetery, and back to the fair grounds, circling the entire city.

Bucyrus, Ohio.—The right of way has been obtained for an electric railway from Galion to Bucyrus. It will be twelve miles long and go through a country thickly settled with prosperous farmers. There is also under contemplation the building of a line eighteen miles long from New Washington, through Sulphur Springs, to Bucyrus.

Battle Creek, Mich.—The electric street car line in this city has changed management, W. J. Willson, the former superintendent and general manager, having been superseded by A. K. McRae, of Chicago, who purchased his stock and assumed his place. Ex-Governor John L. Beveridge, of Illinois, is the principal stockholder in the company.

Montgomery, Ala.—The sale of the Cloverdale electric railway by order of the court may lead to a consolidation of the Cloverdale line and the Montgomery Terminal Street Railway, a scheme which is now under consideration. If the consolidation takes place electricity will be extended over both lines. The new organization will have a capital stock of $350,000.

Peoria, Ill.—The Fort Clark Electric Railway has changed hands, the General Electric Company having gained possession of it. The new directors are F. O. Cunningham, W. T. Whiting, of Peoria; G. H. Atkins, J. S. Cummins, F. W. Horne and Theodore P. Baily, all of Chicago. B. K. Otis, of Peoria, was chosen secretary and treasurer to succeed Willis Hall.

Bangor, Me.—An electric railway to connect Bangor with Hampden, Winterport, Frankfort, Prospect and Stockton Springs has been planned, and will probably be built Among those interested in the scheme are Gen. H. L. Mitchell and E. C. Nichols, of Bangor; H. W. Mayo, of Hampden; Fred Atwood, of Winterport; J. Manchester Haynes and George E. Macomber, of Augusta, and H. L. Shepherd, of Rockport.

Cleveland, Ohio. — The Cleveland General Electric Company, lately formed by a combination of the Cleveland Electric Light Company and the Brush Electric Light and Power Cempany, intends to erect a power station in the downtown district and equip it with the latest and most improved machinery, with cables running all through the city to furnish light, heat and power. The estimated cost is about $600,000.

Newark, N. J.—The Central Power Company, which secured possession of valuable city franchises for the distribution of power by purchase of the Schuyler Company's interest, has determined to increase its capital stock from $50,000 to $100,000, and will proceed at once to develop the business of supplying electric power throughout the city. Among the men interested in the company are A. Q. Keasley and W. H. Lemassena.

Middletown, Ohio.—C. F. Gunckle, a prominent banker here, has purchased G. N. Clapp's controlling interest in the Electric Light and Gas Company. The electric light plant will be enlarged and power furnished for street car and other purposes.—There is a movement on foot by prominent capitalists of Middletown to put electric boats on the Miami and Erie Canal, which connects Toledo and Cincinnati.

West Buxton, Me.—Mr. R. S. Brown, of the Westinghouse Electric and Manufacturing Company, has been in consultation lately with a number of our citizens who are anxious to have an electric railway from Bar Mills to Bonney Eagle by the way of West Buxton. There is a magnificent water power at Bonney Eagle that might be utilized in the generation of power. The road will probably be built.

Niagara Falls, N. Y.—At a meeting of the stockholders of the Niagara Power Company held here on the 1st inst. the following directors were elected: C. B. Gaskell, Benjamin Flagler, W. C. Ely, Peter A. Porter, De Lancey Rankine, A. J. Porter, L. W. Pettibone, F. A. Dudley, of Niagara Falls, and Dr. Coleman Sellers, of Philadelphia. The board elected the following officers: President and chief engineer, Dr. Coleman Sellers (who will move here from Philadelphia); vice-president, Benjamin Flagler; treasurer, De Lancey Rankine; secretary, James S. Milner.

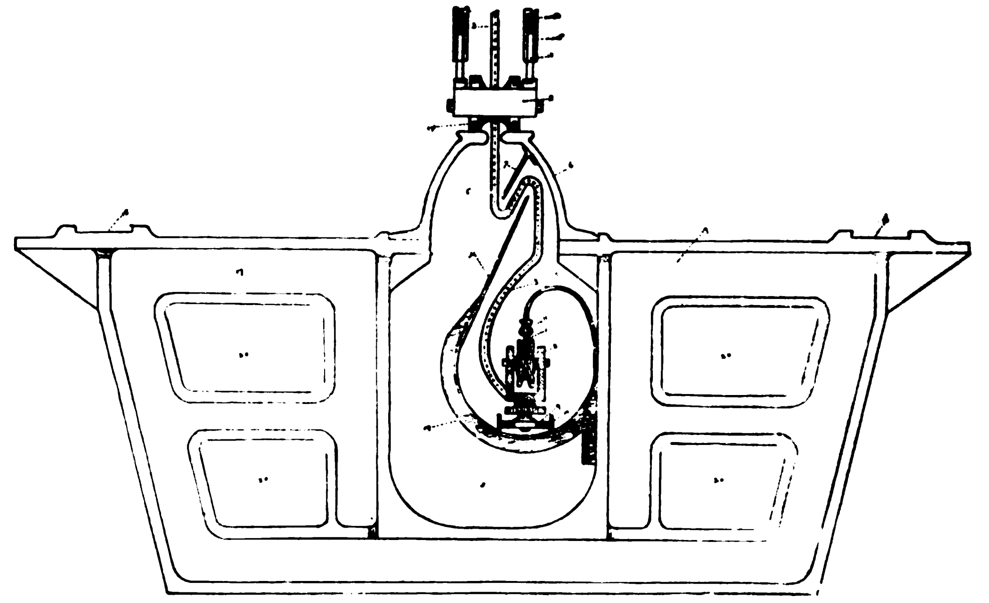
Hartford, Conn.—The special committee on street railroad improvements recommend a trial of the storage battery system on the Hartford and Wethersfield road, and this failing, the trolley system is their next choice. The Milford storage battery system is favored in the committee's report, but Dr. Robb, of Trinity College, Hartford, while calling attention to the suit of the Brush Electric Company against the Milford Company for infringement of their battery patents, considers the Milford system inapplicable to the Hartford line on account of the heavier grades that would be encountered as compared with those on the Milford and Hopedale road.

Noblesville, Ind. — The city council has granted a thirty years franchise to the Chicago Electric Street Railroad Company to put down tracks in this city. It is thought that Noblesville will be made the focal point of a network of railways extending over the entire Indiana gas belt, and connecting with Indianapolis.--A dispatch from Noblesville, received at Indianapolis June 2, says: "Last night an organization known as the 'Central Indiana Electric Railway Company' was perfected with a capital stock of $4,500,000. It is composed of moneyed and influential men from Dayton, St. Louis, Chicago, Philadelphia and London, England. The purpose of the new organization is to connect Indianapolis, Noblesville, Anderson, Muncie, Elwood, Tipton, Kokomo, Frankfort, Peru, Logansport, Lafayette, Marion and Fort Wayne by electric street car lines."

Washington, D. C.—Engineers have lately been engaged in marking the proposed route of the Washington and Great Falls Electric Railroad. It is the intention to run a double track line as far as Cabin John Bridge at first, and if the business demands it the tracks will be laid to Great Falls. The road will begin at the north end of the Aqueduct Bridge and be elevated twenty feet on steel pillars. The elevated track will be twenty-four feet wide, covering the entire canal road. It has not been definitely settled as yet whether a trolley or motor system will be used, but in all probability the latter system will be adopted. The power at first will probably be supplied by the Potomac Electric Light Company, the works of which are at the Virginia end of the Chain Bridge. The present officers of the company are: President, J. H. Rotherbut; vice-president, George S. Chase; treasurer, John G. Slater; secretary, Col. Tyree; board of directors, Smith Pettit, John G. Slater, J. R. Robbins, C. A. Maxwell, J. H. Rotherbut, George Chase and W. C. Codd.

Conduit Railway System.

Although some of the matter written on the "deadly trolley" is exaggerated, still electrical railroad men, as a rule, look to the future with the hope of seeing brought out a more perfected electrical railway system that shall do away with the many objections and dangers incidental to overhead trolley for street use. As to the outcome of just what line of improvement the ideal system of the future will be, it is at the present time impossible to say.



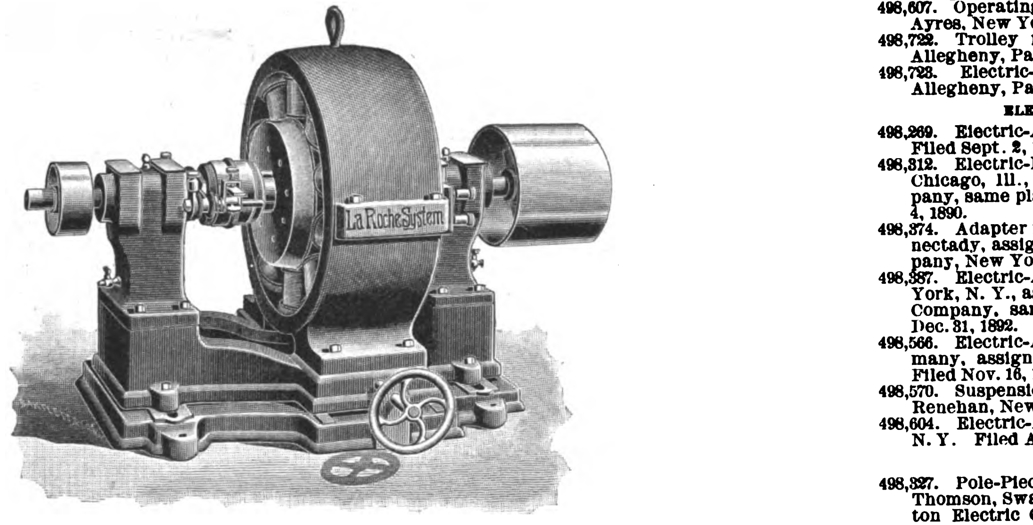
CONDUIT RAILWAY SYSTEM.

Conduit and storage battery systems both seem to be in the line of progress, with, perhaps, the advantage at present with the former. If we only had perfectly clean streets, no floods, snows, and obliging and progressive municipal governments, the conduit system would become very popular at once. While it is true that these conditions are not with us to any great extent, it is also true that by the ingenuity of inventors conduit systems are being brought forth which are surmounting the many obstacles in the path and making the conduit system a reliable and efficient one.

Our illustration shows a recently invented conduit system which has many points of merit and overcomes many of the objections hitherto brought forward. Some electrical conduit systems have been practically inoperative on account of the arcing of the current from the electrical conductor to surrounding parts, caused by the insulation used not being adequate to prevent it; and also on account of the drip from the slot rail opening and consequent flooding of the conduit, while in many others the numerous mechanical parts often get out of order. In the accompanying illustration of the system is shown a cross-section with yoke (17), as in cable road construction, which supports the conduit (5) and slot-rails (6). The chamber in which the conductor (No. 1) is placed is, by the overlapping cover (No. 7) protected from floods until the water rises to within six inches of the street level. By the form of the trolley arm it becomes impossible for rain to drip into the conductor tube. Dirt or water falling through the street slot is prevented by the cover (No. 7) from entering the tube which contains the electrical conductor, etc., and is gathered at the bottom of the large chamber. Ample air insulation is given by the conductor being placed centrally in the trolley chamber. The lateral and perpendicular motions of the trolley arm are provided for by the guide carriage and the point of contact of the trolley wheel on the trolley may be at the top or bottom of it. This promising system is brought out by the Electrical Conduit Traction Equipment Company, 94 Wall street, New York City.

La Roche New Alternating Dynamo.

The cut herewith represents one of the types of alternating machines built by the well-known La Roche Electric Works of Philadelphia. The above company was one of the first in America making a specialty of alternating apparatus. The demand for their alternating machines has been so great that they were compelled to make up a full line of small alternators, and now build same with a frequency of 16,000 revolutions, and from 25 to 3,000 lights. The La Roche machines are well known throughout the United States and Europe. The company has been very successful with these machines which are made in two classes—self-exciting and non-exciting.



La Roche New Alternating Dynamo.

The machines from 25 lights up to 500 lights are arranged with ten poles, running at 1,600 revolutions, thereby giving a frequency of 16,000 per minute. The larger machines, of course, have more poles and give the same frequency, but at a lower speed. The alternators have all modern improvements, with all parts interchangeable and made to gauge; they have been designed by Mr. F. A. La Roche. They have self-oiling bearings and an automatic oil overflow. The brushholders are of a new design and so made that any degree of tension can be secured. The machine, of course, has no commutator, but has two collector rings which are made of specially hardened copper well insulated with mica. The fields in even the smaller machines are made separable so that any repair work can be done without interfering with balance of the machine.

The field bobbins are separately wound and slipped over the core, and any of them can be replaced, in case of necessity, in a very few minutes.

The armature is built up of the best laminated, pure charcoal iron, well magnetically insulated. The core is mounted on two of the La Roche latest bronze spiders well secured to polished steel shaft. The shaft is turned down to standard size where entering bearings. The armature coils are separately wound, and any intelligent person can replace any or all in a very few minutes as this company has a new method of securing the coils to the core. They also have a new and improved method of connecting and winding the armature whereby the difference of potential between coils never exceeds 200 volts, while in machines of other systems now in use the difference of potential between coils is from 500 to 1,000 volts. By the La Roche system it is almost an impossibility to have a burnout or short-circuit from lightning. The coils are insulated from the core of the armature by the best grade of mica that can be procured. It will be noticed that the above cut is not of the self-exciting type, neither is the exciter attached to this illustration.

At a test of some of these machines it was found that there was a variation of only 2 3-10 volts between no load and full load, which is a sufficiently close regulation for any alternating machine.

This company has placed alternators with such well-known concerns as the University of Wisconsin; Messrs. Queen & Co., Philadelphia; Helios Electric Company, Philadelphia, etc., and they can show flattering testimonials from all parties using their system.

All the machines have a cast-iron sub-base well secured and mounted so that no foundation is required, as the sub-base answers that purpose.

COMMERCIAL PARAGRAPHS.

Some good contracts have recently been secured by Boston electrical supply houses. Among these may be mentioned the Brown Electric Company, which has closed contract for the equipment of the South Jersey Traction Company's road, which will be thirty-six miles in length, connecting a number of small towns in central New Jersey.

The firm of Cummer, Craig & Company, Boston, has the contract for equipping the new building of the Boston Plate and Window Glass Company with a 600-light plant. A Crocker-Wheeler dynamo will be installed. This electrical firm now represents the Crocker-Wheeler, Bishop Gutta Percha, Waddell-Entz, General Incandescent Arc Light, Star Electric Lamp and Interior Telephone Companies.

The Hawks Electric Company, Summer Street, Boston, reports a constant increase in its business, having many nice contracts in hand and several additional ones coming along. Altogether the outlook for the electrical business is very promising, notwithstanding this is the time of the year when a big rush is not looked for.

No better evidence of the standing and sterling features of the Ansonia Electric Company's specialties could be had than from the number of propositions that are being made them by foreign companies through their representatives who are visiting the Fair, they appreciating in particular the value of the Wirt Indicators, Wirt Brushes and W.-W. Lightning Arresters, of which the Ansonia Electric Company are sole manufacturers.

Very large sales of Habirshaw wire during the past week have been reported to us as having been made by the Ansonia Electric Company, formerly the Electrical Supply Company.

The good work done by the Wirt Brush in saving commutators seems to be appreciated by the customers of the Ansonia Electric Company (formerly the Electrical Supply Company), judging from the growth of the sale of the brush.

INCORPORATIONS.

The Poudre Valley Telephone Company, Greeley, Col. Capital stock, $5,000. Directors: H. C. Watson, A. S. Eaton, Harrison Teller, Willus H. Eaton and James S. Newell. The company will operate lines from Greeley to Eaton and from Greeley to New Windsor, Fort Collins and North Poudre canon. The object of the company is to assist the irrigating system of Poudre Valley and not for personal profit.

The Fort Smith and Van Buren Electric Light and Power Company, Fort Smith, Ark. Capital stock, $100,000. Incorporators: W. C. Lemert, Jas. B. Gounly, Miles N. Beaty, A. F. Howard, Wm. Blair, F. T. McClure and R. C. McClure. The company propose to conduct, maintain and operate an electric street railway from Fort Smith to Van Buren, and to purchase or consolidate with other street railway companies in either or both of said cities, and to maintain and operate the same; and also the production, generation and furnishing of light, heat and power.

The College Hill Electric Railway Company of Cincinnati. Capital stock, $10,000. Incorporators: Peter G. Thompson, Lowe Emerson, Adam G. Gray, Newbold I. Pierson and Samuel A. Ramp.

United States Automatic Telephone Register Company, Chicago. Capital stock, $100,000. Incorporators: Sylvanus Hemans, William B. Thompson, Frank P. Blair.

The Mason Electric Company of New York City—to manufacture and deal in electrical goods in New York City and Brooklyn. Capital $25,000. Directors: Albert Van Derwerken, James H. Mason, Albert Van Derwerken, Jr., and Frank B. Johnson, of Brooklyn.

The Garton-Daniels Electric Company, Keokuk, Iowa—to manufacture the Garton lightning arrester and other electrical machinery and appliances. Capital stock, $20,000. Incorporators: W. R. Garton and J. C. Daniels.

Bar Harbor Electric Light Company, Portland, Me.—to supply light, heat and power by gas or electricity. Capital stock, $75,000. President, Geo. F. West, of Portland; treasurer, Luther A. Leach.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MAY 30, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

498,403. Electric-Railway Trolley. Patrick F. O'Shaughnessy, New York, N. Y., assignor to the Sprague Electric Railway and Motor Company, same place. Filed Sept. 27, 1888.

498,435. Electric-Railway Trolley. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Original application filed June 7, 1888. Divided and application filed Nov. 8, 1888. Again divided and this application filed March 4, 1892.

498,577. Electric Locomotive. Albert Schmid, Allegheny, assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Filed Nov. 16, 1891.

498,603. System of Supplying Currents to Electric Railways. Charles Zipernowsky, Buda-Pesth, Austria-Hungary. Filed March 7, 1891.

498,607. Operating Street or Station Indicators. Ruben B. Ayres, New York, N. Y. Filed Dec. 22, 1891.

498,722. Trolley for Electric Cars. Robert D. Nuttall, Allegheny, Pa. Filed July 14, 1891.

498,723. Electric-Railway Trolley. Robert D. Nuttall, Allegheny, Pa. Filed May 10, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

498,269. Electric-Arc Lamp. Louis Hills, New York, N. Y. Filed Sept. 2, 1891.

498,312. Electric-Lighting System. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed June 1, 1889. Renewed Nov. 4, 1890.

498,374. Adapter for Lamp-Sockets. Henry P. Ball, Schenectady, assignor to the Edison General Electric Company, New York, N. Y. Filed July 6, 1892.

498,387. Electric-Arc Lamp. Frederick D'A. Goold, New York, N. Y., assignor to the Edison General Electric Company, same place. Filed Nov. 7, 1891. Renewed Dec. 31, 1892.

498,566. Electric-Arc Lamp. Paul Nordmann, Berlin, Germany, assignor to Siemens & Halske, same place. Filed Nov. 16, 1892.

498,570. Suspension Device for Electric Lamps. James J. Renehan, New Britain, Conn. Filed Sept. 29, 1892.

498,604. Electric-Arc Lamp. Hugh Alexander, Brooklyn, N. Y. Filed April 19, 1890. Renewed Nov. 4, 1892.

DYNAMOS AND MOTORS.

498,327. Pole-Piece for Dynamo-Electric Machines. Elihu Thomson, Swampscott, assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Aug. 26, 1892.

498,462. Electric Rotary Fan. Julian F. Denison, New Haven, Conn., assignor to the Backus Water Motor Company, Newark, N. J. Filed March 15, 1892.

498,537. Dynamo-Electric Machine. Charles E. Dressler, New York, N. Y. Filed Oct. 6, 1891.

498,538. Electric Generator or Motor. Charles E. Dressler, New York, N. Y. Filed Sept. 15, 1892.

498,585. Electrical Rotary Motor. William J. Still, Toronto, Canada. Filed Dec. 28, 1891.

BATTERIES.

498,422. Galvanic Battery. William Burnley, North East, Pa. Filed June 15, 1892.

498,743. Galvanic Battery and Electrical Toy Instrument. William A. Connelly, Boston, Mass., assignor to the Electro-Novelty Company, Portland, Me. Filed Sept. 1, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

498,236. Telephone System. Emery A. Clark, Sioux City, Iowa, assignor, by direct and mesne assignments, to the Clark Automatic Telephone Equipment Company, same place. Filed April 5, 1892.

498,243. Telephone-Switch. Augustus G. Davis, Baltimore, Md. Filed Nov. 25, 1892.

498,291. Automatic Telephone-Exchange System. Alfred S. McCaskey, Chicago, Ill. Filed Aug. 25, 1892.

498,309. Telephone Transmitter. Charles F. Scattergood, Albany, N. Y. Filed Dec. 14, 1892.

498,503. Index for Telephones. Frank S. Blanchard, Worcester, Mass. Filed Oct. 10, 1892.

498,529. Printing-Telegraph. Edward V. Baillard, New Utrecht, N. Y. Filed Feb. 4, 1893.

498,674. Printing-Telegraph. Donald Murray, Sydney, New South Wales. Filed Nov. 2, 1892.

MISCELLANEOUS.

498,289. Electrical Signaling System. Alfred S. McCaskey, Chicago, Ill. Filed July 29, 1892.

498,290. Railway Block-Signaling System. Alfred S. McCaskey, Chicago, Ill. Filed July 29, 1892.

498,372. Electric Registering Device. Barton B. Ward, New York, N. Y. Filed May 28, 1890.

498,407. Insulated Binding-Post. Richard H. Rich, Beverly, Mass. Filed July 15, 1892.

498,448. Fire-Alarm System. Joseph Sachs, New York, N. Y. Filed June 24, 1892.

498,468. Electric Alarm-Clock. William M. Fowler, Milford, Conn. Filed May 6, 1892.

498,492. Gas Lighting or Extinguishing Apparatus. James Sangster, Buffalo, N. Y. Filed Dec. 27, 1892.

498,519. Electric Perforating-Pen. Aaron D. Lewis, Canton, Mo., and Silas Witherell, Fort Madison, Iowa; said Witherell assignor to said Lewis. Filed April 23, 1892.

498,560. Electric Cut-Out. William P. Mashinter, Montreal, Canada, assignor of two-thirds to Herbert Montague Linnell and Charles Morton, same place. Filed July 5, 1892.

498,624. Electric Car-Brake. Nicholas J. Clute, Schenectady, N. Y. Filed Oct. 24, 1892.

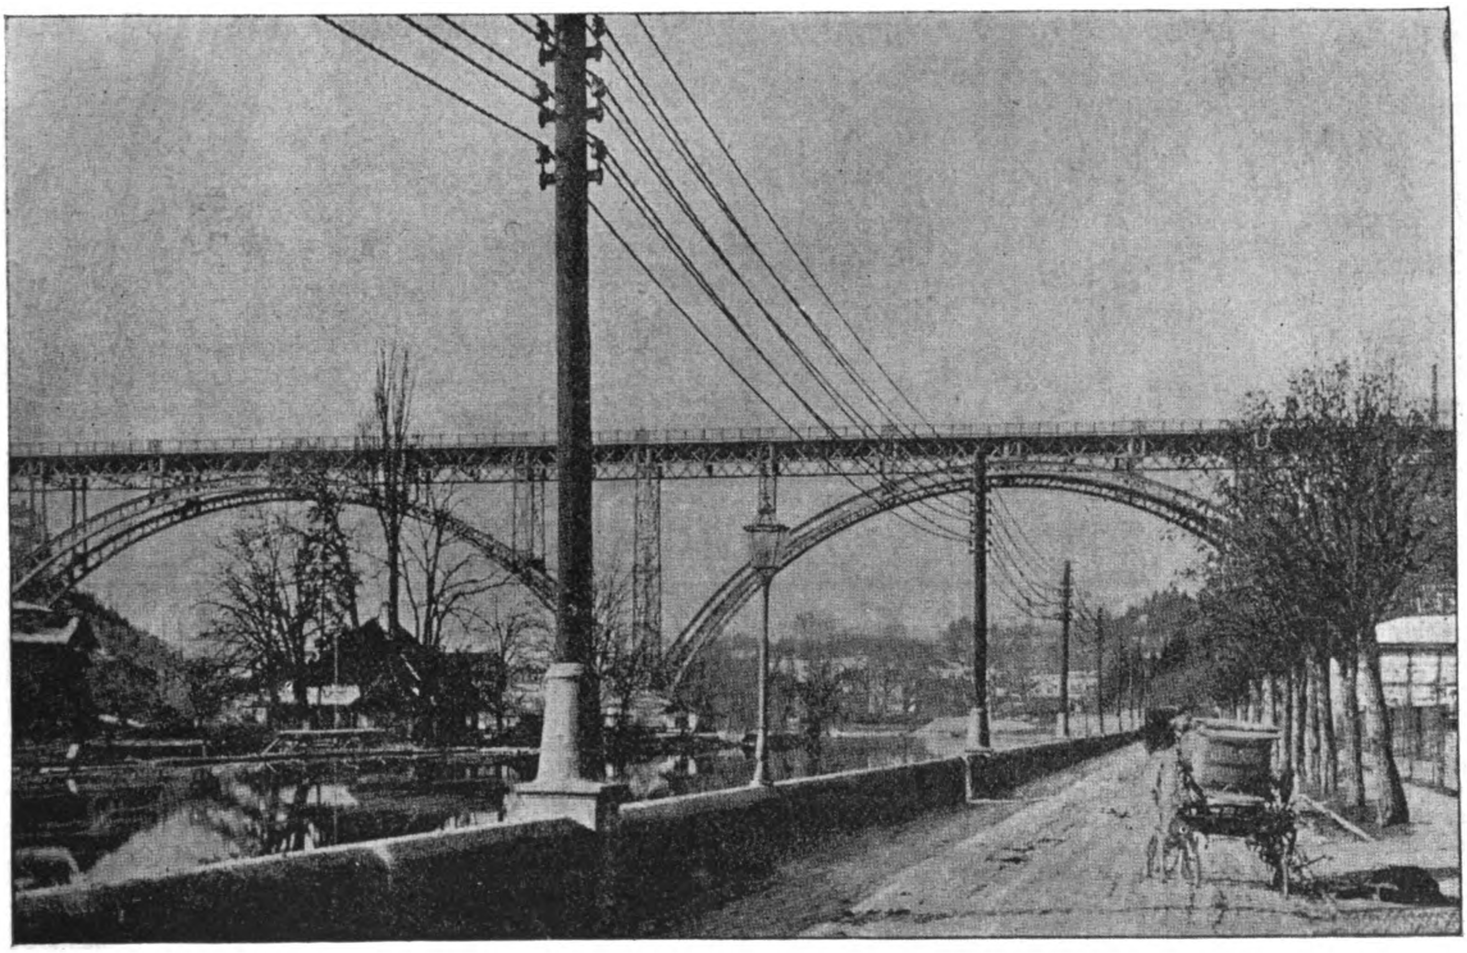
498,707. Copper-Coating the Hulls of Vessels. Thomas S. Crane, East Orange, N. J. Filed Oct. 12, 1892.

498,710. Electric Time-Alarm. Charles S. Gibson, South New Berlin, N. Y. Filed Oct. 12, 1892.

498,735. Electric Welding Apparatus. John H. Bassler, Myerstown, Pa. Filed Aug. 23, 1892.

ELECTRICITY.

VOL. IV. NEW YORK. JUNE 14, 1893. CHICAGO. No. 22

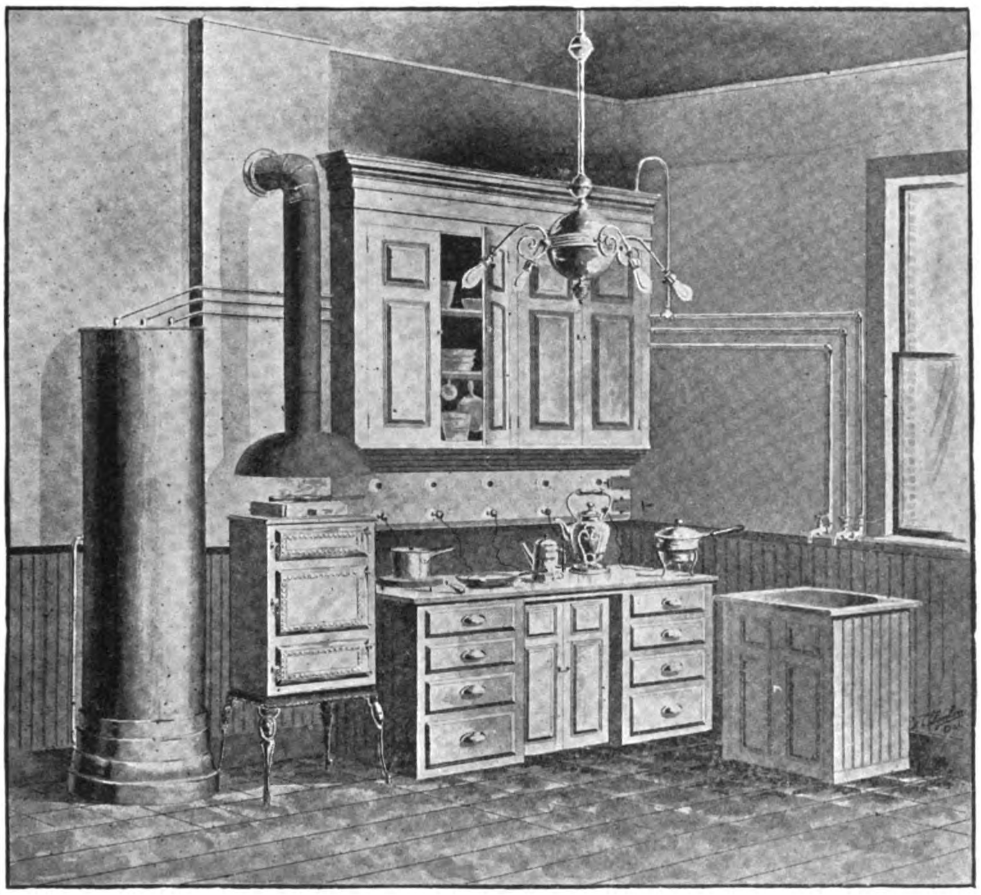


OVERHEAD CONSTRUCTION, BERNE POWER STATION. (SEE PAGE 303.)

Electric Heating.

BY W. S. KEY.

One after another the various departments in municipal, social and domestic economies are being entered by that subtle yet withal useful force, electricity; and so sure as it effects an entrance therein it makes itself so indispensable a factor that there is no thought entertained of retiring it again, for it is impressed into service as human ingenuity supplies the mechanical adjuncts, and all that remains is for some one to touch a button and electricity does the rest. Who could have thought fifteen years ago, nay, even ten years ago, that the business of electric lighting alone would have assumed the proportions it has to-day, to say nothing of the phenomenal growth of electric railways and the utilization of electricity for general power purposes? And yet there are the facts that never before in the history of theoretical or applied science has success been so quickly achieved as in this particular field, and the end is not yet.



A MODEL ELECTRICAL KITCHEN. (FIG. 1.)

The most recent development in electrical applications is that of heating; and while the world has almost had to gasp for breath as it has noted the rapid changes and improvements taking place in lighting and power, it will require a prophet and more than a prophet to predict when or where the ultimate limit shall be reached in the field of electric heating. This assertion is prompted by an unique experience the writer had a few days ago in Boston. It was a hungry and famishing crowd consisting of an even dozen newspaper men that assembled in a cosey kitchen belonging to the American Electric Heating Company, Boston, to watch the cooking of a first-class dinner by an Italian chef, after which the company were invited to partake of the toothsome viands which had been duly prepared without a spark of fire or a live coal or cinder being utilized.

The dinner was announced for 1 P. M., and at that hour the dozen guests were on hand and ready for the onslaught. Before that act was possible, however, they were invited to take possession of the kitchen and have their appetites whetted by watching the entire process of preparing and cooking every morsel of food they had been invited to partake of. The guests were naturally curious to watch the culinary operations, and in vain looked round to find anything resembling a stove or a cooking range. Instead of these usual devices there was a large cupboard overhead, as seen in the accompanying cut of this kitchen, wherein were ranged the various utensils. Extending along and fixed to the wall immediately below said cupboard was an electric switchboard, with plugs, sockets, cut outs, etc., such as are usually found where electricity is used. Then, as will be seen, there was a dresser or table on which the utensils in actual use stood, including coffee pot, plate warmer, saucepans, spider, steamer, pie plate, etc., each article looking identically like similar articles used in any ordinary kitchen, with this difference, that by means of a flexible silk cord, or incandescent lamp wire, each utensil was connected with the switchboard. At the end of this dresser stood a large oven; on top of this a grill, the fumes from which were conveyed away by means of a flue. Next there was a vertical copper boiler, such as is used in any house, the water pipes from which were conveyed to a sink stone and wash bowl on the opposite side of the kitchen where a plentiful supply of hot water could be obtained through ordinary faucets. Now every one of these pieces of domestic apparatus was being heated by electricity and doing as fine a piece of cooking as could be desired. The joint of beef in the oven sputtered in its gravy and emitted a most fragrant odor; the steak on the grill sizzled in an appetizing way for a few minutes till it was done to a turn, while the fragrant green peas steaming over the potatoes, and the aromatic Mocha brewing in the coffee urn, gave zest to the appetite, and held out promise of some interesting gastronomic exercises to follow. When dinner was at last announced—the cooking throughout taking about one-half the usual time—the guests fell to and did ample and speedy justice to the good things set before them, including fillet of soles, beautifully browned; lobster in sauce; roast of beef; steak, green peas, potatoes, French rolls and black coffee, which all declared were first class in every particular, and certainly more tasty than when cooked in the ordinary way.

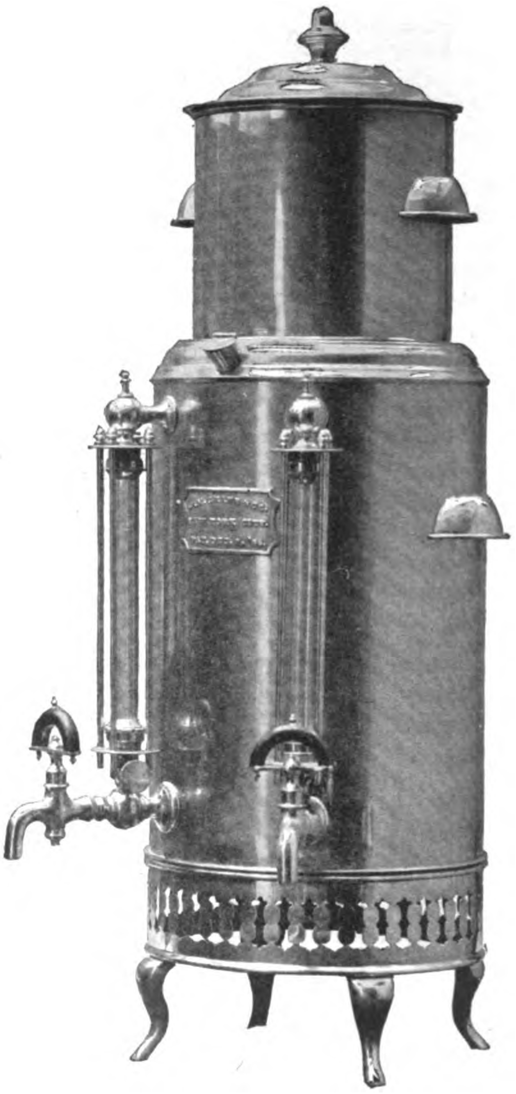
There were no post-prandial exercises, but during dinner the new departure in electrical science and its adaptability to the purposes of the cuisine were fully and freely discussed.

Then all were escorted to see the exhibition of devices which this company now own and are putting on the market, as well as to watch several of their experts at work evolving and developing new appliances and new uses for this process of electric heating, which uses bid fair for being to all intents and purposes illimitable.

Having thus given some account of the electrical kitchen, which is herewith accurately reproduced in Fig. 1, we may proceed to state that Fig. 2 represents an electric tea or coffee urn, Fig. 3 an electric plate or dish on which to keep a steak, chop or joint hot while being carved or eaten.

In this article it is impossible to enumerate one tithe of the devices shown. Suffice it to say that this electric heating process is being applied to tailors' irons, better known as "tailors' gooses"; to pressing irons for hatmakers; soldering irons for tinsmiths and braziers; cigar lighters; branding irons for stock-breeders; smoothing irons for laundry work; glue pots for carpenters' use, and many other similar uses.

The foregoing, however, do not exhaust the list, for this company have apparatus whereby, without the aid of furnace or any other heating device in cellars, houses and buildings of whatever kind can be heated by hot air or hot water. To accomplish this by hot air all that is needed is to place the electric radiator, Fig. 4, in a floor



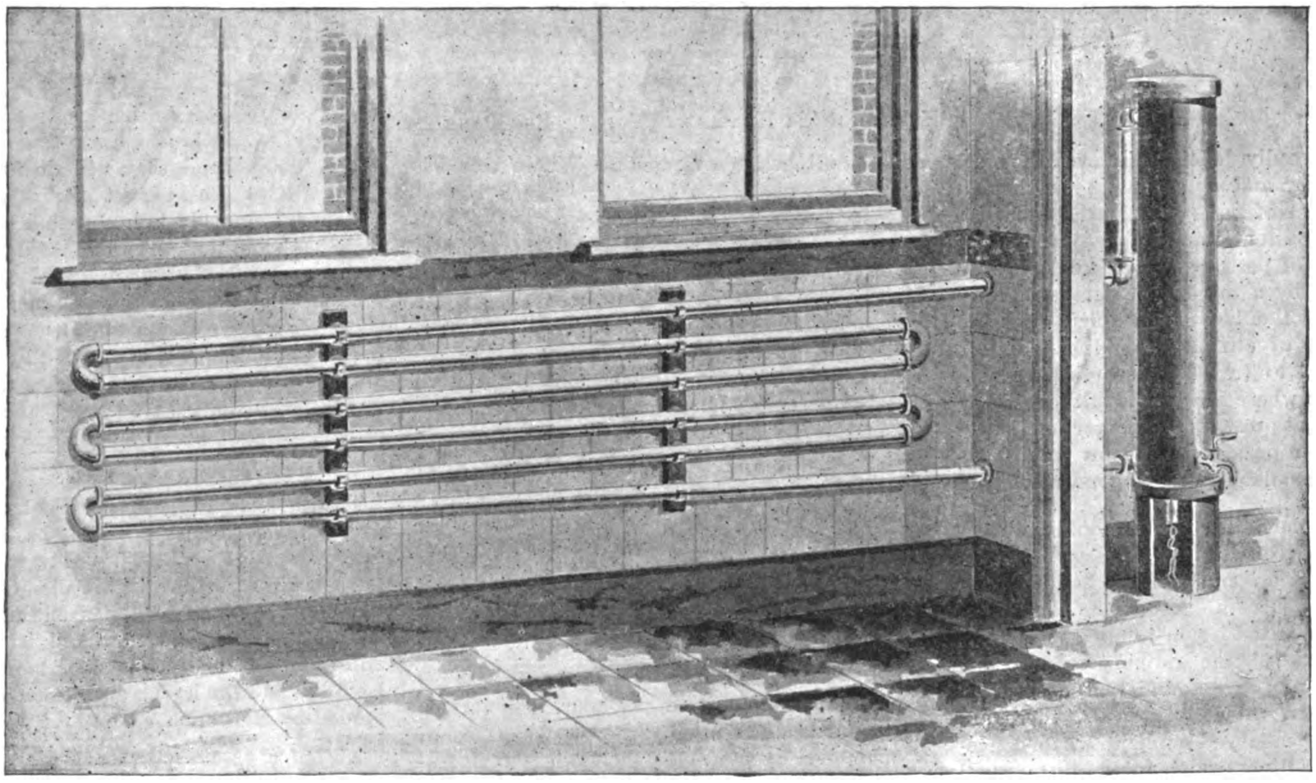
COFFEE AND TEA URN. (FIG. 2.)

register and turn on the current, when the air passing from the cellar, a cold air box, or from the outside, will be instantly heated, passing into the room and thereby creating a draught ensuring perfect ventilation. Or an ordinary water boiler, Fig. 5, can be heated with these radiators, thereby securing a circulation of steam or water, as the case may be, through the pipes and ordinary radiators as in daily use. The company likewise own a combination which secures certain degrees of heat sufficient to heat any place for hours after the current has been turned off, the necessary amount of heat having first been evolved.

PLATE STOVE. (FIG. 3.)

As will be seen from Fig. 6, which shows how a street car is heated by electricity, the pipes are arranged beneath the seats, and so perfect is this system, after many exhaustive experiments and tests, that an even and equable temperature of 55 degrees Fahr. can easily be maintained in the cars continuously whatever be the temperature outside, even down to zero or far below. The advantage of such a system of heating, doing away with the cost, care and dirt incidental to the use of stoves, will be appreciated by all. Incidentally it may be stated that this company own nearly all fundamental patents issued on car heating devices, whether the heat be produced by radiation or by connection, by the direct circulation of hot air or by the radiation of heat from suitable pipe surfaces. Of course it hardly needs to be stated that the current needed for car heating is taken from the trolley wire overhead.

In the metallurgical arts there is a wide field opening out for electric heating, and the assayer can heat his muffles to the finest shade of temperature by devices now available, while the smelter can dispense with all the smoke and dirt which accompany the use of coal or coke. During the exhibition last week a heat running up to something like 2,400 or 2,500 deg. Fahrenheit was evolved by electric current in very few minutes, melting white flinty sand so thoroughly in a crucible that when it cooled off it was converted into stone.



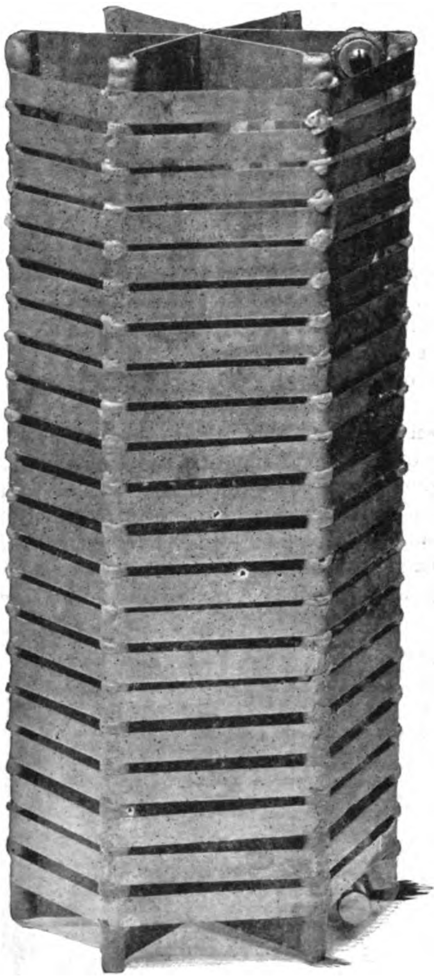
ELECTRIC HEATING BY HOT WATER CIRCULATION. (FIG. 5.)

For manufacturing jewelers there is a certain and complete revolution of business methods pending, for apparatus has been perfected by means of which gold and silver rings can be almost instantly soldered, and the welding of links in watch and other chains becomes child's play. And in the use of any and all of these various devices the question of economy is of supreme importance. The ordinary street current can be utilized, suitable devices having been perfected for transforming current to exactly what is needed for any purpose. Hitherto the costliness of electricity has stood in the way of its more general use; now this objection has become a thing of the past, and it goes without saying that it cannot and will not be long ere every one of the devices introduced to the world by this company will be in universal use and demand.

We have said but little of this remarkable step forward as compared with all we might have said, yet we have said sufficient to interest our readers in the most recent and promising departure in electrical science.

Before concluding we may state that the American Electric Heating Corporation, with a capital of $5,000,000, having its chief offices at 274 Purchase street, Boston, is composed of Mr. Edward Jewell, Boston, president; Arthur B. Smith, Boston, treasurer, and the following directors: A. M. Dodge and J. F. Tams, New York; H. C. Duell, Syracuse; F. D. Hager, St. Paul; Charles Odell, Salem; Ambrose Eastman and Ed. Jewell, Boston, and A. B. Smith, Cliftondale, all well known and wealthy business men in their respective communities. They have purchased all inventions and patents of any value on electric heating, and propose to do business on a most extensive scale.

The American Electric Heating Corporation will not manufacture or sell these goods, sub-companies having been organized for the manufacture and sale of these varied devices. Among these companies in the East are the Central Electric Heating Company, 26 Cortlandt street, New York, and the New England Electric Heating Company, 629 Atlantic avenue, Boston. These



COIL HEATER. (FIG. 4.)

and other sub-companies are already doing a flourishing business, though hitherto no effort has been made to interest the general public until now.

That the undertaking is bound to be an unqualified success is beyond all question, the demand having suddenly become both great and promising.

Electric Cooking and the Load Factor.*

The demand which is slowly, but surely, being coaxed into existence for electric sundries in the household is likely to have a most healthy action in increasing the load factor of our central stations, and in coming to the rescue of those engineers who have at present reason to groan over the day-load, or, rather, want of it. It is in its effects, rather than in itself, that electric cooking is of interest to us; but it may be well to chronicle the advances which have been made in some directions in the art. Of course, for some time to come electricity will be a luxury, or at the best an expensive necessity, to those who dabble in the enticing and scientifically-cleanly appliances which are now so much in evidence at the hands of Mr. Dowsing, and associated with the names of Carpenter, Binswanger, Crompton, Hirst and others.

The first asbestos-covered wire resistance coil appliances were sadly deficient in even the most elementary design and the wonder is that they do so well; but some of the recent patterns have a claim upon our attention, if only as examples of evolution, a proof positive that efficiency is only to be obtained by a mastery of details and by keeping in view the laws upon which even the simplest action of our domestic life is based. Where heat has to travel, air spaces have been done away with where not wanted, although they are very useful at present until the vacuum jacket which has been promised becomes *un fait accompli* and is available as a non-conducting wall for heat vessels.

Carpenter in the States and Crompton in England have buried highly-resisting wires in enamel, and such an arrangement has been exploited with fair success. About the same time, Binswanger and Hirst began to use a special vitreous cement, with platino-iridium wire embedded in it, and they, too, have found that despite the present costliness of such utensils, there are members of the moneyed public to whom convenience and novelty outweigh the, to them, small additional expense. Of course, the dealers benefit in the first instance, and the central stations always, so the latter cannot but regard such enterprising firms as their best friends in a time of need. The last-named vitreous enamel can be applied to any existing vessel, and the absence of firing marks the distinction between it and the Carpenter system. Recent tests have shown that the heating of water is practically (a self-evident fact to the most primitive physicist) the most trying task electricity can be given.

The first design of heater was akin to the toddy ladel, but was soon displaced by a kettle provided below with the resistance wire. In such a form a kettle containing two pints of cold water can, it is said, be brought up to boiling point with five amperes at 100 volts, in from 16 to 18 minutes. If we say 20 minutes, to be on the safe side, it may be taken that one-sixth of a unit would be required for each charge; that is, at present average prices, it costs ½d. to boil 1 pint of cold water by electricity. Sixty watt hours have achieved this feat under test conditions, and the application of the principles of calorimetry have caused the efficiency to go up till little further can be expected as to improvement in this direction.

Seventy-five per cent. to 80 per cent. can be guaranteed as a return of the total heat energy of the current supplied, and no perceptible difference has yet been found between the effectiveness of alternating and continuous supply. The loss is simply one of radiation which it is impossible to altogether overcome. Where this has been counteracted, 90 per cent. return has resulted. Bolder attempts are being made with large ovens and appliances for hotel kitchens, and with these notable results have been obtained. Mr. Binswanger's latest oven, 20 inches by 14 inches by 18 inches, can be kept up 350 degs. F. to 400 degs. F. for three hours by an expenditure of 1,200 watts if it has been brought up to working heat with 1,800 watts, and the first heating of the contents done with this energy.

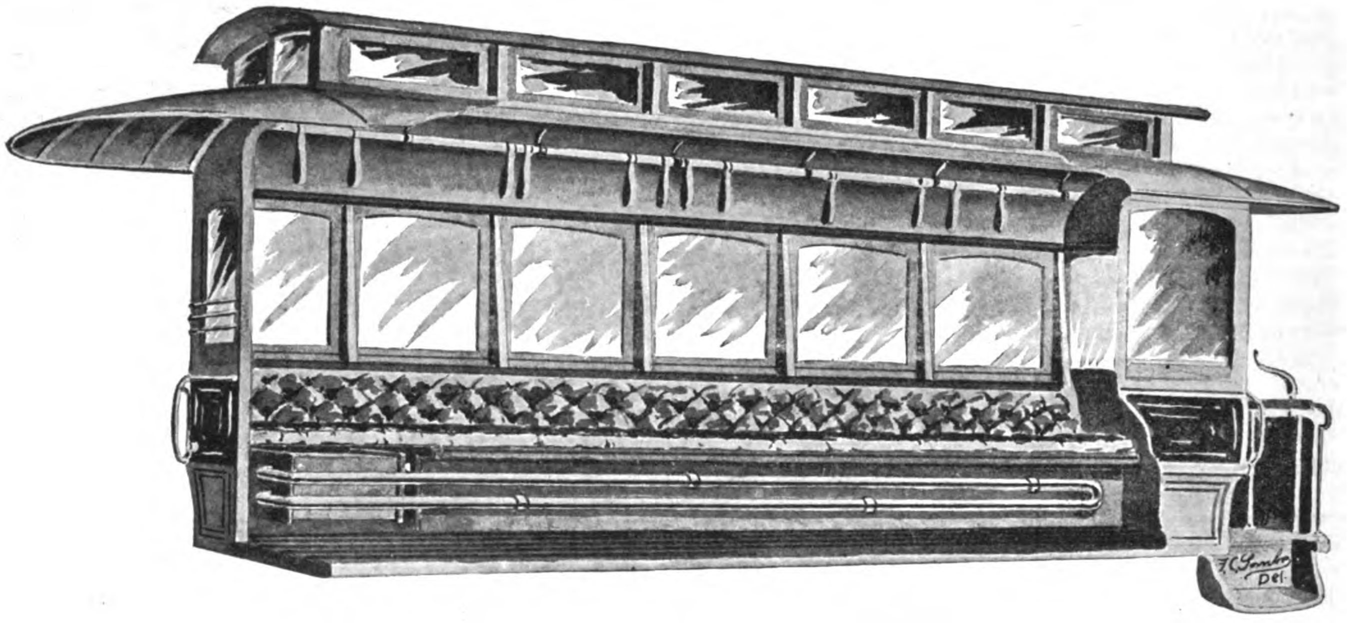
In the latest small heater, one pint of water can be raised from 15 degs. C. to 100 degs. C. by 75 watt-hours, showing an efficiency of 73 per cent. The small curling-iron heater takes ¾ ampere at 100 volts for 1½ minutes to raise it from 15 degs. C. to 200 degs. C., say, a demand of 75 watts for an infinitesimal time per diem. Irons of large sizes are being handled. A tailor's goose, weighing 15 lbs., while at work, takes 4 amperes at 100 volts, or 400 watts, say 2d. per hour. The surface heater for badly-ventilated rooms and offices of about 10 feet by 12 feet, to maintain a temperature of 60 degs. F. during winter weather, absorbs five amperes at 100 volts, or half a unit per hour, and although outrageously extravagant compared with gas fires, there seems to be a likelihood of many a city man blessing the company which burns coal across the river to supply the heat for his comfort in the densest part of the city itself.

It cannot be enforced too strongly that the cost of all such service performed by electrical means must always be far above anything chargeable to gas. To produce heat by the operation of the $C^2 R$ law means the erection and maintenance of three separate sets of plant at one locality, the losses in which must certainly be paid for by the consumer, and in addition to this he has to pay his share of the maintenance of a costly and extensive system of mains and converters—a system whose capitalized cost reduced to per unit per consumer is out of all proportion to the equivalent in a net-work of gas mains.

To supply 200 heaters of the size mentioned would require a boiler, an engine, and a dynamo plant, each of 100 kilowatt capacity, whereas for gas supply the storage provided would be capable of dealing with many thousand such appliances and call for no increase.

Notwithstanding this fact, there is no doubt that the sooner central stations follow the lead of the gas companies and inaugurate, by their own efforts, a system of hiring, of hire-purchase and rental of domestic heating and cooking appliances, the sooner will their profits be proportionate to the scientific success of the industry.

If the domestic applications do not do all that some fondly hope they will do for electricity, they will at least assist the other economies which are already being practised by station managers, and tend towards that desirable result—the payment of a fair dividend to the shareholders, and a proportionate remuneration to those engaged in the operations of supply. Approximately, the cost of heating by electricity is about ten times the cost of gas, taking gas at 2s. 6d., electricity at 3d., and theoretical efficiency.



ELECTRIC CAR HEATING. (FIG. 6. SEE PAGE 299.)

A Long Cable.

The duplicate cable of the Central and South American Telegraph Company has been successfully laid by the steamship Silvertown. It extends in three sections from Salina Cruz, Mex., to Chorillos, Peru, via San Juan del Sur, Nicaragua, and Santa Elena, Ecuador, and is nearly 2,500 miles long. The cable was manufactured in London, and the laying operations were superintended by Herbert Kingsford, engineer and electrician.

It Shows Progress.

The *Architects' Electrical Bulletin* for June shows a marked improvement over previous issues. It is entirely creditable to its publishers, and is indeed a well edited "monthly review of the art of electric wiring."

---

* From the *Electrical Review*, London

ON LIGHT AND OTHER HIGH FREQUENCY PHENOMENA.—III.

BY NIKOLA TESLA.*

It is desirable, in order to maintain the vibration economically, to reduce the impact and frictional losses as much as possible. As regards the latter, which in the electrical analogue correspond to the losses due to the resistance of the circuits, it is impossible to obviate them entirely, but they can be reduced to a minimum by a proper selection of the dimensions of the circuit and by the employment of thin conductors in the form of strands. But the loss of energy caused by the first breaking through of the dielectric—which in the above example corresponds to the violent knock of the bottom against the inelastic stop—would be more important to overcome. At the moment of the breaking through, the air space has a very high resistance, which is probably reduced to a very small value when the current has reached some strength and the space is brought to a high temperature. It would materially diminish the loss of energy if the space were always kept at an extremely high temperature, but then there would be no disruptive break. By warming the space moderately by means of a lamp or otherwise, the economy as far as the arc is concerned is sensibly increased. But the magnet or other interrupting device does not diminish the loss in the arc. Likewise, a jet of air only facilitates the carrying off of the energy. Air, or a gas in general, behaves curiously in this respect. When two bodies, charged to a very high potential, discharge disruptively through an air space, any amount of energy may be carried off by the air. This energy is evidently dissipated by bodily carriers in impact and collisional losses of the molecules. The exchange of the molecules in the space occurs with inconceivable rapidity. A powerful discharge taking place between two electrodes, they may remain entirely cool, and yet the loss in the air may represent any amount of energy. It is perfectly practicable, with very great potential differences in the gap, to dissipate several horse-power in the arc of the discharge without even noticing a small increase in the temperature of the electrodes. All the frictional losses occur then practically in the air. If the exchange of the air molecules is prevented, as by enclosing the air hermetically, the gas inside the vessel is brought quickly to a high temperature, even with a very small discharge. It is difficult to estimate how much of the energy is lost in sound waves, audible or not, in a powerful discharge. When the currents through the gap are large, the electrodes may become rapidly heated, but this is not a reliable measure of the energy wasted in the arc, as the loss through the gap itself may be comparatively small. The air or a gas in general is, at ordinary pressures at least, clearly not the best medium through which a disruptive discharge should occur. Air or other gas under great pressure is of course a much more suitable medium for the discharge gap. I have carried on long-continued experiments in this direction, unfortunately less practicable on account of the difficulties and expense in getting under great pressure. But even if the medium in the discharge space is solid or liquid, still the same losses take place, though they are generally smaller, for just as soon as the arc is established the solid or liquid is volatilized. Indeed, there is no body known which would not be disintegrated by the arc, and it is an open question among scientific men whether an arc discharge could occur at all in the air itself without the particles of the electrodes being torn off. When the current through the gap is very small and the arc very long, I believe that a relatively considerable amount of heat is taken up in the disintegration of the electrodes, which partially on this account may remain quite cold.

The ideal medium for a discharge gap should only *crack*, and the ideal electrode should be of some material which cannot be disintegrated. With small currents through the gap it is best to employ aluminum, but not when the currents are large. The disruptive break in the air, or more or less in any ordinary medium, is not of the nature of a crack, but is rather comparable to the piercing of innumerable bullets through a mass offering great frictional resistance to the motion of the bullets, this involving considerable loss of energy. A medium which would merely crack when strained electrostatically—and this possibly might be the case with a perfect vacuum, that is, pure ether—would involve a very small loss in the gap, so small as to be entirely negligible, at least theoretically, because a crack may be produced by an infinitely small displacement. In exhausting an oblong bulb provided with two aluminum terminals with the greatest care I have succeeded in producing such a vacuum that the secondary discharge of a disruptive discharge coil would break disruptively through the bulb in the form of fine spark streams. The curious point was that the discharge would completely ignore the terminals and start far behind the two aluminum plates which served as electrodes. This extraordinarily high vacuum could only be maintained for a very short while. To return to the ideal medium, think, for the sake of illustration, of a piece of glass or similar body clamped in a vise, and the latter tightened more and more. At a certain point a minute increase of the pressure will cause the glass to crack. The loss of energy involved in splitting the glass may be practically nothing, for though the force is great the displacement need be but extremely small. Now imagine that the glass would possess the property of closing again perfectly the crack upon a minute diminution of the pressure. This is the way the dielectric in the discharge space should behave. But inasmuch as there would be always some loss in the gap the medium, which should be continuous, should exchange through the gap at a rapid rate. In the preceding example, the glass being perfectly closed, it would mean that the dielectric in the discharge space possesses a great insulating power; the glass being cracked, it would signify that the medium in the space is a good conductor. The dielectric should vary enormously in resistance by minute variations of the E. M. F. across the discharge space. This condition is attained, but in an extremely imperfect manner, by warming the air space to a certain critical temperature, dependent on the E. M. F. across the gap, or by otherwise impairing the insulating power of the air. But as a matter of fact the air does never break down *disruptively*, if this term be rigorously interpreted, for before the sudden rush of the current occurs there is always a weak current preceding it, which rises first gradually and then with comparative suddenness. That is the reason why the rate of change is very much greater when glass, for instance, is broken through than when the break takes place through an air space of equivalent dielectric strength. As a medium for the discharge space a solid, or even a liquid, would be preferable therefore. It is somewhat difficult to conceive of a solid body which would possess the property of closing instantly after it has been cracked. But a liquid, especially under great pressure, behaves practically like a solid, while it possesses the property of closing the crack. Hence it was thought that a liquid insulator might be more suitable as a dielectric than air. Following out this idea, a number of different forms of dischargers in which a variety of such insulators, sometimes under great pressure, were employed, have been experimented upon. It is thought sufficient to dwell in a few words upon one of the forms experimented upon. One of these dischargers is illustrated in Figs. 4*a* and 4*b*.

A hollow metal pulley P (Fig. 4*a*) was fastened upon an arbor *a*, which by suitable means was rotated at a considerable speed. In the inside of the pulley, but disconnected from the same, was supported a thin disc h_1 (which is shown thick for the sake of clearness) of hard rubber, in which were embedded two metal segments *s s* with metallic extensions *e e* into which were screwed conducting terminals *t t* covered with thick tubes of hard rubber *t t*. The rubber disc *h* with its metallic segments *s s* was finished in a lathe, and its entire surface highly polished so as to offer the smallest possible frictional resistance to the motion through a fluid. In the hollow of the pulley an insulating liquid such as a thin oil was poured so as to reach very nearly to the opening left in the flange *f*, which was screwed tightly on the front side of the pulley. The terminals *t t* were connected to the opposite coatings of a battery of condensers so that the discharge occurred through the liquid. When the pulley was rotated the liquid was forced against the rim of the pulley and considerable fluid pressure resulted. In this simple way the discharge gap was filled with a medium which behaved practically like a solid, which possessed the quality of closing instantly upon the occurrence of the break, and which moreover was circulating through the gap at a rapid rate. Very powerful effects were produced by dischargers of this kind with liquid interrupters, of which a number of different forms were made. It was found that, as expected, a longer spark for a given length of wire was obtainable in this way than by using air as an interrupting device. Generally the speed, and therefore also the fluid pressure, was limited by reason of the fluid friction, in the form of discharger described, but the practically obtainable speed was more than sufficient to produce a number of breaks suitable for the circuits ordinarily used. In some instances the metal pulley P was provided with a few projections inwardly, and a definite number of breaks were then produced which could be computed from the speed of rotation of the pulley. Experiments were also carried on with liquids of different insulating power with the view of reducing the loss in the arc. When an insulating liquid is moderately warmed the loss in the arc is diminished.

A point of some importance was noted in experiments with various dischargers of this kind. It was found, for instance, that whereas the conditions maintained in these forms were favorable for the production of a great spark length, the currents so obtained were not best suited to the production of light effects. Experience undoubtedly has shown that for such purposes a harmonic rise and fall of the potential is preferable. Be it that a solid is rendered incandescent, or phosphorescent, or be it that energy is transmitted by condenser coating through the glass, it is quite certain that a harmonically rising and falling potential produces less destructive action, and that the vacuum is more permanently maintained. This would be easily explained if it were ascertained that the process going on in an exhausted vessel is of an electrolytic nature.

In the diagrammatical sketch, Fig. 1, which has been already referred to, the cases which are most likely to be met with in practice are illustrated. One has at his disposal either direct or alternating currents from a supply station. It is convenient for an experimenter in an isolated laboratory to employ a machine G such as illustrated, capable of giving both kinds of currents. In such case it is also preferable to use a machine with multiple circuits, as in many experiments it is useful and convenient to have at one's disposal currents of different phases. In the sketch, D represents the direct and A the alternating circuit. In each of these, three branch circuits are shown, all of which are provided with double lines switches *s s s s s s*. Consider first the direct current conversion; 1*a* represents the simplest case. If the E. M. F. of the generator is sufficient to break through a small air space, at least when the latter is warmed or otherwise rendered poorly insulating, there is no difficulty in maintaining a vibration, with fair economy by judicious adjustment of the capacity, self-induction and resistance of the circuit L containing the devices *l l m*. The magnet N, S, can be in this case advantageously combined with the air space. The discharger *d d* with the magnet may be placed either way, as indicated by the full or by the dotted lines. The circuit 1*a* with the connections and devices is supposed to possess dimensions such as are suitable for the maintenance of a vibration. But usually the E. M. F. on the circuit or branch 1*a* will be something like 100 volts or so, and in this case it is not sufficient to break through the gap. Many different means may be used to remedy this by raising the E. M. F. across the gap. The simplest is probably to insert a large self-induction coil in series with the circuit L. When the arc is established, as by the discharger illustrated in Fig. 2, the magnet blows the arc out the instant it is formed. Now the extra current of the break, being of high E. M. F., breaks through the gap, and a path of low resistance for the dynamo current being again provided, there is a sudden rush of the current from the dynamo upon the weakening or subsidence of the extra current. This process is repeated in rapid succession, and in this manner I have maintained oscillation with as low as 50 volts, or even less, across the gap. But conversion on this plan is not to be recommended on account of the too heavy currents through the gap and consequent heating of the electrodes; besides, the frequencies obtained in this way are low, owing to the high self induction necessarily associated with the circuit. It is very desirable to have the E. M. F. as high as possible, first, in order to increase the economy of the conversion, and secondly, to obtain high frequencies. The difference of potential in this electric oscillation is, of course, the equivalent of the stretching force in the mechanical vibration of the spring. To obtain very rapid vibration in a circuit of some inertia a great stretching force or difference of potential is necessary. Incidentally, when the E. M. F. is very great, the condenser which is usually employed in connection with the circuit need have but a small capacity, and many other advantages are gained. With a view of raising the E. M. F. to a many times greater value than obtainable from ordinary distribution circuits, a rotating transformer *g* is used, as indicated in Fig. 2*a*, or else a separate high potential machine is driven by means of a motor operated from the generator G. The latter plan is in fact preferable, as changes are easier made. The connections from the high tension winding are quite similar to those in branch 1*a* with the exception that a condenser C, which should be adjustable, is connected to the high tension circuit. Usually, also, an adjustable self-induction coil in series with the circuit has been employed in these experiments. When the tension of the currents is very high the magnet ordinarily used in connection with the discharger is of comparatively small value, as it is quite easy to adjust the dimensions of the circuit so that oscillation is maintained. The employment of a steady E. M. F. in the high frequency conversion affords some advantages over the employment of alternating E. M. F. as the adjustments are much simpler and the action can be easier controlled. But unfortunately one is limited by the obtainable potential difference. The windings also break down easily in consequence of the sparks which form between the sections of the armature or commutator when a vigorous oscillation takes place. Besides, these transformers are expensive to build. It has been found by experience that it is best to follow the plan illustrated in Fig. 3*a*. In this arrangement a rotating transformer *g* is employed to convert the low tension direct currents into low frequency alternating currents, preferably also of small tension. The tension of the currents is then raised in a stationary transformer T. The secondary S of this transformer is connected to an adjustable condenser C, which discharges through the gap or discharger *d d*, placed in either of the ways indicated, through the primary P of a disruptive discharge coil, the high frequency currents being obtained from the secondary S of this coil, as described on previous occasions. This will undoubtedly be found the cheapest and most convenient way of converting direct currents.

---

* A lecture delivered before the Franklin Institute at Philadelphia, Feb. 24, 1893, and before the National Electric Light Association at St. Louis, Mo., March 1, 1893.

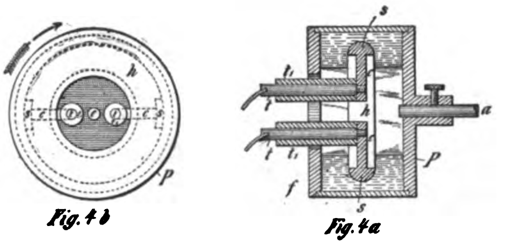


Fig. 4 b *Fig. 4 a*

FORM OF DISCHARGER WITH LIQUID INTERRUPTER.

The three branches of the circuit A represent the usual cases met in practice when alternating currents are converted. In Fig. 1*b* a condenser C, generally of large capacity, is connected to the circuit L, containing the devices *l l*, *m m*. The devices *m m* are supposed to be of high self-induction so as to bring the frequency of the circuit more or less to that of the dynamo. In this instance the discharger *d d* should best have a number of makes and breaks per second equal to twice the frequency of the dynamo. If not so, then it should have at least a number equal to a multiple or even fraction of the dynamo frequency. It should be observed, referring to 1*b*, that the conversion to a high potential is also effected when the discharger *d d*, which is shown in the sketch, is omitted. But the effects which are produced by currents which rise instantly to high values, as in a disruptive discharge, are entirely different from those produced by dynamo currents which rise and fall harmonically. So, for instance, there might be in a given case a number of makes and breaks at *d d* equal to just twice the frequency of the dynamo, or in other words there may be the same number of fundamental oscillations as would be produced without the discharge gap, and there might even not be any quicker superimposed vibration; yet the differences of potential at the various points of the circuit, the impedence and other phenomena, dependent upon the rate of change, will bear no similarity in the two cases. Thus, when working with currents discharging disruptively, the element chiefly to be considered is not the frequency, as a student might be apt to believe, but the rate of change per unit of time. With low frequencies in a certain measure the same effects may be obtained as with high frequencies, provided the rate of change is sufficiently great. So, if a low frequency current is raised to a potential of say 75,000 volts and the high tension current passed through a series of high resistance lamp filaments, the importance of the rarefied gas surrounding the filament is clearly noted, as will be seen later; or, if a low frequency current of several thousand amperes is passed through a metal bar, striking phenomena of impedence are observed, just as with currents of high frequencies. But it is, of course, evident that with low frequency currents it is impossible to obtain such rates of change per unit of time as with high frequencies, hence the effects produced by the latter are much more prominent. It was deemed advisable to make the preceding remarks, inasmuch as many more recently described effects have been unwittingly identified with high frequencies. Frequency alone in reality does not mean anything, except when an undisturbed harmonic oscillation is considered.

In the branch 3*b* a similar disposition as in 1*b* is illustrated, with the difference that the currents discharging through the gap *d d* are used to induce currents in the secondary S of a transformer T. In such case the secondary should be provided with an adjustable condenser for the purpose of tuning it to the primary.

Fig. 2*b* illustrates a plan of alternate current high frequency conversion which is most frequently used and which is found to be most convenient. This plan has been dwelt upon in detail on previous occasions and need not be described here.

Some of these results were obtained by the use of a high frequency alternator. A description of such machines will be found in my original paper before the American Institute of Electrical Engineers, and in periodicals of that period, notably in the *Electrical Engineer* of March 18, 1891.

ON PHENOMENA PRODUCED BY ELECTROSTATIC FORCE.

The first class of effects I intend to show you are effects produced by electrostatic force. It is the force which governs the motion of the atoms, which causes them to collide and develop the life-sustaining energy of heat and light, and which causes them to aggregate in an infinite variety of ways, according to Nature's fanciful designs, and to form all these wondrous structures we perceive around us; it is, in fact, if our present views be true, the most important force for us to consider in nature. As the term *electrostatic* might imply a steady electric condition, it should be remarked that in these experiments the force is not constant, but varies at a rate which may be considered moderate, about one million times a second, or thereabouts. This enables me to produce many effects which are not produceable with an unvarying force.

When two conducting bodies are insulated and electrified, we say that an electrostatic force is acting between them. This force manifests itself in attractions, repulsions and stresses in the bodies and space or medium without. So great may be the strain exerted in the air, or whatever separates the two conducting bodies, that it may break down, and we observe sparks or bundles of light or streamers, as they are called. These streamers form abundantly when the force through the air is rapidly varying. I will illustrate this action of electrostatic force in a novel experiment in which I will employ the induction coil before referred to. The coil is contained in a trough filled with oil, and placed under the table. The two ends of the secondary wire pass through the two thick columns of hard rubber which protrude to some height above the table.

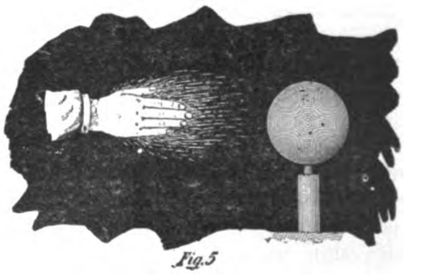

Fig. 5

ILLUSTRATING THE EFFECT OF VARYING ELECTROSTATIC FORCE WITH A TRANSFORMER OF 200,000 VOLTS PRESSURE.

It is necessary to insulate the ends or terminals of the secondary heavily with hard rubber, because even dry wood is by far too poor an insulator for these currents of enormous potential differences. On one of the terminals of the coil, I have placed a large sphere of sheet brass, which is connected to a larger insulated brass plate, in order to enable me to perform the experiments under conditions which, as you will see, are more suitable for this experiment. I now set the coil to work and approach the free terminal with a metallic object held in my hand, this simply to avoid burns. As I approach the metallic object to a distance of eight or ten inches, a torrent of furious sparks breaks forth from the end of the secondary wire, which passes through the rubber column. The sparks cease when the metal in my hand touches the wire. My arm is now traversed by a powerful electric current, vibrating at about the rate of one million times a second. All around me the electrostatic force makes itself felt, and the air molecules and particles of dust flying about are acted upon and are hammering violently against my body. So great is this agitation of the particles that when the lights are turned out you may see streams of feeble light appear on some parts of my body. When such a streamer breaks out on any part of the body it produces a sensation like the pricking of a needle. Were the potentials sufficiently high and the frequency of the vibration rather low, the skin would probably be ruptured under the tremendous strain, and the blood would rush out with great force in the form of fine spray or jet so thin as to be invisible, just as oil will when placed on the positive terminal of a Holtz machine. This breaking through of the skin, though it may seem impossible at first, would perhaps occur by reason of the tissues under the skin being incomparably better conductors. This at least appears plausible judging from some observations.

I can make these streams of light visible to all by touching with the metallic object one of the terminals as before, and approaching my free hand to the brass sphere, which is connected to the second terminal of the coil. As the hand is approached the air between it and the sphere, or in the immediate neighborhood, is more violently agitated, and you see streams of light now break forth from my finger tips and from the whole hand (Fig. 5). Were I to approach the hand closer, powerful sparks would jump from the brass sphere to my hand, which might be injurious. The streamers offer no particular inconvenience, except that in the ends of the finger tips a burning sensation is felt. They should not be confounded with those produced by an influence machine, because in many respects they behave differently. I have attached the brass sphere and plate to one of the terminals in order to prevent the formation of visible streamers on that terminal, also in order to prevent sparks from jumping at a considerable distance. Besides, the attachment is favorable for the working of the coil.

(To be continued.)

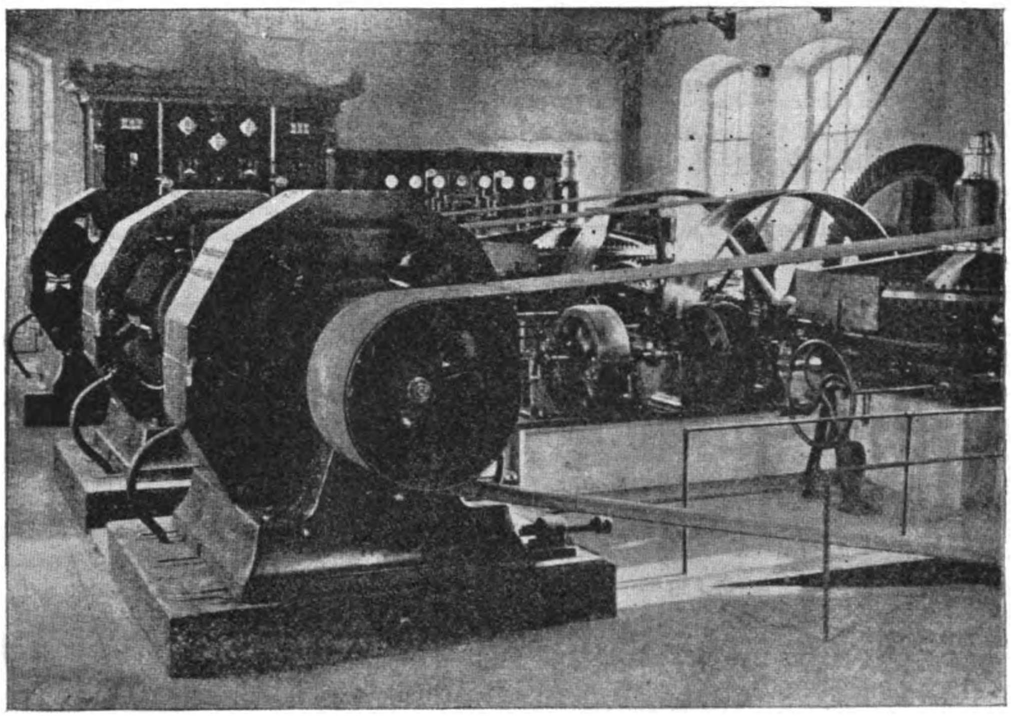

FIG. 2.

The Berne Hydraulic Power Station.

Berne, Switzerland, is one of those fortunate towns which have water power available, and one of those still more fortunate towns which have authorities who are willing to advance with the times. The power station, which is described in *Industries*, is driven by water power from the river Aare, which has a fall of about ten feet, with a volume of water representing about 400 H. P. Fig. 1 shows in elevation the arrangement of the station, which is built above the water race, while Fig. 2 shows a general view of the turbines and dynamos. There are three turbines of 120 H. P. each, and three direct-current dynamos to correspond. The third turbine, however, is also coupled to a shaft from which power is taken to drive a neighboring tramway system. The turbines all work on one shaft, which runs at 125 revolutions per minute. A spur wheel takes off power for the compressors of the tramway system. The turbines, which are of the Jonval type, can be uncoupled by clutches placed between them.

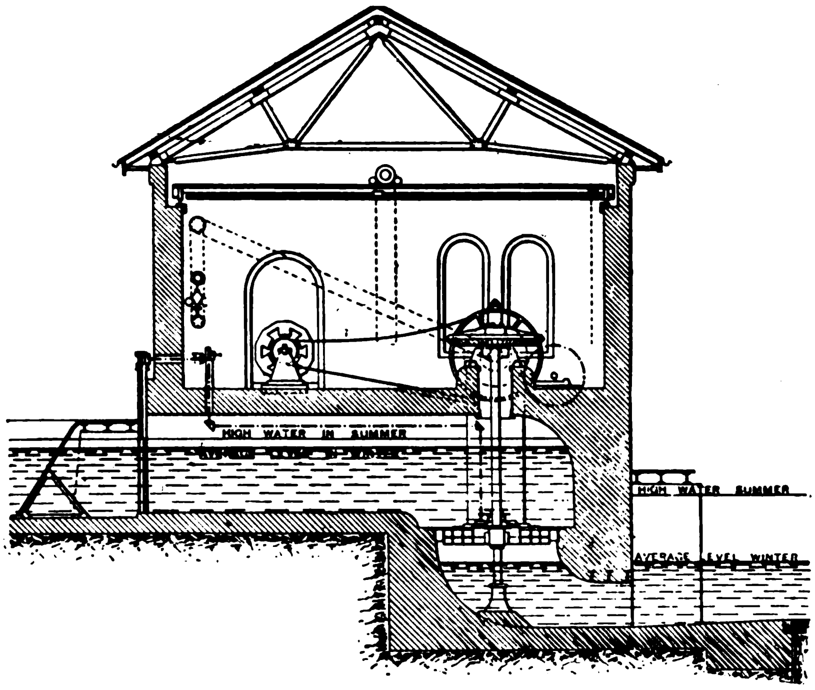

FIG. 1.

The dynamos are of the Maschinen Fabrik Oerlikon six-pole type. One is held in reserve; and accumulators of the Hagen type are employed, as the water power is not sufficient to run at full load without them. The dynamos are wound for charging accumulators, with three pairs of brushes in parallel, and give 120-140 volts and 84,000 watts at 450 revolutions per minute. The battery house is a well ventilated building containing 144 "Tudor" cells, of which 32 are connected to the switches; the capacity being 690 ampere hours.

The distribution is carried out on the three-wire system. An ingenious method of dealing with the batteries is employed. A couple of dynamotors are used, so that extra pressure can be given to the cell circuit even if the dynamos are connected to the town mains. In fact, an extra electromotive force can be put in the battery circuit. The battery is also regulated for discharging by an automatic switch, which is controlled by a relay, which is in its turn controlled by a sensitive voltmeter. This apparatus is found to work perfectly and promptly, and no variations of pressure are observed on the mains or lamps.

The station begins supply with what is equivalent to 6,000 eight C. P. lamps arranged on a network fed by three pairs of feeders and two compensation leads. The circuit is carried from the station for half a mile along the banks of the Aare. Eight overhead cables are employed. Pilot wires to the automatic governors are also led to the network. The leads are carried into an underground chamber in Münzt Terrace, where there are means of testing the cables when necessary, and lightning protectors are arranged for the overhead mains just mentioned.

The underground system, which supplies the whole town, is laid with Berthoud-Borel lead-covered cables, which are placed in impregnated wood casing. The public lighting is carried out with thirty Pilsen arc lamps. The railway station also takes fifty 10-ampere arc lamps.

The Frontispiece shows the overhead construction along the banks of the river Aare.

ELECTRICITY.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

A Suicidal Mistake.

The reflections of the officers and directors of the Electric Trust, when they turn the pages of ELECTRICITY and scan them closely (as they all do), cannot be pleasant. They cannot fail to notice that in our advertising department there are no less than seven makers of incandescent lamps represented. They are as follows: The Packard, Novak, Columbia, New Sunbeam, American, Buckeye and Westinghouse. This list will be added to within a few days.

We say the reflections of the officers and directors of the Trust cannot be pleasant when they take notice of this list.

If the most sanguine man in the Trust, even Mr. Coffin himself, had been asked in January, 1892, if the Trust scheme could be successful without the Edison lamp patent, he would have answered emphatically "No."

This lamp patent, with the direct and indirect benefits attached to it, was the one thing on which the Trust relied to pull them through. It is indeed more than probable that an absolute monopoly of the lamp business, such as was thoroughly tried for, would have placed the Trust on a solid financial footing, and given it a grip on the entire business that could not have been shaken in the next generation.

It was estimated that before the closing down of the Sawyer-Man factory 25,000 lamps per day were being made by independent companies. If the Trust had secured all the business they might easily have made a profit of 30 cents per lamp, or $7,500 a day, which would have been an addition to their income of $2,500,000 a year on lamps alone.

But an absolute monopoly was an impossibility, and the stupendous blunder of the Trust was in not properly appreciating this fact after the New York, Hartford and Chicago decisions.

At that time, and we speak with full knowledge on the subject, every independent lamp company of consequence in the United States was willing to pay a royalty of 8 cents to 10 cents per lamp sold.

A proposition on this basis from one of the largest companies was laid before the Trust, and it is believed that Mr. Coffin was in favor of accepting it, but was finally induced to defer to the judgment of Mr. F. P. Fish, who was thoroughly convinced in his own mind that the lamp business could be bottled up. The proposition was not accepted. And herein was the error of judgment, the utter misunderstanding of the situation, which can only be called a suicidal mistake.

By allowing the independent companies to manufacture on a royalty basis, the Trust could have had a sure net income of about $750,000 a year from this source, an income which has been forever thrown away and which can never be recovered.

And moreover, the unreasonable and arbitrary treatment of the independent manufacturers, the threatening of their customers, has so stirred up public sentiment against the Trust that even its own legitimate lamp business will suffer serious injury within the next year.

When the reputation of the new lamps has been thoroughly established, consumers almost without exception will buy them in preference to Trust lamps. And central station men, even Edison licensees, are already buying the new lamps in large numbers, not as a matter of sentiment alone, but because they are better lamps.

* * *

Electric Heating and Cooking.

The latest trend of electrical work is in the direction of heating and cooking apparatus, and these applications are being diligently pursued both here and abroad. As is usual, the cost of operating these devices is raised as the final determination of their utility, but as electrical apparatus is used in a very different way from coal or gas, with which it is generally compared, it is hardly fair to the former to make a direct and unqualified comparison of these methods.

If we consider the cost of current necessary to maintain a certain degree of heat during a definite time in comparison to the cost of coal to produce the same heating effect during the same time, coal naturally has the advantage; but the time factor is the all-important one, which makes direct comparison of the two methods impossible. For ordinary household work, such as cooking, the cost per hour of maintaining a coal stove is considerably less than that of an electric heater, but with the latter the consumption of energy is limited to the time that the heat is actually utilized, while with the former at least a moderate fire must be kept up during the day in order to be available when desired.

For this reason it appears idle to make any general comparison between the costs of these methods, as the economy of either is only determined by the conditions under which it is used.

* * *

Telephones vs. Traction.

The question of the exclusive right of ground return circuit for telephone lines, which was hotly contested in this country on the introduction of electric railways, has been prominently brought before the public in England, where the same difficulty is arising between these rival claimants to the earth. There are two contentions in regard to this subject, each having too much merit to allow the decision to be given offhand. The railway companies claim an equal right to the use of a ground circuit with the telephone companies, which could hardly be questioned if both were entering the field at the same time, but the telephone companies claim that the railway circuits make part of their plant useless, and so interrupt and render almost worthless an already established business, and on this basis many suits have been brought to recover the expense of supplying the necessary metallic returns for the telephone lines.

The courts have generally settled this point in favor of the railway companies, but whichever way the decision may be it is of the greatest advantage to secure a complete metallic circuit for the telephone lines as the service is very materially improved by this means, and while the ground circuit is essential to the railways it is a decided defect in the telephone, and its adoption is only a matter of economy in the latter case which acts as a detriment to the service.

The Anti-Trust Congress. After a display of ignorance and buncombe which has never been excelled, the Anti-Trust Congress at Chicago has closed its sessions.

When the list of attendants was announced the general tone of the proceedings might have been accurately foretold. Wherever Ignatius Donnelly is a welcome guest, sensible men are not likely to be found. And it is a misfortune to the public that such a gathering was held.

The remedies proposed were varied, but were all socialistic in tendency. Not even Mr. Rosewater had a mild or sweet-scented policy to propose.

The present law is good enough, and if its provisions were properly carried out it would result in the disbanding of nearly all the Trusts.

But the common mistake in discussing the evils of Trusts and their remedies is in laying too much stress on the law and too little on personal effort.

There are laws to protect the respectable citizen from the highwayman, and officers for their enforcement. Yet if a man is attacked by a highwayman, and no officer is near, he does not wait for the law to protect him, he protects himself and fights.

This is the principle which has been acted upon in the electrical trade for nearly a year. Led by ELECTRICITY the independent concerns have been fighting a good battle, and the result is no longer in doubt.

It will require no special and extraordinary laws to rid the country of the Electric Trust.

* * *

The Entering Wedge. The Electric Trust, which abstained for nearly a fortnight from taking legal action against any one, has again endeavored to revive its lost prestige by bringing suit against the owners of the Holland House, Imperial Hotel and a large office building in Spruce street for infringing its expiring lamp patent, and it has announced that the present suits are but the entering wedge to more extensive litigation on the same lines to be prosecuted throughout the country. This will hardly be a surprise to those who have followed the course of the General Electric, as each decline in its stock is the signal for the announcement of an infringement suit of some sort, but these have followed each other recently with such monotonous regularity that the present announcement proved a failure and the stock continued to fall off.

In its previous lamp suits the Trust aimed entirely at the manufacturers of lamps and succeeded in closing the factories of most of its competitors for a few weeks until they could prepare a new style of lamp, which in most cases was promptly done. The influx of new lamps, added to the Trust's defeat in St. Louis, proved the futility of the line of attack which it had adopted and put the coveted lamp monopoly beyond hope of attainment. If this can be considered as success it was certainly dearly bought, as the same competition exists in the lamp business that was met before, to which is added the general enmity of the trade, which the Trust thoroughly earned.

Having failed to secure a monopoly by these measures, the Trust is apparently commencing an attack against private users of lamps to accomplish the same end. It has been evident for some time that the lamp patent was the strongest weapon of the Trust, and the present action is undoubtedly a desperate effort to recover the lost ground which its former suits involved, as there are now many places where the Trust's goods are absolutely excluded where they were previously employed. Moreover such an action cannot be of any financial advantage to the General Electric, as, even if it secures the injunctions asked for, this will not secure the custom of the defendants, which is practically demanded, so long as any other lamp can be bought.

The managers of the Trust in attempting to create a monopoly have, to use a homely but expressive phrase, bitten off more than they can chew, and in view of the short remaining life of the patent upon which it chiefly relied for support, it is not probable that these infringement suits will be brought to trial even if the Trust itself, contrary to expectations, should outlive this short period.

* * *

WE'RE laughin'
At Coffin.

* * *

THE indicted publisher of ELECTRICITY extends his profound sympathy to the indicted President of the General Electric Company.

* * *

A FOOLISH correspondent asks us : Why was not Mr. S. D. Greene indicted for conspiracy along with Mr. Coffin and Mr. Clark ? To which we reply: Why was not our office boy indicted for libel ?

* * *

WE ARE enabled to state, with positive information on the subject, that papers have already been prepared by counsel of the General Electric Company in some very important patent litigation soon to be begun.

A New Insulating Material.

A new insulating material, bearing the name of "Stabilit," has been tested by the Electrical Company, Limited, and the results having proved satisfactory it is now being brought into commerce. This material, which has for some time past been used in the insulation of armatures and magnet and transformer coils, is made in plates, bars and tubes, or in any desired form, in red or grey-black color. It can be turned, bored and polished more easily than indiarubber or vulcanized fiber. It is free from acidiferous or corroding substances, and does therefore not attack metal, and is consequently considered better than any material for the insulation of commutators, magnet coils, switches, etc. After four weeks' exposure to a damp atmosphere, stabilit showed no alteration in weight or in its insulation resistance, and after being boiled for twelve hours no increase in weight was noticed. Stabilit, the specific weight of which is 1·6, is not attacked by muriatic acid or dilute sulphuric acid, and is therefore suitable for accumulator cells and battery jars, as experiments have shown. In the course of tests made to determine the usefulness of stabilit for high tension insulation, plates of 0·7 mm. in thickness were not pierced or broken at 5,000 volts.

Mr. Coffin Indicted for Conspiracy.

The Grand Jury Find True Bills Against All of the Accused Men in the Westinghouse Blue-Print Case.

The Grand Jury at Pittsburg on June 7 found true bills for conspiracy against the following officials of the General Electric Company: C. A. Coffin, president; W. J. Clarke, manager of the railway department ; Milton H. Hamilton, E. W. Rice and H. W. Knight.

True bills were also found against Morris W. Mead, superintendent of the Bureau of Electricity, for conspiracy, and against C. Christian, John Butler and Frank Carey, former employes of the Westinghouse Company, for conspiracy and larceny.

Mr. W. D. Niles, counsel for the General Electric Company at Boston, is quoted as follows in the Boston *Herald :*

"I know absolutely nothing about these indictments, except what I have read in the newspapers. Some of the Westinghouse officials are very persistent, but I cannot believe they have a scintilla of honest evidence implicating any of the officials here.

"As to the proceedings here we have entered our appearance in the Supreme Court for the Thomson-Houston Company and for each of the officials named in the bill, but have not filed an answer on account of other engagements. We are allowed thirty days from June 5 in which to answer. The bill is very long, and each allegation must be specifically answered."

At Harrisburg, on June 10, the matter of issuing requisition papers for the indicted men came up before Gov. Pattison. The General Electric Company were represented by counsel who were there to oppose the granting of such papers for Messrs. Coffin, Rice and Knight. Counsel for the Westinghouse Company asked for the requisition of Messrs. Clark and Hamilton only, as they were in the State of Pennsylvania at the time of the alleged conspiracy. There was no opposition to the latter request, and the papers were accordingly issued by Gov. Pattison.

Competition for the New York Edison Company.

A Healthy Rival in the Field.

Siemens & Halske Apparatus to be Used.

It has leaked out that there will soon be smart competition in the matter of incandescent lighting in New York City.

The New York Light, Heat and Power Company, whose offices are in the Excelsior Building in Gold street, near Fulton, has purchased apparatus from Siemens & Halske which is now on its way from Berlin, and the company expects to be ready for business early in July.

The franchise under which the company is operating is the one originally granted to the old Daft Company in the early eighties, and in which there appear to be no flaws.

The wires are already laid from Houston street to the Battery.

The New York Light, Heat and Power Company is strong financially, and will, it is said, make rapid extensions of its service mains. The company will also make a feature of the supply of power for motor work.

General Electric.

What is Said of it Nowadays.

What Rot.

(From the Wall Street Daily News.)

One of the news agencies issued the following yesterday:

"We have authority to state that a director and a large holder of General Electric stock has not sold a share during the decline from par."

Isn't this the silliest kind of bull guff? Now, who under the sun cares whether one solitary "director and a large holder" has sold his stock or not. Is he the only individual in the company, that the fact [?] of his not having sold out has to be recorded, particularly when he is either afraid or ashamed to have his name mentioned? All this kind of slush is a waste of ink and paper as it accomplishes nothing. The fact is not disputed that the company had to and did sell its gilt-edged treasury stocks; that the price declined from 114⅛ to 58 within a few weeks; that the stock though paying 8 per cent. could not and does not find support in the market, and that its largest, most influential and richest stockholders have sold out, or very much reduced their holdings in the company, and invested the proceeds in securities of other companies paying a much less return. To tell what one man did or did not do simply shows to what straits the manipulators have been driven.

Business is Booming.

The Treasury is Full to Overflowing.

(From the Cincinnati Times-Star.)

Judging by the present business of the General Electric Company, the cry of tight money and dull trade has not yet struck them to any appreciable extent.

They have recently concluded contracts for the building of three 750 h. p. generators for the Cincinnati Street Railway. They have also sold one 750 h. p. generator to Toledo, Ohio; two 750 h. p. generators to Louisville, Ky.; two 750 h.p. generators to Cleveland, Ohio—besides having sold Louisville 65 cars. They have on hand orders for the construction of a number of electric railways and power plants.

The company's financial condition is in good shape. They have money enough in its treasury to pay all expenses and dividends up to and including September, should they not receive a cent from their customers before that time, and when we say that they have in their employ some ten thousand men it will give an idea of their present financial standing. We understand that they have recently concluded contracts for the Brooklyn Traction Company of Brooklyn, N. Y., amounting to $5,000,000; New Orleans, $3,000,000; West End Street Railway, Boston, $1,500,000; besides large contracts in the following cities: Dayton, Cleveland, Toledo, O.; Louisville, Ky.; Buffalo, Syracuse and Albany, N. Y., and many other large contracts in the West and South—in no way including the foreign trade.

An Electrically Equipped Dwelling House.

The *Herald* furnishes the following description of the electrical equipment of the home of Mr. George Foster Peabody in Brooklyn, N. Y., in which all the heating, cooking and lighting are done by the aid of electricity:

To heat a house by electricity nowadays requires no more labor than to equip a habitation with electric lights. All that is necessary is to tap the regular electric mains and wire the house in the same form as for light, the only difference being that the terminals lead to heaters instead of incandescent or arc lights.

In the case of this Brooklyn dwelling a separate circuit is used for the heating, cooking and lighting, so as to determine the amount of current used for each service. Starting from the switchboard, to which all branches lead, and passing into the cellar, the ordinary hot air furnace is found there, but its occupation as a coal consumer and heater is gone, for from the furnace cold air box leads one large main pipe in which is placed an electric heater, then from this main branches start in each of which is also placed an electric heater, the idea being to heat the cold air in the main pipe to a certain degree and then superheat it in the separate pipes.

In mild weather the main heater suffices, but in colder times all the auxiliary heaters are required. A constant circulation of air is kept in the pipes by an electric fan placed in the cold air box, thus insuring a steady supply of fresh air. Even with a winter as rigorous as the last one not a shovelful of coal has been used in the house during the entire season.

Though nearly all of the heating is done through the old furnace pipes, thus entailing no extra expense for running wires, other heating accessories are used in some of the rooms. This only needs a peculiar form of electric radiator and the wires leading thereto. The heat given out is the mildest, most wholesome and most enjoyable of all heats, and when it is no longer required, by simply turning a switch all expense is stopped.

But it is in the kitchen where electricity will probably be mostly appreciated by the housewife. In this electric house every morsel of food that requires cooking is cooked by electricity. The kitchen range is still there, but instead of the old time roasting fire an electric broiler, oven and water heaters are placed upon the stove, none of which differ particularly in shape or form from ordinary kitchen utensils, with the exception of the small heater placed in each one.

Electricity's services are required to heat every drop of water used in the house. This necessitated no great change, nothing more than the insertion of heaters in the old boilers and removing the range pipes. Another feature of domestic appliances where electricity is aptly employed is ironing, but from the insulated wire which is attached to an electric flatiron no one would know it by outward appearances from the common type, though here again a little electric heater is stowed away. This form of flatiron lightens the burdens of the laundress and saves both time and steps in avoiding the need of reheating irons. The heat in the flatirons is always at an even temperature, with a consequent improvement in the work.

The house is, of course, lighted throughout with electricity in the most artistic manner, and no other form of artificial light is allowed to penetrate the grounds. Whenever any motive power is required, as in running sewing machines or ventilating fans, etc., the electric motor is called into action and does its work noiselessly and most efficiently.

Legal Notes.

A supplemental bill of complaint has been filed by the Accumulator Company of Newark, N. J., in its case against the Consolidated Electric Storage Company in the United States Circuit Court at Trenton.

The complainants obtained a preliminary injunction against the defendants in January last. They requested the latter to return the profits and gains made by infringing, but have not been recompensed. They now ask that the defendants be made to appear and answer to the bill of complaint They also ask for a provisional or preliminary injunction.

The Edison Illuminating Company of New York recently brought suit against one of its customers for $180. The customer had offered the company $30 in settlement of his bill, and denied that he had received the amount of light charged for. A verdict was rendered in favor of the defendant.

In the Supreme Court at Trenton, N. J., on the 8th inst., Justice Depue rendered a decision defining the powers of the New Jersey Electrical Subway Commission. The case was founded on a resolution of the Subway Commission which gave the right to erect poles and string wires. The Supreme Court declares that the Subway Commission cannot grant any franchises, their functions being simply supervisory over the exercise of franchises derived from other legislative authorities.

A suit has been filed by the McKeesport (Pa.) Telephone Company, Limited, for use of the McKeesport Telephone Company, against the Shaver Company of New Jersey, to recover $5,500. The defendant, it is alleged, was to build and furnish an electric telephone exchange, which was to be in working order by March 7, 1893. Money was advanced by the plaintiff company. The contract is not yet completed. It is further alleged that the American Bell Telephone Company has obtained an injunction against the Shaver Company, restraining it from using certain patents.

The Western Electric Company of Chicago has filed with the Clerk of the United States Circuit Court in Utica complaints in three actions against the Fire Alarm Telegraph Company. The complainant alleges that the defendant has infringed upon a patent issued to Thomas H. Watson in April, 1878, on a telephone call signal apparatus; also upon a patent issued to Ezra T. Gilliland, of Indianapolis, in July, 1880, on a magnetic generator for telephone signals, and also upon a patent on a polarized armature for electric bells, the original patent being granted to Thomas H. Watson, of Boston, in December, 1878.

The Ohio Valley and West Virginia Coal Company has begun a suit for damages against the Cleveland, O., General Electric Company, for some high-handed proceedings in tearing down buildings and sheds on premises under lease to the coal company. The General Electric Company recently purchased the property for the erection of a new power house.

The Usher Battery Suit.

In his testimony in the Brush suit against the Milford and Hopedale Street Railway Company for alleged infringement of the Brush patents in using the Usher battery, Prof. Trowbridge said in speaking of the Usher battery: "It has a very remarkable efficiency, and has developed certain novel properties which seem to indicate that its mode of operation is peculiar to itself. . . . It improved under rates of discharge which would speedily ruin a Faure or a Brush cell. I have often discharged an Usher cell at the rate of 150 amperes and have found the cell improved by this treatment. I have completely exhausted a Brush cell of the same weight as an Usher cell in forty-five minutes by discharging at a sixty-ampere rate. The Usher cell maintained this rate of discharge for one hour and a half and then was not exhausted. . . . The great question now is, how much power will the battery return in comparison with the power put into the battery. When I found that they would exert the power necessary to propel a car from Bowdoin Square to Harvard Square with a loss of only 20 to 25 per cent. of the power used to charge the cell, and I found after using the cells for six months that they showed no sign of diminishing capacity, I saw that the Usher cell was a radical departure from the Brush cell. At high rates of discharge, which are the only practical and useful rates of discharge for car traction purposes, there is no possibility of comparing an Usher cell with a Brush cell."

Current Items.

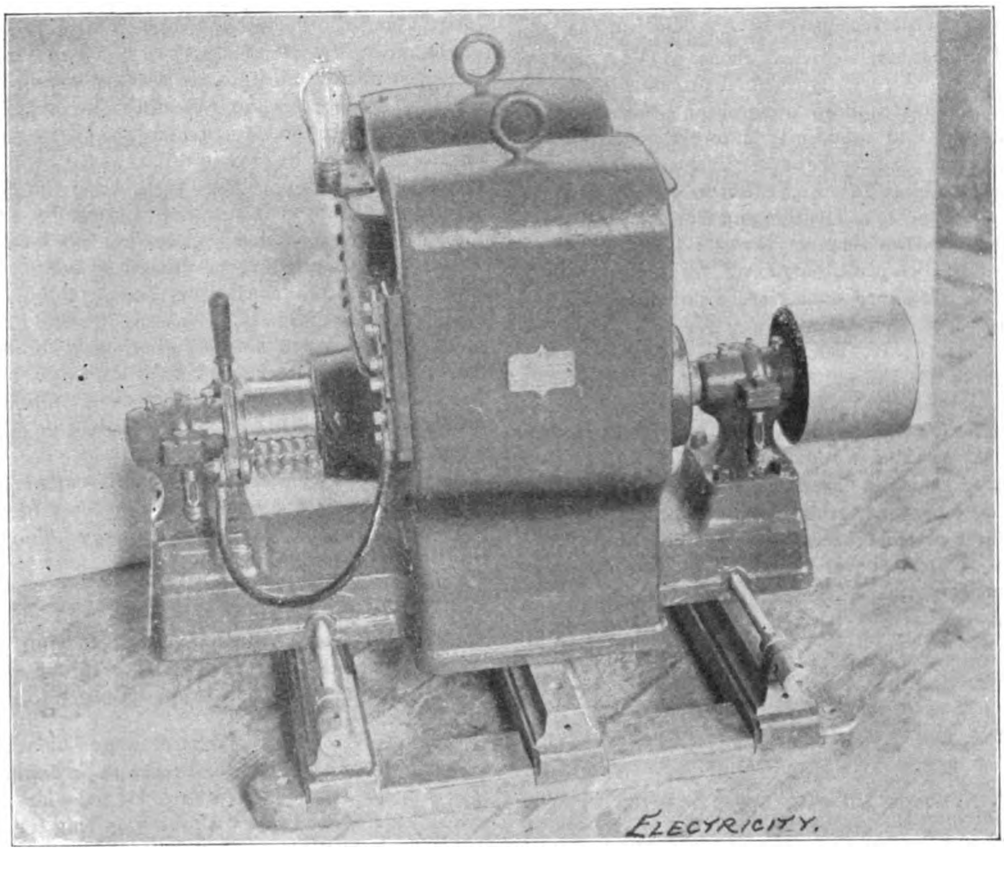
The proprietor of a laundry at Lauter, in Germany, has adopted electric heating for 60 of the flatirons used in his establishment. A 40 H. P. dynamo provides current for heating, for lighting, and for driving motors for the various washing and wringing and mangling machines. The core of the flatirons is formed of asbestos in which platinum wires are imbedded which are made incandescent by the current. As current is cheap and expense is saved when the irons are not in use, the application is not found expensive, while the cleanliness and convenience are beyond dispute.

It is said that a German firm in Munich is making a business of renewing the filaments of incandescent lamps by a process which costs 25 per cent. less than the operation of making new lamps. An opening is made in the glass globe at the upper end. The old filament is removed and a new one inserted, the latter being secured to the leading-in wires by means of a new cement, which becomes a conductor when a current is passed through it. The lamp is sealed and exhausted as usual.

The Muncie "Iron Clad" Machines.

The Muncie Electric Works, recently established at Muncie, Ind., has just put upon the market its new "Iron Clad," which is shown in the following illustration and which has been adopted by this company as its standard type for constant potential dynamos and motors.

The magnet consists of but one casting bringing the magnetic leakage down to a minimum by doing away with all joints. There is but one field coil, which is wound in three sections, so that in case of accident it would rarely be necessary to replace more than one. The armature is placed below the field coil, admitting of the lowest possible center of gravity and obviating the injurious effects from vibration. The brushholders are of a new and simple design and are arranged so that either holder complete can be removed without disturbing the yoke, or in case it should be necessary to replace one or more of the carbons, of which there are five to each holder, any one of the separate sockets containing the carbons can be removed and replaced without interfering with the operation of the machine. The boxes are self-oiling and aligning, with phosphor-bronze bearings and are fitted with sight oil gauges. The shaft is of the best grade of steel and is extra large in diameter. The armature is drum-wound and is of very low resistance, and the commutator is of tempered copper, thoroughly insulated with mica.



THE MUNCIE "IRON CLAD" DYNAMO.

The connection boards are of marbleized slate arranged in the simplest manner possible, and the rheostats have metal frames with slate bases and lava insulators, making them thoroughly fire-proof. The machine as a whole has been designed with the utmost care, both mechanically and electrically, is simple and efficient, and runs at a slow speed. The cut shown is of an 8½ K. W. machine, which has given an efficiency of 90 per cent. on actual tests. Its speed is 1,100 revolutions per minute. It is designed so as to permit the commutator to run entirely free from sparking, there being no lead of brushes between no load and full load. The company is now in full operation, manufacturing all sizes from ½ to 50 K. W. machines.

Pocket-Books.

How is it that compilers of pocket-books do not compile what is wanted? There is, as yet, no absolutely satisfactory electrical engineer's pocket-book, though several authorities have tried their hands at the production of such a work: these usually containing both too much and not enough, and the information is not always that which is really wanted when it is given. When all is considered, what are the requirements? Is it necessary for the pocket-book to go into the waistcoat, like Prof. Thompson's. Should it really be a pocket-book at all? Should it contain electrical information only, or mechanical engineering as well? All these are questions for the engineers themselves to decide; but as very few electrical engineers, if asked, confess to having found the pocket-book they want, it is evident an ideal book is yet to be made. One well-known electrical engineer gives it as his opinion that if one wants a useful pocket-book one must go to Germany; he swears by Hütte's "Pocket-book of General Engineering," published by the Verein Hütte, which gives succinctly both theory and formulæ on usual engineering matters, with a chapter on electrical subjects. As work goes nowadays, the questions of general engineering—buildings, girders, engines, pulleys, belting, rails and traction—play quite as important a part in electrical work as purely electrical problems. An electrical engineer's pocket-book should contain formulæ for dealing with these; it should avoid redundant matter; it should not aim to teach, but to remind; and it should contain the formulæ in their most workable form.—*Electrical Engineer*, London.

Insulating Wire by Paper.

This paper, which is specially made, is thoroughly cured before being used. The rolls are mounted on machines, and are cut into strips by circular shears, which leave the paper resembling "ticker tape." The spools of paper are then placed on mandrels in the covering machines, and as the wire feeds through the paper is laid on in overlapping spirals at the rate of from 60 to 500 revolutions of the mechanism per minute. The wire is then passed through dies, which materially increase the tightness and compactness of the insulation. The next step is the winding of the wire on iron reels, which are placed in drying ovens that have a temperature of 250 degs. Fahrenheit. This expels all moisture, and the wire is suddenly plunged in a special secret compound and for some time subjected to a stewing process at a temperature of about 275 degs. The wires in due course go from the tanks to the braiding or leading department, where they are finished. Although paper-insulated wire is used largely in telephone work, it has been found very effective and reliable with high potential currents, even up to 10,000 volts.—*Electricity*, London.

The Johns Hopkins Electrical Engineering Course.

We have received a prospectus from this university calling attention to the course in electrical engineering, which has been established with the object of preparing students to keep pace with the latest advances in electricity, and consists of both theoretical and practical work.

The course extends through two years and is primarily intended for graduates, but special students are admitted on passing certain examinations.

The instruction in electricity includes lectures on theoretical and applied electricity, with constant laboratory work. The lectures aim to give a clear working-knowledge of the science, while in the laboratory the student receives what help and instruction he may need, yet at the same time he is taught to depend upon and think for himself, and is given every encouragement to undertake original work.

Laboratory Work.—The students are expected to spend all of their available time in laboratory work, and the minimum time allowed is nine hours per week.

During the first year the fundamental measurements in electricity and magnetism are made, and also tests of dynamos, motors, incandescent and arc lamps, etc. The work is largely individual and the character and grade of the work given to the student is determined by his qualifications.

During the second year more advanced work is done and the students are given original problems to work out in the laboratory, and research work is engaged in. Tests of steam engines and boilers, experiments and investigations in alternating currents and transmission plants form an important part of the work. During the latter half of the year complete tests of electric cars and central stations are made and the results carefully worked out.

The allied subjects of steam and hydraulic engineering, machine design and mechanical drawing are also included in this course.

The instruction is given by Dr. Louis Duncan, Mr. Herman S. Hering, M. E., and Mr. Francis Head, M. E.

The Electric Tramway in its Social Bearing.

It does not seen unlikely that the electric tramway will be the means of revolutionizing domestic life in our Colonies, and of considerably modifying several of the more general classes of business. Toronto, Canada, has to-day twenty-seven miles of shop fronts, but the tendency is for many of the smaller shops on principal thoroughfares, such as King and Yonge streets, to revert to residential purposes, they having found their occupation gone. The principal cause at work tending to bring about this change is the partial solution of the rapid transit problem by electric tramways. By such means the residents in the outlying districts of the city can be transported to the business centre in a few minutes. The larger down town establishments are benefiting by this to the detriment of the smaller concerns on the less important street in the suburbs. The lesser influence is that of the "store," in which the business of almost every class is congregated, and where comfort is assisted by electric lighting, electric lifts and general sumptuousness. These changes are most seriously affecting the value of a large amount of property now used for business purposes, and it may not be long before similar conditions impress themselves upon our communities at home.—*Electrical Review*, London.

Detroit Electrical Works.

Prospects of a Reorganization.

It is reported from Detroit that arrangements have been practically concluded for a thorough reorganization of the Detroit Electrical Works, a deal having been made with an Eastern syndicate who will put in plenty of capital.

There is no reason why this company, under competent management, should not be a thoroughly prosperous concern. They have an efficient apparatus, on a par with the best, and nothing but gross incompetency could have reduced the company to its present condition.

Mr. L. E. Myers, of the Chicago office, has done splendid work, and is capable of doing better still properly backed by good management at the home office.

The first step after reorganization should be to again secure the services of Mr. Frank Rae, who made the apparatus all that it was at its best, and who presumably knows more about it than any one else.

John F. Schaefer Arrested.

John F. Schaefer, who has of late been superintendent of the Illinois Lamp Company of Chicago, was arrested on June 5, charged with stealing 115 incandescent lamps from that company. The case was postponed until June 13, Schaefer being released on $300 bail.

We are advised by a personal letter from Chicago that Schaefer, at the time he was arrested, was trying to sell a patent (the property of the Illinois Lamp Company) to the General Electric Company.

No Compromise.

It has been erroneously stated in the daily press that a compromise has been effected in the matter of the infringement suits brought by the General Electric Company against various users of Sawyer-Man lamps in this city. There has been no compromise, but a postponement of the hearing, which was made necessary by the illness of Mr. Edmund Wetmore and Leonard E. Curtis, of counsel for the Westinghouse Company.

The McKeesport Case.

Mr. E. L. Porter, who was appointed to report a schedule of distribution of the proceeds of the sale of the McKeesport Edison station under the receivership of Mr. S. A. Duncan, has filed his report. The case presented some unique features, and is of more than passing interest to Edison licensees. Mr. Porter gives the following summary of the difficulties and their favorable outcome:

> There were originally two factions, a local faction and a faction of the parent Edison Company. At the annual election in 1890 the Edison faction attempted to make a change in the directory of the company. The local faction avoided this by bolting the meeting and preventing a quorum, thus holding over until the election in 1891 when the Edison Company got control. During this time the company had contracted a larger indebtedness, and when the Edison faction got hold it was deeply involved in debt. The creditors pressed the company and a number of them got judgments, some by confession and others by default, and in February, 1892, T. L. White and others of the local faction brought the present suit, alleging mismanagement and asking for the appointment of a receiver. S. A. Duncan was appointed receiver and eventually a sale was directed. The local stockholders then tried to get control of the outstanding indebtedness and arrange for bonding the company to take care of it. T. L. White paid and had assigned to himself as trustee $25,000 of the indebtedness, but the board of directors refused to bond the company. The plant of the company was then sold by the receiver and the auditor appointed to report a schedule for the distribution of the funds in his hands arising from the sale.
>
> The auditor shows the total amount in possession of the receiver was $58,549.18. The expenses of the audit, etc., amounted to $1,102.68, leaving for distribution among the creditors $57,446.50. This almost paid the creditors in full. White, as trustee, receives $24,984.64. The other claims are small.

Personal.

Mr. J. Holt Gates, who has been with the Siemens & Halske Company at Chicago for some time, has formed a connection with the Waddell-Entz Company of this city, and will hereafter act as Western agent of the latter company, with temporary offices at 1,122 Monadnock Building, Chicago. The Waddell-Entz Company has established a high reputation, not only for its apparatus, but for straightforward business methods, and we predict that Mr. Gates's new office will be a profitable one for everybody concerned.

Mr. C. A. Daigh has been appointed General Sales Agent of the Siemens & Halske Company to succeed Mr. Gates. Mr. Daigh enjoys a wide acquaintance in the trade, his most recent engagement having been with the National Electric Manufacturing Company of Eau Claire.

The Washington Association.

The leading electrical firms of Washington, D. C., have recently formed an association for establishing a more general and better understanding and unanimity among themselves, and for their mutual benefit. The association was organized last July and is known as the "Association of Electrical Dealers and Contractors." The officers for the ensuing year are: President, C. W. Jordan; vice-president, J. W. Burkett; secretary, C. W. Hessner; treasurer, John R. Calloway. The firms represented are Messrs. Jordan & McLeod, J. W. Burkett & Company, Royce & Mareau, The Washington Construction Company (Pardee and Messner), The Bliss Engineering Company (Bliss and Lewis), John R. Calloway, D. H. Washburn and J. H. Kueling. The association is in a flourishing condition and has already shown to its members that it is a valuable aid to electrical interests in Washington.

The International Maritime Congress.

The second meeting of the International Maritime Congress is to be held at the headquarters of the English Institution of Civil Engineers beginning July 18, 1893.

The first meeting was held in Paris in 1889 at which a permanent organization was effected, with headquarters in Paris, comprising representatives of thirteen European countries.

The following arrangements have been made for the consideration of the various subjects to be brought forward at the London meeting:

1st Section—Harbors; Breakwaters; Protection of Coasts.

2d Section—Docks, and their Equipment.

3d Section—Shipbuilding; Marine Engines; Auxiliary Machinery on board ship.

4th Section—Lighthouses, and their Illumination; Electrical Connection of Lighthouses and Light-ships with the Shore; Fog Signals.

After the London meeting, it is proposed that, in addition to an inspection of the docks along the Thames, visits shall be made to some of the other leading seaports of the kingdom.

Proposed Consolidation in St. Louis.

The Municipal and Missouri Companies Trying to Get Together.

It is reported on very good authority that the Missouri Electric Light and Power Company of St. Louis is to absorb its rival, the Municipal Electric Light and Power Company, and that the companies will be under one management after July 1.

A consolidation of these companies has been talked of for some time. Previous to the decision in the Columbia lamp case it was generally believed the Missouri Company would be the one to sell out, but that decision has put a very different phase on the lighting situation.

It will be remembered that last fall a "local" Edison company was organized in St. Louis with a capital stock of $5,000.

But it seems that this company is not a factor since Judge Hallett's decision.

World's Fair Notes.

The increased number of visitors during the last week has made the few exhibitors who were behind in their work realize what they were losing in the way of advertising by not having their exhibits in shape for inspection. The average attendance during the week reached nearly 75,000. With the exception of a very few exhibits it may be said that the Electricity Building is ready to be inspected and the attendance of any one need not be delayed for fear that he will not see it all. To judge from the crowds to be found in the Electricity Building and the remarks heard about the Park, the electrical display is one of the most attractive features of the Exposition. Very few of the buildings are without some novel form of its application. Besides the ordinary uses of lighting and furnishing power, its novel applications may be seen in different parts of the Electricity Building. The Wellington Catering Company has used electricity indirectly as a means to wash dishes, while another concessionary has applied it to blacking boots and shoes. The Carpenter Electric Heating Company, occupying a portion of the Ansonia Electric Company's booth, has a colored gentleman showing the good uses to which electricity can be put to in the kitchen. Every day about the noon hour a dinner is prepared in the electric oven or on other cooking utensils.

Another electrical device which is attracting the attention of the visitors is exhibited by the National Engraving Machine Company. The exhibit shows the application of electricity to engraving on metal, stone and wood.

In honor of the visit of the Princess Eulalia of Spain to the Exposition an extra decoration was added to the Edison tower. It consisted of a number of incandescent lamps arranged to read "Eulalia."

Professor Grey has at last arranged his much sought for exhibit of telautograph machines. Few people visiting the Fair during the last few weeks have gone away without inquiring for the machine that writes by electricity. The professor has nine machines on exhibition in his booth and a number of young men are on hand to show them in actual operation.

The Chicago Central Phonograph Company, in conjunction with the Long Distance Telephone Company, have arranged a novel entertainment for next Saturday evening. A specially constructed transmitter is to be attached to a phonograph on the Chicago end of the Chicago-New York wire and guests in New York are to be entertained by music and songs furnished by the phonograph located in the Electricity Building.

The Westinghouse Electric Company is engaged in decorating the south wall of the Electricity Building with a large picture of Columbus surrounded by the name of the company spelled out with groups of incandescent lamps.

The movable sidewalk, which is another example of the various applications of the electric current, was set in operation last Saturday. The sidewalk is located on the pier extending into the lake from the north end of the grounds.

A decision was rendered in the United States Court last Thursday which it is thought will effectually close the gates of the Exposition on Sunday. Although the decision was against the wishes of a majority of the exhibitors, it may operate indirectly to show the value of electric lighting, as a large number of people will be compelled to visit the Exposition at night who would otherwise put off their visits until Sunday.

Chicago Notes.

Geo. Cutter is on a trip to Boston and other Eastern cities.

John R. Fletcher, of Dayton, was a visitor in Chicago and at the World's Fair last week.

Geo. J. Percival, the well known electrical engineer of St. Louis, and Fred. Adams, of the Adams Electric Company at the same place, were among the electrical men in the city lately.

Mr. Hess, senior member of the Hess Electrical Company of Des Moines, was in Chicago last week. He is about to move into larger quarters so as to carry a larger stock of electrical goods.

The Western office of Claflin & Kimball, general selling agents for the Novak lamp, has been moved into a suite of offices in the Chamber of Commerce building.

The Star Electric Company report an increasing business since placing their new lamp on the market.

Boston Notes.

A big mortgage was recorded in Lawrence, Mass., last Monday, the amount being for no less than $1,900,000, the trustee being the American Loan and Trust Company of Boston. The deed was filed by the Lowell, Lawrence and Haverhill Street Railway Company to secure the issue of 5 per cent. gold bonds for thirty years.

The Rapid Transit Bill for Boston has at last been passed to be engrossed by the State Legislature so weighted down by conditions that the bill is practically useless, and it is very doubtful indeed if any action will be taken under such a bill when it has been finally passed. So after long and weary delay, the expenditure of a large sum of money, and the taking of almost endless testimony, the entire movement for improving city and suburban travel in and around Boston is as far off as ever.

The workmen employed by the General Electric Company in their Lynn factories began work under their new time schedule last Monday, and, now the excitement incident to the recent agitation for a reduction of four hours per week has subsided, they all appear fairly well satisfied.

There is a bill before the Massachusetts Legislature for enforcing the burial of electric wires throughout the city of Boston which stands a fair show of being deprived of all its prospective usefulness, if it ever had any, by reason of a misunderstanding as to purposes of such a bill. High potential wires are to go underground if the bill passes, while low potential wires are not considered of sufficient importance to need a change. As a fact, however, the number of high potential overhead wires is quite insignificant, while the low potential wires can be counted by thousands. If anything is to be done in that direction, it should be done thoroughly or not at all.

Last Friday evening a pleasant gathering took place at the Thomson Scientific Club House in Lynn, the occasion being a "send off" to Mr. John T. Morrow, one of the chief engineers in the factories, who has accepted an appointment out West. There was a large and jolly crowd of electricians who did justice to the excellent supper, each one contributing either song or speech towards the evening's entertainment. Mr. Morrow has accepted an appointment with the Boston and Montana Mining Company at Great Falls, Montana.

Mr. George F. Curtis, who is at the head of the Bureau of Information in the General Electric Company, has just returned from a three months' vacation in the Bahama Islands. Mr. Curtis's health is greatly improved by his trip South.

The American Railroad Improvement Company, having its principal offices in the New York Life Insurance Building, 95 Milk street, Boston, is the name of a corporation with $1,000,000 capital that has been formed for the purpose of acquiring, operating, constructing and dealing in street railways, electric light, steam and water power plants and properties throughout the New England States. The company has already purchased a well established business of the kind and owns a number of valuable patents for various railway devices, all of which will be worked in connection with their business. Mr. George A. Bratey, a well-known electrical constructing engineer, who by his energy and skill has achieved great success, is treasurer and general manager of this big company.

Dr. George L. Austin, proprietor and editor of the two New England journals, *Practical Electricity* and *Electricity and Railroading*, succumbed to an attack of pneumonia at his home in Melrose a few days ago. Dr. Austin was as well known as any man in the electrical business.

General News.

What is Going on in the Electrical World.

Rockville, Conn.—The council has voted to appropriate $2,500 for an electric fire alarm system.

Sing Sing, N. Y.—The Ossining electric road, which lies in the principal streets of Sing Sing, has been opened for traffic.

Newburgh, N. Y.—There is some talk here of constructing a trolley railroad from Newburgh to Walden with an extension to Goshen.

Norwalk, Ohio.—The plant of the Norwalk Incandescent Light and Power Company is advertised to be sold at auction by the assignees.

Brooklyn, N. Y.—The trolley is now in operation on the Fulton street line of the Brooklyn City Railroad from Fulton Ferry to East New York.

Auburn, N. Y.—The contract for lighting the city for two years has been awarded divisionally to the Electric Light and Gas Light Companies.

Bridgeport, Conn.—The Bridgeport Horse Railroad Company will, it is said, shortly establish an electric plant here and convert their road into an electric system

Abbeville, La.—It is proposed to organize a telephone company to connect Abbeville and the surrounding towns by wires, extending the lines as far as Lake Charles.

Rhinecliff, N. Y.—A project is on foot to establish a trolley line between the N. Y. Central Railroad station here and the village of Rhinebeck, two and a half miles distant.

New Haven, Conn.—The State street line is making good progress in its electrical equipment. The Whitney avenue line, it is thought, will also be granted permission to use electricity.

Washington, Pa.—The Electric Light and Power Company having refused to furnish power any longer to the Electric Street Railway Company, the latter has suspended the running of its cars.

New York.—The General Electric Company has declared a dividend of 3½ per cent. payable July 1 to the holders of preferred stock at the close of business June 19. Transfer books close July 3.

Jamestown, N.Y.—The Jamestown Consumers' Arc Light and Power Company, now being organized, proposes to utilize the water power known as the Dexterville dam in the generation of electricity.

Bridgeton, N. J.—J. P. Newbold and Walter Bacon, residents of this place, have been getting signatures of property holders along the route between Bridgeton, Fairton and Cedarville for a proposed electric railroad.

Lockport, N. Y.—It is understood that Lockport is to be connected to Buffalo by means of the Buffalo and Williamsville Electric Railway, a branch of which is to be run to Swarmsville and thence down the Transit road to Lockport.

Edgewater, Staten Island.—The trustees have requested the Electric Power Company to continue lighting the streets of the village until such time as a contract could be made, and the clerk was directed to readvertise for bids.

Springfield, Ohio.—Work on the extension of the Ohio Southern Railway from Springfield to Lima is being hurried through day and night. upectric light is used at night, the plant being set El in advance of the construction parties.

Pittsfield, Mass.—The building in which were the insulation and drying rooms of the Stanley Electric Manufacturing Company was destroyed by fire last week. The damage was about $7,000; insured. The company will rebuild at once.

New Orleans, La.—A meeting of the stockholders of the St. Charles Street Railroad Company is to be held on July 10 to vote on an increase of the capital stock to $1,000,000, to provide funds to equip the various lines of the company with electricity.

Jersey City.—Mayor Wanser has signed the ordinance granting the Jersey City, Hoboken and Rutherford Electric Railway Company the right to run its lines within the city limits, the company having bound itself to pay to the city five per cent. on its gross receipts.

Westchester, N. Y.—The Westchester Electric Company has obtained permission from the State Board of Railroad Commissioners to use the electric trolley power on the recently acquired roads in South Mount Vernon, East Chester, Pelham, New Rochelle and Rye.

Augusta, Ga.—Work on the Richmond County Belt Line has been stopped. The *Chronicle* states that liens have been filed against the road amounting to over $35,000, among which is one of $12,000 by the firm of J. G. White & Co., of New York, and one of $20,000 by the Pennsylvania Steel Company.

Jamaica, L. I., N.Y.—The town board has resolved to advertise for bids for lighting the Woodhaven district with electric lights. The bids will be opened at 10 A. M. on July 7. Eighty arc lights are called for in a district which embraces Woodhaven, Ozone Park, Brooklyn Hills and Union Course.

Richmond, Va.—At a recent meeting of the stockholders of the Johnston Safe Automatic Electric Company, the old board of directors was re-elected, as follows: Colonel William D. Rice, Major A. W. Garber, Colonel Tazewell Ellett, F. B. Jacobs, C. E. Boiling, John Rutherford and Langstaff Johnston.

Rahway, N. J.—A beginning was made last week in the construction of the Rahway Electric Railway, which will connect Rahway with Woodbridge, Papiac (Boynton Beach) and Carteret. The road will be about seven miles long, trolley system, and power will be furnished by the Rahway Electric Light and Power Company.

Woodbury, Conn.—The Woodbury electric road charter has been secured and its limitations embrace a line from that place to Washington. The line goes from Woodbury to a point near the New England railroad station in Southbury, a distance of four miles; from that place to Southford, a distance of three miles, and on to Washington.

Charleston, S. C.—At the annual meeting of the Charleston Light and Power Company, held last week, the following officers were elected: George B. Edwards, president; B. T. Burt, secretary and treasurer; directors, George B. Edwards, Samuel G. Stoney, G. E. Gibbon, B.T. Burt and C. A. Coffin.

Frederick, Md.—The organization of the Frederick and Middletown Electric Railway Company has been completed by the election of the following officers: Loren N. Downs of New York, president; Dr. Upton A. Sharretts of Frederick, vice-president; Edgar L Miller of Frederick, secretary; George William Smith of Frederick, treasurer, and C. V. S. Levy of Frederick, attorney.

Hartford, Conn.—Among the acts passed lately by the Connecticut Senate was one empowering the Ponemah Mills Company of Tariffville, manufacturers of fine cotton goods, to sell electricity in Norwich, Lisbon, Franklin, and neighboring places. This is the first instance so far as known where a cotton manufacturing firm has been permitted to engage in the manufacture and distribution of electricity.

Omaha, Neb.—City Electrician Cowgill has photometrically tested some of the street arc lights furnished by the Thomson-Houston Company and found them varying from the 2,000 candle-power required by the contract, in one instance minus 1,000 C. P., in another 1,400 C. P. Mr. Cowgill has full confidence in the accuracy of his instrument, and will continue his tests.

Morrisville, Pa.—A trolley road to pass through lower Bucks County is proposed. The route runs from Morrisville, passing through Fallsington, Langhorne, Neshaminy Falls, Trappe, Byberry Point, Bustleton, Frankford, and thence to Sixty-third and Market streets, Philadelphia. The charter name of the company is the Suburban Railroad Company.

Austin, Tex.—The great dam across the Colorado River is completed. The length of the dam is 1,150 feet; it is 66 feet high, 60 feet broad at the base and 16 feet at the crest. The purpose of the dam is to furnish a water supply and power for the electric light system of Austin. Besides accomplishing these purposes, 14,000 horse power has been developed, which will be disposed of to manufacturers at nominal cost. The cost of the dam was over $600,000.

Wilmerding, Pa.—The Pennsylvania Railroad Company has bought a site for a new station at this place and will stop all trains here but the limited as soon as the McKeesport and Wilmerding Electric Railway is completed, which will be in a short time. By October it is thought that an electric line will extend from McKeesport to Pittsburg, passing through Wilmerding.

Long Branch, N. J.—The scheme to connect a number of pleasure resorts from Pleasure Bay to Point Pleasant, a distance of twenty-five miles, is backed by several capitalists and railroad men, among them being J. C. Shaffer, president of the Seashore Electric Railway of Asbury Park and a large stock owner in the Indianapolis Street Railway. The company have received letters asking them to extend the road to Trenton and Camden.

Charleston, W Va.—The Kanawha Electric Street Railway Company has asked council for a franchise to operate an electric railway on streets in the city not now in use by the Street Railway Company. The Kanawha Company agrees to put up a forfeit and to begin work in thirty days, to complete one mile within six months and six miles within three years, and to pay the city $500 for each mile of railway constructed.

Gettysburg, Pa.—The War Department at Washington has compelled the company who were running a trolley line through portions of the battlefield to remove their tracks and directed them to fill in and resod the cuts made through the portions of the field that the Government has decided must be held intact. The road will be constructed, but only on such routes as may be determined by the Battlefield Commission.

Indianapolis, Ind.—The *Journal* says "the indications are that outside capital cannot be secured for railway enterprises in Indiana. A prominent railway man says: 'Capital is chary in regard to railway investments in this State, and the feeling is due to almost complete confiscation by unjust and excessive taxation of railways, and railway construction will have a decided check until there is a change in the manner of taxing such property.'"

Cumberland, Md.—The Cumberland Electric Railway Company has purchased and put on one of its cars a new motor of the Westinghouse system. The *News* says "the new motor is fifty horse power and capable of high speed. There is an absence of the ordinary noise or buzzing, and a ride on the car is smooth and delightful. The motor will soon be transferred to a car especially built for it, and in course of time all of the cars on the line will receive the new equipment."

Pottstown, Pa.—The Chester County Electric Railway Company, recently incorporated, intend to build an electric railway from Douglassville to Pottstown and Parker Ford, to connect at each end of the road with the Pennsylvania Railroad. The line will be laid on the south side of the Schuylkill, with a branch or river connection across to Pottstown, on a bridge to be built by the company. Other branches, running to Pughtown and probably to West Chester, are also contemplated.

Norristown, Pa.—The Chestnut Hill and Norristown Passenger Railway Company, recently chartered to construct and maintain an electric railway between Philadelphia and Norristown, have filed their acceptance of the ordinance passed by town council on May 16 last, extending to them a trolley franchise over certain streets in the borough of Norristown, and have submitted a bond in the sum of $5,000 as a forfeiture in case the road should not be completed and in operation within fourteen months from the date of the passage of the ordinance.

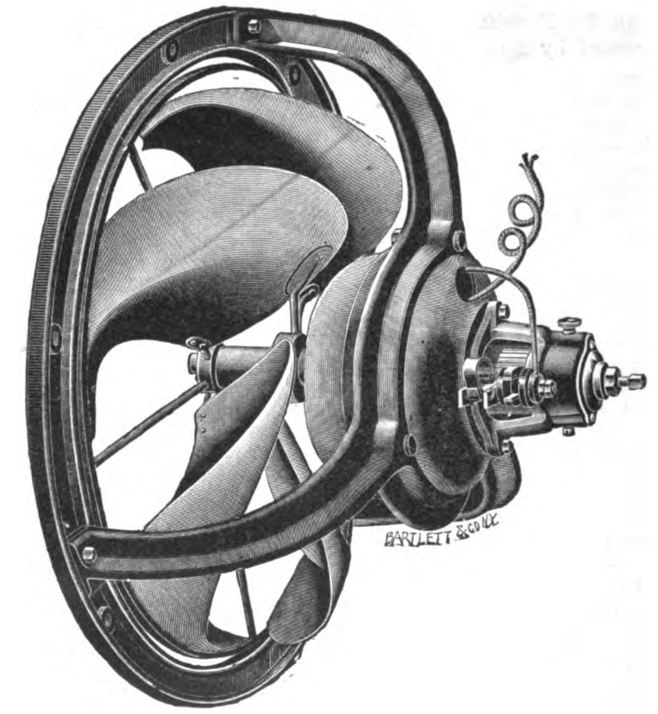
Cleveland, Ohio.—The city council has at last given its sanction to the consolidation of the street railroads comprising the Cleveland Electric Railway Company, the main condition being that "only one fare shall be charged for a continuous ride on or over any of said constituent companies and any other line of any other of said constituent companies within the limits of the city of Cleveland; and passengers on any of such lines paying one fare shall be entitled, without additional or extra charge to be transferred to any other of said lines and have a continuous ride thereon for said single fare." The companies consolidated were formerly the East Cleveland Railroad Company, the Broadway and Newburg Street Railroad Company, the Brooklyn Street Railroad Company and the South Side Street Railroad Company.

Gloversville, N. Y.—The Fonda, Johnstown and Gloversville Railroad and the Cayadutta Electric Railroad are now the property of the same company, the former road having recently been purchased by the Electric Railroad Company. After the purchase a new board of directors was elected, consisting of James S. Burr, W. J. Heacock, Charles W. Judson, A. J. Zimmer, S. H. Shotwell, Gustav Levor and George M. Place, of Gloversville; James P. Argersinger and John G. Ferres, of Johnstown; G. F. Mills, J. L. Hees, of Fonda; Thomas F. Kyne, of Amsterdam, and James Shanahan, of Tribes Hill. The new directors have elected as officers of the road: President, Hon. James Shanahan; vice-president, James P. Argersinger; treasurer, J. L. Hees; secretary, George M. Place. Lawton Caten has been appointed general manager or superintendent in place of R. T. McKeever, resigned. The headquarters of the road will remain at Gloversville.

W. C. Callman & Company.

Messrs. Wm. C. Callman & Company having recently moved their offices to the Electrical Exchange Building, 136 Liberty street, are now carrying a complete line of electrical supplies.

They are having quite a run on the Feldkamp Fans and Motors, and are at present negotiating for the Eastern agency of a well-known Western dynamo and motor house.



BARTLETT &CO NY.

THE LUNDELL EXHAUST FAN OUTFIT.

The Lundell Exhaust Fan Outfit.

We herewith illustrate a new outfit which is a combination of an ordinary exhaust fan directly coupled to a slow speed Lundell motor. The absence of belting and the absolute noiselessness of the outfit is particularly noticeable. An exposition of the adaptability of this outfit for certain places is found in the installation in the restaurant of Busse & Simoni, Delmonico's old place in New street. Guests sitting directly underneath the fan do not notice that it is running. The location of the fan is novel and serves a double purpose. It exhausts the air from both kitchen and restaurant and gives comfort to both guests and chefs. This ventilating outfit is adapted for all places and is a sure means of keeping the air in a pure and wholesome condition. The Lundell Exhaust Fan Outfit is placed on the market by the Interior Conduit and Insulation Company.

Automatic Short Circuit Alarm Bell.

This ingenious and novel device has only lately been devised and owing to its practicability, simplicity, reliability and cheapness will become very popular with the electric fitting trade.

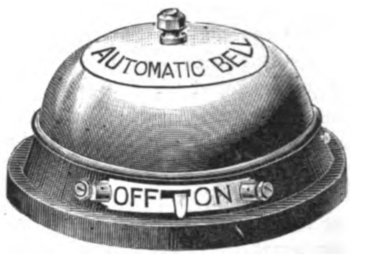
It combines in itself all of the features of the already well-known "Detached Relay" with local bell and battery, without the expense of the latter two, and further acts not only to give an alarm when a short circuit occurs, but also to interpose a resistance in the battery circuit, preventing deterioration of the battery while on short circuit within practical limits.

The cut shows its exterior appearance, there being on the base, besides the four inch gong, two binding posts, a switch and an adjusting screw (shown at the right side). The main gas-lighting circuit is cut at any point, and the two ends inserted in the binding posts.

This is absolutely all that is necessary to put it in use; no wires need be specially run, and no extra battery used.

The switch controls the battery entirely. When the lever is turned to "ON" the battery is then in circuit with the apparatus.

The bell itself is normally out of the circuit, and any or all burners may be operated as frequently as required, without the bell sounding at all. If, however, the battery becomes short-circuited or grounded, at the burner or elsewhere, for more than a given period of time for which the instrument is set by means of the adjusting-screw, then the bell is thrown into the circuit and sounds continuously while the trouble exists; but should it cease the bell is again out of circuit and the battery left in as before.



Another entirely new feature of this interesting instrument is that the bell is actuated by the main battery, and the current flowing through to the ground is diminished to so small an extent that the ground can be left on for hours without seriously affecting the battery.

Thus, while the current to a burner from the ordinary battery will be about one ampere, when the bell acts it will diminish immediately to less than three-tenths of an ampere.

The adjusting screw at the right side permits of the time adjustment. By slightly screwing it up, the time intervening between closing the circuit and the bell ringing will be shortened, and by unscrewing the reverse. They may be set to act at from any time between one-half a second and forty seconds. They are usually set for about five seconds when turned out from the factory of Mr. A. L. Bogart, the inventor.

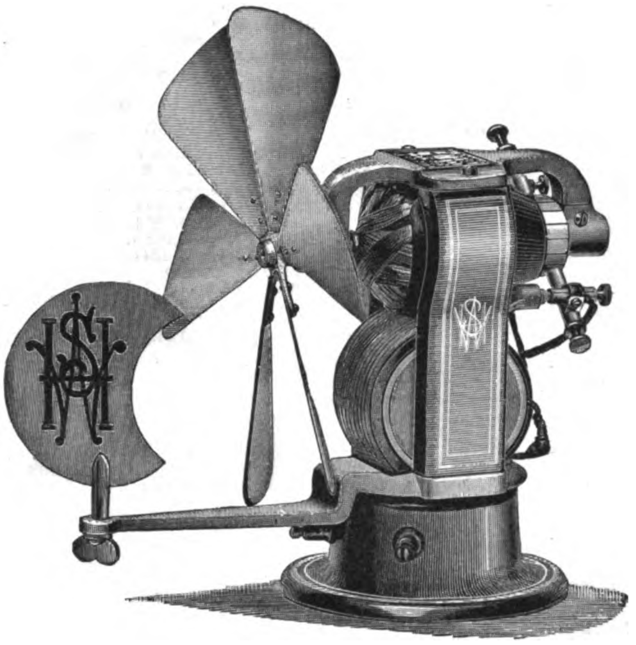
Whenever there is any one on the premises, this Automatic Short Circuit Alarm Bell will answer every purpose of a more expensive cut-off instrument, and can be attached to any gas-lighting circuit at any time by simply cutting the main wires and inserting them in the posts of this battery protector.

A Rotating Fan Motor.

The W. S. Hill Electric Company, Boston, is constantly introducing new specialties which instantly secure appreciation and sell right and left.

Their latest novelty is a rotating fan motor, of which we publish herewith a cut. It is similarly constructed to their well-known and efficient station fan motor in most details, but is mounted on a base which allows it to rotate by the action of the air from the fan. which impinges on a crescent shaped rudder, the rudder being adjustable at the end of a projecting arm to any angle, thus regulating the speed at which the entire machine shall rotate. This motor; when placed in the centre of a room, by its rotating motion will keep the air in motion in any part of said room, a feature the advantages of which are appreciable at a glance. This motor runs practically noiseless, keeps cool, is self lubricating, not requiring the use of a drop of oil for an entire season and without having to be touched.

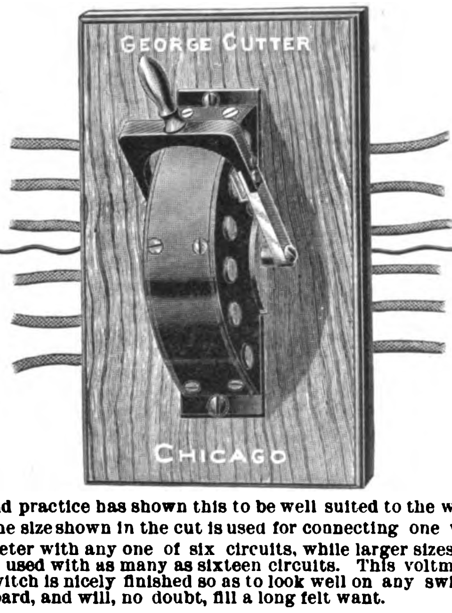
It has a twelve inch fan and makes 1,500 revolutions a minute on a 110 volt circuit, with less than one ampere of current. It is meeting with a phenomenal sale everywhere.



W. S. HILL ELECTRIC CO.'S FAN MOTOR.

Cutter's Voltmeter Switch.

The average incandescent station has quite a number of separate circuits running from it, and in order to maintain the proper voltage on each of these it has been the custom to have a voltmeter for each circuit. Then, since first-class instruments are rather expensive, the cheaper and more crude forms have almost always been used for this purpose. Of course, inaccurate voltmeters mean unsatisfactory service at the lamps, leading either to complaints regarding the light furnished or to a very short life of the lamps themselves. Any device that would allow a single and accurate voltmeter to be used with eight or ten circuits would do away with the faulty instrument and insure more satisfactory results. Mr. George Cutter, of Chicago, has perfected a special switch for this purpose, and practice has shown this to be well suited to the work. The size shown in the cut is used for connecting one voltmeter with any one of six circuits, while larger sizes can be used with as many as sixteen circuits. This voltmeter switch is nicely finished so as to look well on any switchboard, and will, no doubt, fill a long felt want.



The Ansonia Electric Company.

The Ansonia Electric Company have just closed a very large sale of Shield Brand Wire in Iowa.

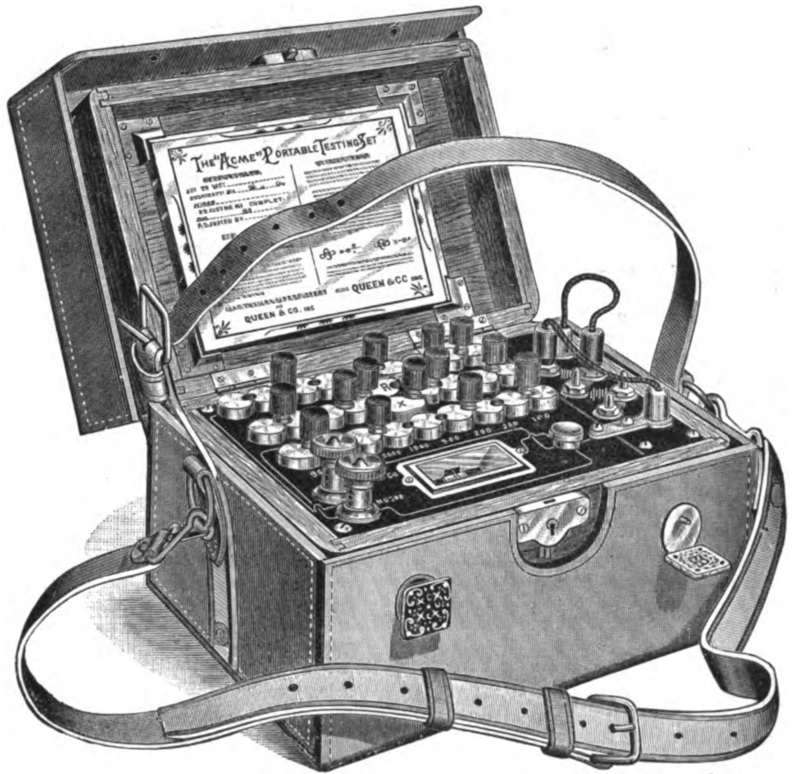
The many former buyers of the old Sunbeam lamps are taking advantage of the fact that the Ansonia Electric Company can again furnish the old standard Sunbeam incandescent lamp.

The Ansonia Electric Company advise that nothing but the best reports are coming in from the W.-W. Lightning Arrester.

The "Acme" Portable Testing Set.

The rapid and correct measurement of resistance under varying circumstances is an important factor in electrical engineering, and for this purpose it is highly essential to use apparatus that properly meets the requirements of everyday practical work.

In this connection the "Acme" Portable Testing Set, herewith illustrated and described, deserves more than passing notice as being one of the most perfect commercial instruments for testing resistance yet placed on the market, and embodying the result of long experience on the part of Queen & Company.



THE "ACME" PORTABLE TESTING SET
QUEEN & CO

ACME PORTABLE TESTING SET. (FIG. 1.)

It comprises a Wheatstone Bridge, Rheostat, D'Arsonval Galvanometer, "Aluminum-Iodine" Battery and Double Contact Key, all contained in a mahogany case, outside dimensions 8¼ inches x 5⅝ inches x 5 inches, and weighing less than six pounds complete. The leather case illustrated (Fig. 1) is very convenient when the apparatus is used by inspecting engineers, as it can be slung over the shoulder and carried as readily as a small handbag. The coils in both bridge and rheostat are wound with platinoid wire, which long use has conclusively shown to be far superior to German silver, and adjustments are made with great care, an accuracy of one-fifth of one per cent. being guaranteed. The arrangement is similar to the "Post Office" design, with three coils in each bridge arm, and eighteen coils in the rheostat, giving a total range, by means of the reversing attachment, of from .001 ohm to 11,110,000 ohms.

The galvanometer is a modified form of the D'Arsonval type, made specially for the purpose, and has proved a superior instrument for testing. It is strongly built, hence not liable to injury, and is perfectly dead-beat, so that readings can be taken very rapidly. Magnetic fields and mechanical vibrations produce no effect whatever, and the instrument will give as accurate indications in the street, on shipboard or in a dynamo room as in a college laboratory. This feature, possessed by no other make of similar apparatus, should not be overlooked.

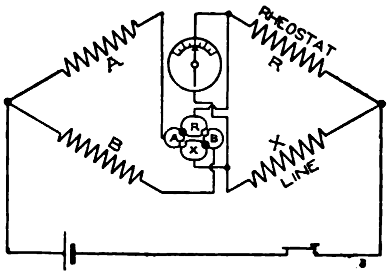
The battery is of the new "Aluminum-Iodine" form with E. M. F of 1 4-10 volts per cell, or equivalent to a total of 17 volts. This is practically 50 per cent. more than the ordinary chloride of silver cells.

The apparatus complete is shown in Fig. 1, while Figs. 2 and 3 indicate the arrangement of working parts. In Fig. 2 A and B represent the two proportional bridge arms, R is the adjustable rheostat, and X the unknown resistance or line. In Fig. 3 the arm A of Fig. 2 is equivalent to the coils 1, 10, 100 on the left hand centre row, and the arm B to the coils 10, 100, 1,000 on the right hand of same row. The rheostat R corresponds to the coils of the top and bottom rows, aggregating 11,110 ohms, and X the unknown quantity is connected between the two binding posts at the lower left hand corner.

In Fig. 3 the blocks marked "A," "R," "B," and "X" are connected to the bridge arms and are the same as shown in the centre of Fig. 2. They constitute the "reversing arrangement" whereby the bridge arms may be interchanged and six coils be made to do the work of eight. By this means it also becomes possible to readily detect inaccuracies in the bridge ratios should any exist, and to eliminate them entirely in work.

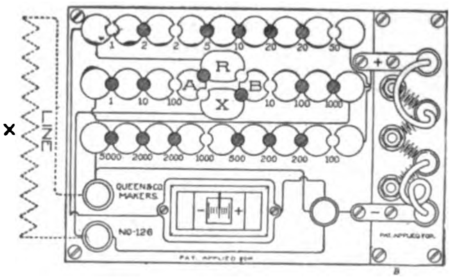
To use the apparatus the terminals of the resistance to be measured should be connected to the binding posts mentioned, and an approximate estimate formed of its value. For example, suppose it is about 400 ohms, the proper method of procedure will then be as follows;

Plug A to R and X to B, and unplug the 100 ohm coil in both A and B and also the 500 ohm coil in the rheostat. Connect one cell of battery and close the key for an instant (it is always best to start with very small battery power as in that case no harm can be done if the unknown resistance is estimated far from its proper value). If the galvanometer needle swings to plus, the resistance unplugged in the rheostat arm is too high; if to minus it is too low. By altering the unplugged resistance of the rheostat arm, and if necessary increasing the battery power, a "balance" can quickly be effected and thus the value of the unknown determined to within 1 ohm. Should the resistance be low, for instance, 10 ohms, the same plan should be followed except that the two 10 ohm coils of the bridge should be used instead of the 100 ohm coil. If the resistance be higher than the total resistance of the rheostat, for example 800,000 ohms, plug A to X and B to R and unplug 10 in A and 1,000 in B; the proportion will then be as 1 is to 100 and a balance will be obtained when 8,000 ohms is unplugged in the rheostat.



ACME PORTABLE TESTING SET. (FIG. 2.)

From the preceding description it will be evident that the apparatus is remarkably simple in operation, so that an inexperienced lineman can learn to use it in a short time. The great value of such an instrument will be evident to those who have used the forms heretofore obtainable, which usually necessitate the handling of two boxes, one for the rheostat, galvanometer and bridge, and a separate one for the battery.



ACME PORTABLE TESTING SEL. (FIG. 3.)

The manufacturers, Queen & Company, Incorporated, Philadelphia, will be pleased to quote prices and furnish further particulars upon application, as also to forward descriptive circular No. 445 to interested parties.

COMMERCIAL PARAGRAPHS.

The Eastern Electric Cable Company, Boston, manufacturers of the famous "Clark" wires and cables, notwithstanding that it has enlarged its factory two or three times the last two years, is still unable to keep up with the orders as they come rolling in. For the last two months they have had to decline any more orders, and though the factory is now running throughout both night and day, the company has business enough in hand to keep going for six months. This state of things has necessitated the erection of another new three story building, 151 feet long. The machinery will be run by a new Fitchburg engine of 150 H. P. Three 50 H. P. boilers will be installed. Clark wires and cables are known everywhere and need no recommendation, they recommend themselves every time.

The Muncie Electric Works, at Muncie, Ind., has orders on hand for a number of their "Iron Clad" machines, among which are two 25 h. p., three 10 h. p., one 15 h. p., three 1 h. p. and one 5 h. p.; they have delivered three 10 h. p. motors since beginning operations, May 1.

INCORPORATIONS.

The Voorhees Electric Company, Boston, Mass.—to manufacture and sell electrical appliances. Capital stock, $5,000. Stockholders: J M. Ladensack, Geo. R. Blinn. Gardner T. Voorhees.

The Essex County Street Railway Company, Newbury, Mass.—to construct a railway in Newbury, Rowley and Ipswich, and operate the same by any motive power except steam. Capital stock, $150,000. Stockholders; F. Cogswell, Chas. A. Sayward, Wm. S. Russell and others.

The Haverhill, Georgetown and Danvers Street Railway Company, Haverhill, Mass.—to construct a railway with switches in Danvers, Topsfield, Boxford, Georgetown and surrounding towns. Capital stock, $300,000. Stockholders: M. Brewster, Sherman Nelson, Jos. B. Poor, Merrill B, Bailey.

The Racket River Railway Company—to construct a standard gauge road about twenty miles in length, to be operated by steam or electric power, from Potsdam, N. Y., to and through the village of Pierpont to the village of Colton, with a branch at or near Hannawa Falls to Parrishville, in St. Lawrence County. Capital $350,000. Directors: W. Wyckham Smith, William Wills, Foster L. Backus, A. L. Chatterton and George R. Crossley, of Brooklyn; Russell L. Kinsay, of Buffalo; Frank E. Bennett, of Topeka, Kansas; J. L. Ludwig and A. R. Dodge, of New York City.

The Hoosic Railway Company—to construct an electric railroad from the Fitchburg Railroad Station in the village of Hoosic Falls, N. Y., through the village streets to Walloomsac. Capital, $60,000. Directors: G. C. Moses and F. H. Twitchell, of Bath, Me.; William Holmes, Joseph Buckley, S. D. Locke and others, of Hoosic Falls.

The Middletown-Goshen Traction Company—to construct a street surface railroad in Middletown, N. Y., about ten miles in length. Capital, $100,000. Directors: B. F. Low and A. D. Seaman, of Middletown; E. G. Wightman, S. W. Roberts, W. B. Rockwell, M. J. Wightman, F. W. Bleckley and B. H. Throop, of Scranton, Pa., and Samuel Harris, of Cleveland, Ohio.

The Lebanon Springs Railroad, which was sold at foreclosure sale in May, 1892, has been incorporated with the Secretary of State at Albany, N. Y., under the name of the Lebanon Springs Railroad, with a capital of $1,427,500.

The Litchfield Electric Light and Power Company of Litchfield, Conn., has been incorporated.

The East End Telephone Company—to construct and maintain a telephone line from East Hampton village to Sag Harbor and neighboring villages in Suffolk County, N. Y. Capital stock, $500. Directors: David J. Gardiner, Jerry Huntting, Edward M. Osborn, of East Hampton, and others.

New Hampton Electric Light and Power Company, New Hampton, Iowa. The company have obtained a franchise for the construction of an electric light plant at New Hampton to cost from $12,000 to $15,000. They also intend to construct and operate plants in other towns.

The Dubuque Light and Traction Company has filed its new articles of incorporation. The new articles provide for the purchase of electric light and electric street railway plants. The capital stock shall be $600,000, divided into 6,000 shares of $100 each. The annual meeting shall be held on the first Tuesday of June each year. Until the first annual meeting James S. Cummins, Walter J. Ballard, Edgar W. Duncan, George K. Wheeler and John L. Martin shall constitute the board of directors. The highest amount of indebtedness to which the company shall subject itself shall not exceed $400,000.

The Citizens' Electric Light Company, of Wayne, Pa. Capital stock, $5,000. Directors: John W. Yeatts, Frank Weckerley, Thomas H. Phillips, Louis Erben, St. Davids; Thomas H. Carter, J. H. Jefferies, Charles H. Barlit, Wayne.

The Mt. Pleasant Electric Light Company, Mt. Pleasant, Sanpete County, Utah. Capital stock, $10,000. President, L. J. Jordan; vice-president, Wm. Zabriske; secretary, W. D. Candland; treasurer, Alif Erickson. These and James Larsen form the board of directors. To furnish light and power.

At a recent meeting of the stockholders of the Schuylkill Traction Company, held at their office in Ashland, Pa., it was decided to increase the capital stock of the corporation from $600.000 to $10,000,000 and the mortgaged indebtedness from $300,000 to $500,000. The increased funds are to be used solely for the betterment and extension of the system.

At Albany, N. Y., on the 9th inst., the Colonial City Electric Railway Company was incorporated with a capital stock of $175,000 for constructing a street surface railroad six miles long in Kingston, N. Y. Directors: Charles W. Deyo, E. G. Lawrence, Elbert G. Loughran, Luke Noone, Alvah S. Newcomb and N. C. Powelson, of Kingston; Hasbrouck Alliger, of Rondout; Wendell Goodwin and Frederick Swift, of New York City.

The Chester Telephone Company, Chester, S. C. Capital stock, $500. Incorporators: A. W. Love, J. N. Cross, J. K. Henry, C. W. Carpenter. S. M. Jones. The purpose of the company is to operate telephone and telegraph wires in the town of Chester.

The Higgins Gravity Motor and Electric Gravity Clock Company, Chicago. Capital, $1,000,000. Incorporators: George C. Higgins, Samuel L. Smith and Joel J. Squier.

The Robertson Southern Electric Railway Company has filed an application for a charter to construct an electric railway from Knoxville, Tenn., to Kingston, Oliver Springs, Poplar Creek Coal Mines, Clinton, Andersonville, Powell's Valley, Luttrell, Maynardsville, Blaine's Cross Roads, Lee's Springs, Strawberry Plains, Dandridge, Sevierville, Allegheny Springs and the Little Tennessee River, in Monroe County, Tenn., with stems from the main lines to many points. The company expects to haul both passengers and freight, and in effect to eventually construct a cheap system of railways through all East Tennessee. The amount of capital stock is not set forth in the application. The incorporators are W. Boright, L. D. Dillon, B. H. Sprankle, J. S. McDonough, J.S. Stewart, J. Luttrell Murphy, Archibald J. Robertson, Henry Curry and J. A. R. Murphy.

Application has been made at Knoxville, Tenn., for a charter for the Paint Rock and Tennessee River Railway Company by J. W. Hudson, B. J. Miller, B. G. Slaughter, G. G. Phillips, Henry Estill and J. Luttrell Murphy, who propose to build an electric railway line from Winchester, Franklin County, Tenn., to McMinnville, by way of Decherd, Viola and Beersheba Springs The line is also to be extended to the head of Estill Fork Creek, of Paint Rock River, thence to Savannah, Mineral Springs, Lynchburg, Pulaski, Lawrenceburg and Waynesboro, in Wayne County.

The Ida Grove Electric Company, Ida Grove, Iowa. Capital stock, $15,000. Incorporators John L. Blakely, Wm. Bender, Alfred Shuter, F. A. Lusk, J. W. Reed, Wm. Bassett, H. M. Whinery, Julius Roher and Chas. Britch, all of Ida Grove. To establish and maintain an electric plant for power and light.

The Chester County Electric Railway Company has been granted a charter by the State Department at Harrisburg, Pa., to build a line of electric railway from Douglassville to Pottstown and Parker Ford. The corporators named are Eli S. Root, Jacob S. Mauger, William Smith, Samuel K. Halteman, David Titlow and William S. Mauger.

The Trenton Electrical Construction Company, Trenton, N. J. Capital stock, $25,000. Incorporators: George F. Applegate, Jeremiah P. Toman, Carl F. Adams, Anton Adams and Paul Suplee, all of Trenton. The object of the company is to manufacture operate and sell all kinds of electrical apparatus for lighting and for power purposes and for acquiring and dealing in patents and franchises.

The People's Street Railway Company, Chester, Pa. Capital stock, $50,000. Incorporators: Jas. R. T. Coates, Chester, Pa.; Samuel L. Kent, Clifton Heights, Pa; W. H. Sayen, Wayne, Pa. To construct and operate an electric railway in Chester, Delaware County, Pa.

The Shenandoah and Mahanoy City Street Railway Company, Ashland, Pa. Capital stock, $100,000, Incorporators: J. F. Bailey, Philadelphia, Pa.; D. D. Phillips, Gordon, Pa.; MacHenry Wilhelm, Ashland, Pa. To construct and operate an electric railway in Schuylkill County, Pa.

The Cleveland Surgical and Electrical Instrument Company, Cleveland, Ohio. Capital stock, $25,000. Incorporators: John R. McQuigg, Joel M. Monroe, Albert G. Langell, Geo. B. Riley, John Colahan. To manufacture and deal in surgical and electrical instruments, materials, etc.

The Hillsboro Water, Light and Power Company, Hillsboro, Texas. Capital stock, $50,000. Incorporators: D. M. Crossthwait, Kyle, Tex.; Walter Tips, Austin, Tex.; T. F. Voight, Dripping Springs, Tex. To supply the public with light and power by electricity.

The Hartman Manufacturing Company, New York, N. Y. Capital stock, $25,000. Incorporators; Edw. R. Vollmer, Brooklyn, N. Y.; Wm. Vollmer, Brooklyn; Julia Hartman, New York City. To manufacture and sell gas and electric fixtures.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JUNE 6, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

498,852. Closed Conduit for Electric Railways. Charles J. Kintner, New York, N. Y., assignor of one-third to Gustav Stahl, Philadelphia, Pa. Filed June 27, 1892.

498,906. Conduit Railway-Trolley. Michael H. Smith, Halifax, England. Filed April 6, 1886.

498,932. Trolley-Stand. James R. Griffiths, Chicago, Ill. Filed July 2, 1892.

498,933. Electric-Railway Trolley. James R. Griffiths, Chicago, Ill. Filed July 6, 1892.

498,985. Mechanism for Transmitting Power from Car-Wheel Axles to Dynamos Within the Cars. Morris Moskowitz and Samuel Young, Newark, N. J., assignors of one-half to Leon D. Adler and Joseph Loewenberg, same place. Filed Dec 6, 1892.

499,095. Trolley-Wire Finder. James Chase, Rochester, N. Y. Filed Jan. 23, 1893.

499,112. Overhead Electric Railway. John C. Henry, New York, N. Y. Filed Sept. 3, 1890.

499,115. Electric-Railway Trolley. George W. Hooper, Rochester N. Y., assignor, by direct and mesne assignments, of three-fourths to John A. Stewart, James S. Baker, and Alfred Green, same place. Filed Aug. 10, 1892.

499,143. Trolley-Wire Support. Carl Peterson, Brooklyn, N. Y. Filed Dec. 16, 1892.

499,167. Trolley-Wire Curve. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Feb. 2, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

498,878. Electric Illuminating Apparatus. Edward A. Colby, Newark, N. J. Filed Feb. 15, 1893.

498,879. Method of Electric Illumination. Edward A. Colby, Newark, N. J. Filed Feb. 15, 1893.

498,901. Incandescent Electric Lamp. Alexander De Lodyguine, Paris, France. Filed March 11, 1892.

498,915. Electrode for Electric-Arc Lamps. Saloman Heimann, New York, N. Y. Filed Oct. 24, 1892.

498,929. Electric Glow-Lamp. Edward A. Colby, Newark, N. J. Filed Feb. 15, 1893.

499,097. Electric Illuminating Apparatus. Edward A. Colby, Newark, N. J. Filed Feb 15, 1893.

499,150. Advertising or Other Illuminating Effect. Horace F. Simon, London, England. Filed Nov. 1, 1892.

DYNAMOS AND MOTORS.

498,763. Electro-Motive Device. Romaine Callender, Brantford, Canada, assignor of two-thirds to Edward Hart and Edward L. Goold, same place. Filed July 14, 1892.

498,969. Dynamo-Electric Machine. William S. F. Dillon, Chicago, Ill. Filed Nov. 21, 1892.

499,099. Electro-Dynamic Machine. Olof Dahl, Paterson, N. J., assignor to the Dahl Electric Company, of New Jersey. Original application filed Oct. 21, 1890. Divided and this application filed April 22, 1893.

499,183. Friction-Clutch for Electric Motors. Olof Dahl, Paterson, N. J., assignor to the Dahl-Electric Company of New Jersey. Filed Oct. 26, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

498,808. Telephone-Switchboard Annunciator. Frank R. McBerty, Downer's Grove, assignor to the Western Electric Company, Chicago, Ill. Filed Oct. 29, 1892.

498,869. Telephone Handle or Holder. Basil M. Wilkerson, New York. N. Y., assignor of one-half to Shipley Brashers, Washington, D. C. Filed April 14, 1891.

498,911. Copying Telegraphic Apparatus. Sylvester P. Denison, Belleville, N. J., assignor to Herman Broesel, trustee, New York, N. Y. Filed Feb. 1, 1893.

498,919. Telephone. Barton Pickering, Dayton, Ohio. Filed Oct. 4, 1880.

499,108. Telephone. Edward M. Harrison, Fort Smith, Ark. Filed May 31, 1892.

MEASURING INSTRUMENTS, ETC.

498,837. Dynamometer. Hans C. Behr, San Francisco, Cal. Filed Nov. 24, 1891. Renewed March 20, 1893.

498,871. Electrical Transmitter for Telemeter Systems. Charles W. Ayton, New York, N. Y. Filed Feb. 10, 1892.

498,872. Receiver for Telemeter Systems. Charles W. Ayton, New York, N. Y. Filed June 7, 1892.

SIGNALS AND SIGNALING APPARATUS.

498,864. Railway-Signal. James W. Steele, Chicago, Ill. Filed Oct. 5, 1891.

498,865. Railway-Signal. Joseph B. Stewart, Haverstraw, and William G. Wattson, Tappan, N. Y. Filed May 3, 1892.

498,987. Non-Interference Signal-Box. Charles E. Ongley, New York, N. Y., assignor, by direct and mesne assignments, to the Ongley Electric Company, same place. Filed Jan. 19, 1891. Renewed Nov. 16, 1892.

498,988. Electric Signal and Protective System. Charles E. Ongley, New York, N. Y., assignor, by direct and mesne assignments, to the Ongley Electric Company, same place. Filed Jan. 21, 1891. Renewed Nov. 16, 1892.

499,062. Electric Time-Signal. Gerhard W. Van Vlanen, Cologne, Germany. Filed Aug. 2, 1892.

499,125. Electric Signal Apparatus and System. Jacob W. Lattig, Easton, Pa. Filed April 12, 1893.

499,126. Electric Signaling Apparatus and System for Railways. Jacob W. Lattig, Easton, Pa. Filed Feb. 21, 1893.

MISCELLANEOUS.

498,757. Insulated Conductor. Thomas F. Attix, Brooklyn, N. Y., assignor of one-third to Henry C. Hulbert, same place. Filed Dec. 1, 1892.

498,768. Electrolytic Apparatus. Thomas Craney, Bay City, Mich. Filed March 25, 1892.

498,769. Method of Electrolyzing Salts. Thomas Craney, Bay City, Mich. Filed Aug. 10, 1892.

498,770. Electrolytic Apparatus. Thomas Craney, Bay City, Mich. Filed Aug. 18, 1892

498,771. Electrolytic Cell. Thomas Craney, Bay City, Mich. Filed Oct. 10, 1892.

498,776. Clamp for Electric Conductors. Axel H. Englund, Chicago, Ill. Filed June 29, 1891.

498,799. Rheostat. Edward R. Knowles, Middletown, Conn., assignor to the Schuyler Electric Company of Connecticut. Filed Jan. 9, 1893.

498,880. Electrical Switch. James Des Brisay, New York, N. Y. Filed Nov. 23, 1891.

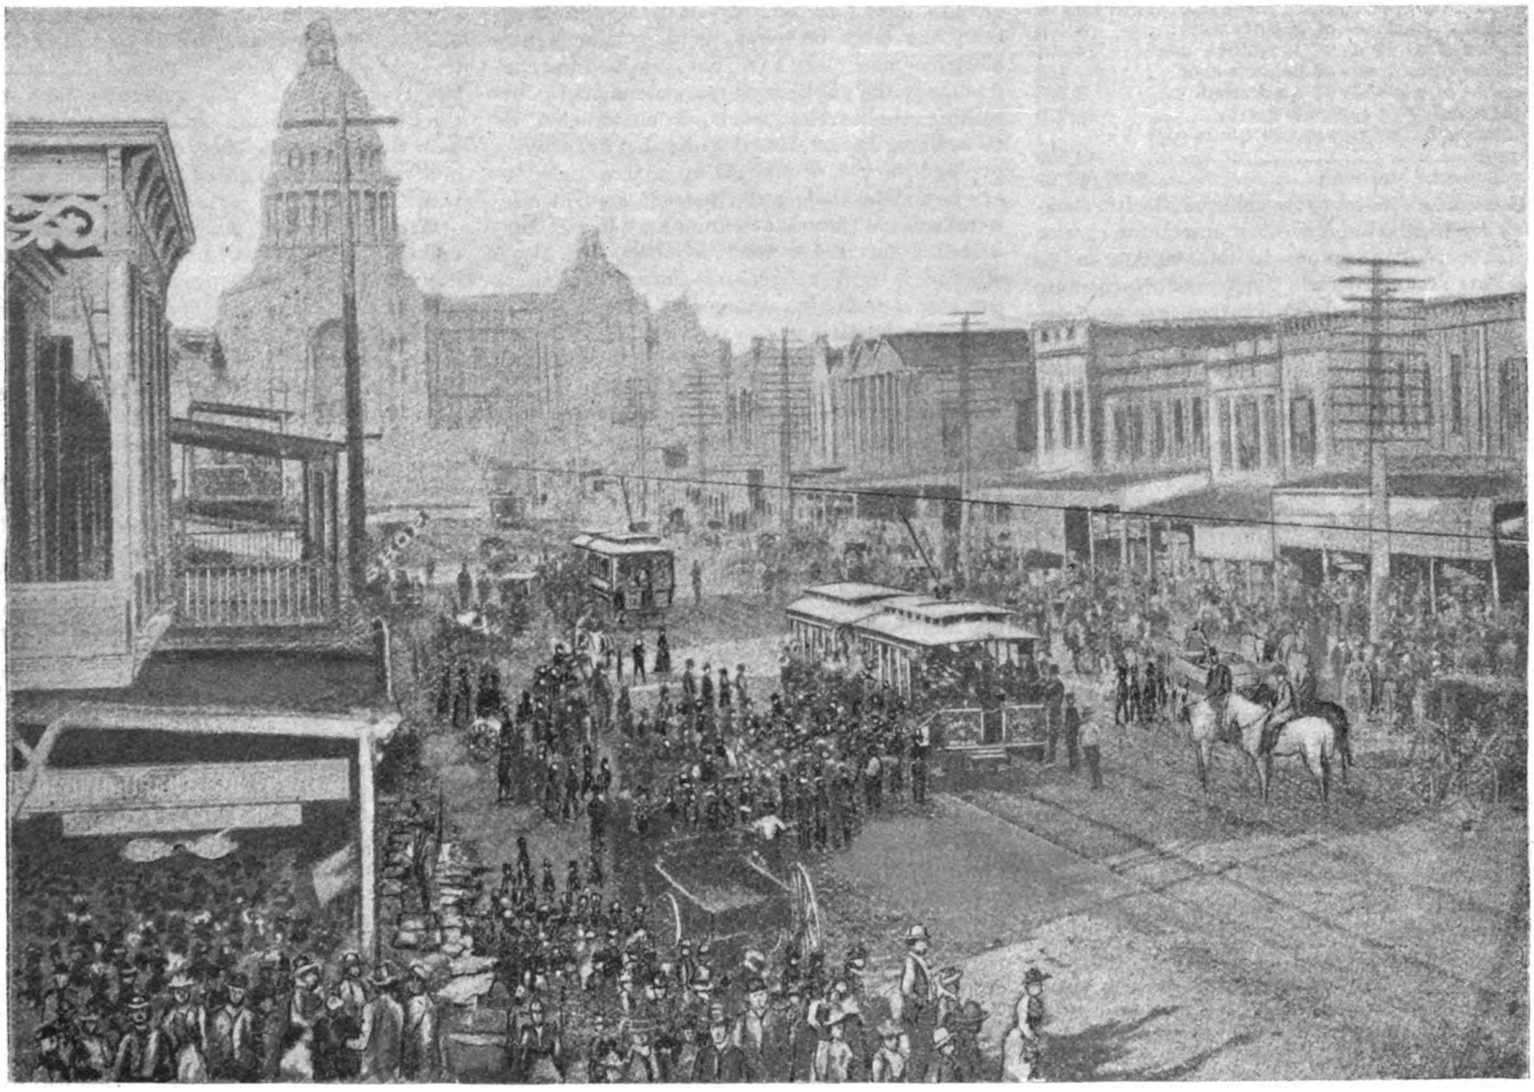
498,907. Electrical Condenser. William Stanly, Jr., and William B. Tobey, Pittsfield, Mass., assignors to the Stanley Laboratory Company, same place. Filed Jan. 9, 1893.

498,973. Method of and Apparatus for Electric Perforating. Dexter M. Garnett, Evanston, and John M. Garnett, Chicago, Ill. Filed Feb. 14, 1893.

499,008. Electrical Call-Box. Walter F. Banks, Milford, Conn. Filed Nov. 25, 1892.

ELECTRICITY.

VOL. IV. NEW YORK. JUNE 21, 1893. CHICAGO. No. 23



OPENING OF THE ELECTRIC RAILWAY, AUSTIN, TEXAS. (SEE PAGE 314.)

Austin's Water Power.

Electric Lights, Railway Power and Irrigation Supplied by the Colorado River Dam.

The city of Austin, Texas, has just completed a large dam which will utilize the power of the Colorado River for supplying the electric lighting of the city, drive its electric railways as well as furnishing water for irrigation of the farming lands in its vicinity and the city reservoir.

The suggestion of this project was made as early as 1888, since which it has been steadily agitated, but like most extensive works of this character there were many objections to overcome and considerable municipal legislation necessary before the project assumed definite shape. After making preliminary surveys and securing estimates on the work, it was found that the expense of the system as completed would amount to $1,400,000, for which amount city bonds were issued. The actual work was commenced in the latter part of 1890 and the system was put into operation on May 16, 1893. The dimensions and cost of the dam are as follows:

Length of dam, feet	1,150
Maximum height, feet	68
Height above low water, feet	60
Width at base, feet	66
Width at top, feet	16
Granite masonry in the dam, cubic yards	20,648.0
Limestone masonry in the dam, cubic yards	70,651.2
Concrete masonry in the dam, cubic yards	331.4
Total amount of masonry in the dam, cubic feet	91,630.6
Number of carloads of granite used	4,480
Number of carloads of limestone used	14,307
Number of carloads of cement used	456
Number of carloads of sand used	2,736
Total number of carloads used	21,979
Available horse power, 60 hours per week	14,500
Total cost of the dam	$607,927.90

Contracts were let to the General Electric Company for furnishing four 125 H. P. generators with switchboard connections to the stations, and to the Fort Wayne Electric Company for furnishing four 2,500 16 C. P. light alternating current incandescent dynamos, wound for 2,000 volts, and four 1,600 16 C. P. light alternating current incandescent dynamos, wound for 2,000 volts, making a total capacity of 16,400 lights, with all switchboard connections and necessary apparatus inside the station.

Our Frontispiece represents the scene at the opening of the electric railway line, the view being taken on Congress avenue, one of the main thoroughfares of Austin.

The work is of too recent completion to give any data as to its efficiency, but the operation of the system appears to warrant the most sanguine hopes of its projectors.

Electric Motors for Calico Printing.

Probably the manufacturers of Lancashire, Lanarkshire, and the other great centres of calico printing in this country, says the *Electrical Review* (London), will consider that their appliances have been developed sufficiently through years of experimenting into good practical machines, not easily to be improved upon; but they do not yet appear to have entertained to any great extent the possibility of driving their printing-machines by electric motors, although an admirable specimen of such a combination was to be seen in the Manchester Jubilee Exhibition of 1887 amongst the appliances shown by Messrs. Mather & Platt, of Salford Ironworks, Manchester. At the Dunnell Printing Works, of Pawtucket, Rhode Island, a complete arrangement has, however, been put into force, whereby the usual double-cylinder steam-engine employed to drive each machine is replaced by an electric motor, and so far with great success, the results being in advance of any other method used for actual daily work.

Electric Transmission of Power Over Long Distances.

Possibilities and Limitations Affecting its Successful and Economic Employment.

BY W. F. C. HASSON, MEM. TECH. SOC.*

During the past few weeks a number of technical and general papers on this subject have appeared in electrical journals. These articles, though full of interest to those connected with electrical pursuits, have not been of such a nature as to be of much assistance to the practical purchaser.

This latter has little interest in the methods by which the end is attained, the important points to him being the cost of installation, operation and maintenance of the machinery, the efficiency of the transmission, and the distance that it may be successfully accomplished.

Continuous current machinery has been brought to a high state of efficiency and regulation, and furnishes a perfectly satisfactory method of transmitting power to limited distances where low electromotive force can be economically employed. As the relations between electromotive force and strength of current and their connection with the *amount* of power generated becomes better understood, it appeared evident that unless high E. M. F. was employed the cost of copper would practically prohibit the transmission of power to long distances. The continuous current has strong advocates who do not hesitate to say that large amounts of power may be successfully commutated and distributed at an electromotive force of 5,000 or 6,000 volts. However, the large corporations that manufacture electrical machinery have not sustained the confidence of the public in these statements by furnishing commercial machines constructed on these lines. In fact, the company that has actively opposed the use of alternating current machinery now states that, in the present state of electrical science there is a definite limit to safe commutation far below that required, and if an attempt is made to generate heavy continuous currents at such high voltages the machines will inevitably break down.

So broad a statement concerning the final perfection of any electrical system may to-day be accepted with a fair amount of doubt. So firm is the belief of this particular company, however, that during the past year it has brought to a state of commercial perfection an alternating current system.

Notwithstanding the difficulties, certain able enthusiasts, notably Nikola Tesla, have devoted their entire time to the perfecting of commercial alternating current motor systems.

The transmission of power, for lighting purposes only, may be accomplished by means of any of the commercial alternating current systems.

The generators furnish an electromotive force sufficiently high to allow an economic distribution of power over several miles. By means of transformers, an electromotive force of 10,000 volts is easily obtained for transmission long distances to the point of distribution, where reducing transformers supply a safe pressure for local circuits. The success of this system is evidenced at San Antonio, Cal., where a transmission of 28 miles at 10,000 volts is now in operation.

The electrical manufacturing companies of America have been so engrossed in developing and exploiting their lighting and railway systems that they have apparently in the past given little serious attention to the perfection of systems to meet the needs of electric power on the Pacific Coast, and they have given still less consideration to the circumstances which render its employment possible.

During the past year, however, the question of long distance transmission has been extensively discussed, and the best energies of the electrical companies have been devoted to its satisfactory solution.

The result is that three alternating current systems in various stages of commercial perfection are now before the public. These are:

1. The single-phase or popularly called synchronous system.
2. The two-phase or diphase system.
3. The three-phase or triphase system.

The first of these systems has been commercially perfected to meet certain requirements. It is admirably adapted to the transmission of power that is to be used for the continuous operation of motors of not less than thirty horse power. Its success has been exemplified in the machinery that has now been in operation almost two years at Telluride, Colorado. Machinery for the transmission of power thirteen miles to operate the mills of the Standard Consolidated Mining Company is now being installed at Bodie, Cal.

The promoters of these two systems each claim great individual advantages, but, until they have been submitted to the test of commercial operation, the only claims that may be admitted are that the three-phase system requires less copper wire for transmission, and that the two-phase is somewhat more simple and better adapted to meet the possibility of a perfected single-phase motor.

Within three months a three-phase plant for the transmission of 300 horse power will be in operation at Redlands, Cal. Within less than a year one of these systems will be installed for the transmission of three thousand horse power twenty miles, under the guarantee that it will meet the requirements for all varieties of power, and that the efficiency of transmission from generator axle to point of distribution will be at least 79 per cent.

Whatever system is adopted, the cost of generators and motors will not vary greatly, and the important factor in a long distance transmission is the amount of copper necessary for the line.

In determining the feasibility of utilizing water power to operate electrically the industries of any particular town or city, careful consideration must be given of the following points, viz.:

1. The amount of water power permanently available.
2. The cost of developing this power.
3. The interest on this amount.
4. The total demand for power.
5. The amounts and relative locations of the various kinds of power.
6. The cost of steam plants now in operation.
7. The interest on this amount.
8. Cost of fuel for plants now in operation.
9. Cost of operating present plants. Labor.
10. Cost of maintenance of present plants.
11. The amounts and kinds of electric power already in operation.
12. The distance of transmission.
13. The estimated cost of the hydraulic machinery.
14. The guaranteed efficiency and regulation of the hydraulic machinery.
15. Estimated cost of electric machinery.
16. Estimated cost of line construction.
17. Total cost of operating hydraulic and electric machinery.
18. Total cost of maintenance of hydraulic and electric plants.
19. The interest on the total estimated cost of proposed plant.
20. The estimated gross income.

For further information on the many points to be considered in this connection I refer you to the articles by Messrs. C. L. Bradley and L. B. Stillwell, and Doctors Louis Bell and C. E.

---

* Abstract of paper read before the Technical Society of the Pacific Coast.

Emery, lately published in the electrical journals.

Undoubtedly, cheap power is essential to the development of the latent industries of California. It is equally true that the reliable electrical manufacturing companies are now prepared to furnish machinery to provide cheap power. The only difficulty in the way of advance appears to be a lack of confidence on the part of possible purchasers. This lack of confidence appears to be due to their inability to reconcile the conflicting claims and statements made by the electrical companies concerning their own machinery and that of competing companies.

Many transmissions that are easily possible are by no means feasible.

No long-distance transmission is absolutely impossible, although it may be thoroughly impracticable.

ON LIGHT AND OTHER HIGH FREQUENCY PHENOMENA.—IV.

BY NIKOLA TESLA.[*]

The streams of light which you have observed issuing from my hand are due to a potential of about 200,000 volts, alternating in rather irregular intervals something like a million times a second. A vibration of the same amplitude, but four times as fast, to maintain which over 3,000,000 volts would be required, would be more than sufficient to envelop my body in a complete sheet of flame. But this flame would not burn me up: quite the contrary, the probability is that I would not be injured in the least. Yet a hundredth part of that energy, otherwise directed, would be amply sufficient to kill a person.

The amount of energy which may thus be passed into the body of a person depends on the frequency and potential of the currents, and by making both of these very great a vast amount of energy may be passed into the body without causing any discomfort, except perhaps in the arm, which is traversed by a true conduction current. The reason why no pain in the body is felt, and no injurious effect noted, is that everywhere, if a current be imagined to flow through the body the direction of its flow would be at right angles to the surface; hence the body of the experimenter offers an enormous section to the current; and the density is very small, with the exception of the arm perhaps, where the density may be considerable. But if only a small fraction of that energy would be applied in such a way that a current would traverse the body in the same manner as a low frequency current, a shock would be received which might be fatal. A direct or low frequency alternating current is fatal, I think, principally because its distribution through the body is not uniform, as it must divide itself in minute streamlets of great density, whereby some organs are vitally injured. That such a process occurs I have not the least doubt, though no evidence might apparently exist, or be found upon examination. The surest to injure and destroy life is a continuous current, but the most painful is an alternating current of very low frequency. The expression of these views, which are the result of long continued experiment and observation, both with steady and varying currents, is elicited by the interest which is at present taken in this subject, and by the manifestly erroneous ideas which are daily propounded in journals on the subject.

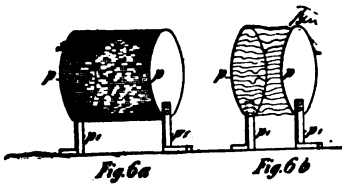


Fig. 6a Fig. 6b

Illustrating the Effects of Rapidly Varying and Steady Electrostatic Force.

I may illustrate an effect of the electrostatic force by another striking experiment, but must first call your attention to one or two facts. I have said before that when the medium between two oppositely electrified bodies is strained beyond a certain limit it gives way, and, stated in popular language, the opposite electric charges unite and neutralize each other. This breaking down of the medium occurs principally when the force acting between the bodies is steady, or varies at a moderate rate. Were the variation sufficiently rapid, such a destructive break would not occur no matter how great the force, for all the energy would be spent in radiation, convection and mechanical and chemical action. Thus the *spark* length, or greatest distance through which a *spark* will jump between the electrified bodies, is the smaller the greater the variation or time rate of change. But this rule may be taken to be true only in a general way when comparing rates which are widely different.

I will show you by an experiment the difference in the effect produced by a rapidly varying and a steady or moderately varying force. I have here two large circular brass plates *p p* (Fig. 6*a* and Fig. 6*b*), supported on movable insulating stands on the table, connected to the ends of the secondary of a similar coil as the one used before. I place the plates ten or twelve inches apart and set the coil to work. You see the whole space between the plate, nearly two cubic feet, filled with uniform light (Fig. 6*a*). This light is due to the streamers you have seen in the first experiment, which are now much more intense. I have already pointed out the importance of these streamers in commercial apparatus and their still greater importance in some purely scientific investigations. Often they are too weak to be visible, but they always exist, consuming energy and modifying the action of the apparatus. When intense, as they are at present, they produce ozone in great quantity, and also, as Professor Crookes has pointed out, nitrous acid. So quick is the chemical action that if a coil such as this one is worked for a very long time it will make the atmosphere of a small room unbearable, for the eyes and throat are attacked. But when moderately produced, the streamers refresh the atmosphere wonderfully, like a thunderstorm, and exercise unquestionably a beneficial effect.

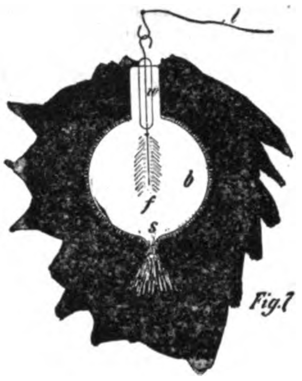

Fig. 7

Breaking a Bulb on Open Circuit.

In this experiment the force acting between the plates changes in intensity and direction at a very rapid rate. I will now make the rate of change per unit time much smaller. This I effect by rendering the discharges through the primary of the induction coil less frequent, and also by diminishing the rapidity of the vibration in the secondary. The former result is conveniently secured by lowering the E. M. F. over the air gap in the primary circuit, the latter by approaching the two brass plates to a distance of about three or four inches. When the coil is set to work you see no streamers or light between the plates, yet the medium between them is under a tremendous strain. I still further augment the strain by raising the E. M. F. in the primary circuit, and soon you see the air give way and the hall illuminated by a shower of brilliant and noisy sparks, 6*b*. These sparks could be produced also with unvarying force; they have been for many years a familiar phenomenon, though they were usually obtained from entirely different apparatus. In describing these two phenomena, so radically different in appearance, I have advisedly spoken of a "force" acting between the plates. It would be in accordance with accepted views to say that there was an "alternating E. M. F." acting between the plates. This term is quite proper and applicable in all cases where there is evidence of at least a possibility of an essential interdependence of the electric state of the plates, or electric action in their neighborhood. But if the plates were removed to an infinite distance, or if at a finite distance, there is no probability or necessity whatever for such dependence. I prefer to use the term "electrostatic force," and to say that such a force is acting around each plate or electrified insulated body in general. There is an inconvenience in using this expression as the term incidentally means a steady electric condition; but a proper nomenclature will eventually settle this difficulty.

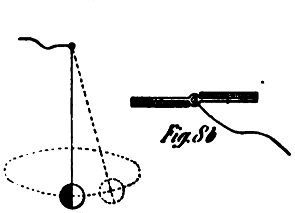

Fig. 8a Fig. 8b

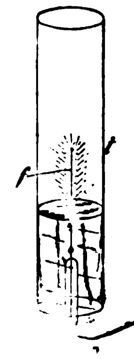
Mechanical Motions Produced by Varying Electrostatic Force in a Gaseous Medium.

I now return to the experiment to which I have already alluded, and with which I desire to illustrate a striking effect produced by a rapidly varying electrostatic force. I attach to the end of the wire *l* (Fig. 7) which is in connection with one of the terminals of the secondary of the induction coil an exhausted bulb *b*. This bulb contains a thin carbon filament *f*, which is fastened to a platinum wire *w* sealed in the glass and leading outside of the bulb, where it connects to the wire *l*. The bulb may be exhausted to any degree attainable with ordinary apparatus. Just a moment before, you have witnessed the breaking down of the air between the charged brass plates. You know that a plate of glass, or any other insulating material, would break down in like manner. Had I therefore a metallic coating attached to the outside of the bulb, or placed near the same, and were this coating connected to the other terminal of the coil, you would be prepared to see the glass give way if the strain were sufficiently increased. Even were the coating not connected to the other terminal, but to an insulated plate, still, if you have followed recent developments, you would naturally expect a rupture of the glass.



Showing the Effect of the Air.

But it will certainly surprise you to note that under the action of the varying electrostatic force the glass gives way when all other bodies are removed from the bulb. In fact, all the surrounding bodies we perceive might be removed to an infinite distance without affecting the result in the slightest. When the coil is set to work, the glass is invariably broken through at the seal, or other narrow channel, and the vacuum is quickly impaired. Such a damaging break would not occur with a steady force, even if the same were many times greater. The break is due to the agitation of the molecules of the gas within the bulb and outside of the same. This agitation, which is generally most violent in the narrow pointed channel near the seal, causes a heating and rupture of the glass. This rupture would, however, not occur, not even with a varying force, if the medium filling the inside of the bulb and that surrounding it were perfectly homogeneous. The break occurs much quicker if the top of the bulb is drawn out into a fine fibre. In bulbs used with these coils such narrow, pointed channels must therefore be avoided.

When a conducting body is immersed in air, or similar insulating medium, consisting of, or containing, small freely movable particles capable of being electrified, and when the electrification of the body is made to undergo a very rapid change—which is equivalent to saying that the electrostatic force acting around the body is varying in intensity—the small particles are attracted and repelled, and their violent impacts against the body may cause a mechanical motion of the latter. Phenomena of this kind are noteworthy inasmuch as they have not been observed before with apparatus such as has been commonly in use. If a very light conducting sphere be suspended on an exceedingly fine wire, and charged to a steady potential, however high, the sphere will remain at rest. Even if the potential would be rapidly varying, provided the small particles of matter, molecules or atoms, are evenly distributed, no motion of the sphere should result. But if one side of the conducting sphere is covered with a thick insulating layer, the impacts of the particles will cause the sphere to move about, generally in irregular curves, Fig. 8*a*. In like manner, as I have shown on a previous occasion, a fan of metal sheet, Fig. 8*b*, covered partially with insulating material as indicated, and placed upon the terminal of the coil so as to turn freely in it, is spun around.

---

[*] A lecture delivered before the Franklin Institute at Philadelphia, Feb. 24, 1893, and before the National Electric Light Association at St. Louis, Mo., March 1, 1893.

All these phenomena you have witnessed and others, which will be shown later, are due to the presence of a medium like air, and would not occur in a continuous medium. The action of the air may be illustrated still better by the following experiment. I take a glass tube *t*, Fig. 9, of about an inch in diameter, which has a platinum wire *w* sealed in the lower end, and to which is attached a thin lamp filament *f*. I connect the wire with the terminal of the coil and set the coil to work. The platinum wire is now electrified positively and negatively in rapid succession and the wire and air inside of the tube is rapidly heated by the impacts of the particles, which may be so violent as to render the filament incandescent. But if I pour oil in the tube, just as soon as the wire is covered with the oil all action apparently ceases and there is no marked evidence of heating. The reason of this is that the oil is a practically continuous medium. The displacements in such a continuous medium are, with these frequencies, to all appearance incomparably smaller than in air, hence the work performed in such a medium is insignificant. But oil would behave very differently with frequencies many times as great, for even though the displacements be small, if the frequency were much greater considerable work might be performed in the oil.

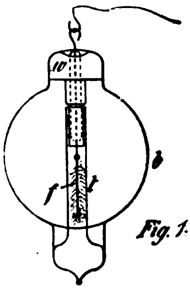


Fig. 10

Showing the Influence of the Conductivity of the Medium upon Electrostatic Actions through Measurable Distance.

The electrostatic attractions and repulsions between bodies of measurable dimensions are, of all the manifestations of this force, the first so-called *electrical* phenomena noted. But though they have been known to us for many centuries, the precise nature of the mechanism concerned in these actions is still unknown to us, and has not been ever quite satisfactorily explained. What kind of mechanism must that be? We cannot help wondering when we observe two magnets attracting and repelling each other with a force of hundreds of pounds with apparently nothing between them. We have in our commercial dynamos magnets capable of sustaining in mid-air tons of weight. But what are even these forces acting between magnets when compared with the tremendous attractions and repulsions produced by electrostatic force, to which there is apparently no limit as to intensity. In lightning discharges bodies are often charged to so high a potential that they are thrown away with inconceivable force and torn asunder or shattered into fragments. Still even such effects cannot compare with the attractions and repulsions which exist between charged molecules or atoms, and which are sufficient to project them with speeds of many kilometers a second so that under their violent impact bodies are rendered highly incandescent and are volatilized. It is of special interest for the thinker who inquires into the nature of these forces to note that whereas the actions between individual molecules or atoms occur seemingly under any condition, the attractions and repulsions of bodies of measurable dimensions imply a medium possessing insulating properties. So, if air, either by being rarefied or heated, is rendered more or less conducting, these actions between two electrified bodies practically cease, while the actions between the individual atoms continue to manifest themselves.

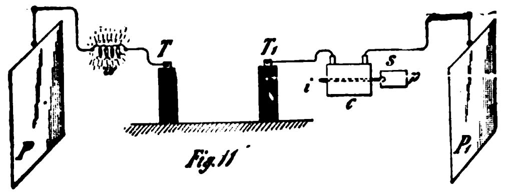

Fig. 11

Showing Effects of Currents flowing through Open Circuits.

An experiment may serve as an illustration and as a means of bringing out other features of interest. Some time ago I showed that a lamp filament or wire mounted in a bulb and connected to one of the terminals of a high tension secondary coil is set spinning, the top of the filament generally describing a circle. This vibration was very energetic when the air in the bulb was at ordinary pressure and became less energetic when the air in the bulb was strongly compressed. It ceased altogether when the air was exhausted so as to become comparatively good conducting. I found at that time that no vibration took place when the bulb was very highly exhausted. But I conjectured that the vibration which I ascribed to the electrostatic action between the walls of the bulb and the filament should take place also in a highly exhausted bulb. To test this under conditions which were more favorable, a bulb like the one in Fig. 10 was constructed. It comprised a globe *b* in the neck of which was sealed a platinum wire *w* carrying a thin lamp filament *f*. In the lower part of the globe a tube *t* was sealed so as to surround the filament. The exhaustion was carried as far as it was practicable with the apparatus employed.

This bulb verified my expectation, for the filament was set spinning when the current was turned on, and became incandescent. It also showed another interesting feature bearing upon the preceding remarks, namely, when the filament had been kept incandescent some time the narrow tube and the space inside were brought to an elevated temperature, and as the gas in the tube then became conducting, the electrostatic attraction between the glass and the filament became very weak or ceased and the filament came to rest. When it came to rest it would glow far more intensely. This was probably due to its assuming the position in the centre of the tube where the molecular bombardment was most intense, and also partly to the fact that the individual impacts were more violent and that no part of the supplied energy was converted into mechanical movement. Since, in accordance with accepted views, in this experiment the incandescence must be attributed to the impacts of the particles, molecules or atoms in the heated space, these particles must therefore, in order to explain such action, be assumed to behave as independent carriers of electric charges immersed in an insulating medium; yet there is no attractive force between the glass tube and the filament, because the space in the tube is, as a whole, conducting.

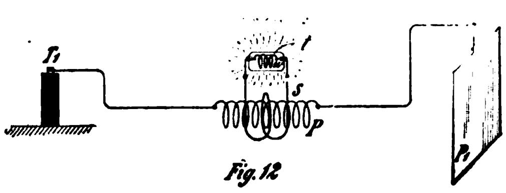

Fig. 12

Conversion on Open Circuit with Coil and Insulated Plate.

It is of some interest to observe in this connection that whereas the attraction between two electrified bodies may cease owing to the impairing of the insulating power of the medium in which they are immersed the repulsion between the bodies may still be observed. This may be explained in a plausible way. When the bodies are placed at some distance in a poorly conducting medium, such as slightly warmed or rarefied air, and are suddenly electrified, opposite electric charges being imparted to them, these charges equalize more or less by leakage through the air. But if the bodies are similarly electrified there is less opportunity afforded for such dissipation; hence the repulsion observed in such case is greater than the attraction. Repulsive actions in a gaseous medium are however, as Prof. Crookes has shown, enhanced by molecular bombardment.

ON CURRENT OR DYNAMIC ELECTRICITY PHENOMENA.

So far, I have considered principally effects produced by a varying electrostatic force in an insulating medium such as air. When such a force is acting upon a conducting body of measurable dimensions, it causes within the same, or on its surface, displacements of the electricity and gives rise to electric currents, and these produce another kind of phenomena, some of which I shall presently endeavor to illustrate. In presenting this second class of electrical effects, I will avail myself principally of such as are producible without any return circuit, hoping to interest you the more by presenting these phenomena in a more or less novel aspect.

It has been for a long time customary, owing to the limited experience with vibratory currents, to consider an electric current as something circulating in a closed conducting path. It was astonishing at first to realize that a current may flow through the conducting path even if the latter be interrupted, and it was still more surprising to learn that sometimes it may be even easier to make a current flow under such conditions than through a closed path. But that old idea is gradually disappearing, even among practical men, and will soon be entirely forgotten.

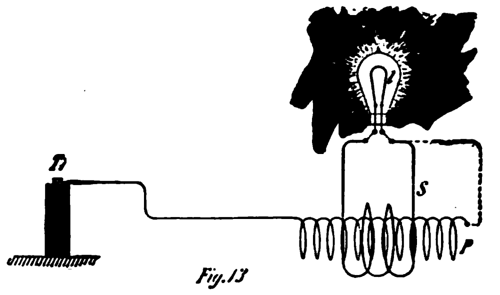

Fig. 13

Conversion on Open Circuit with Coil Alone.

If I connect an insulated metal plate P, Fig. 11, to one of the terminals T of the induction coil by means of a wire, though this plate be very well insulated, a current passes through the wire when the coil is set to work. First I wish to give you evidence that there *is* a current passing through the connecting wire. An obvious way of demonstrating this is to insert between the terminal of the coil and the insulated plate a very thin platinum or German silver wire *w* and bring the latter to incandescence or fusion by the current. This requires a rather large plate or else current impulses of very high potential and frequency. Another way is to take a coil C, Fig. 11, containing many turns of thin insulated wire and to insert the same in the path of the current to the plate. When I connect one of the ends of the coil to the wire leading to another insulated plate P, and its other end to the terminal T_1 of the induction coil, and set the latter to work, a current passes through the inserted coil C and the existence of the current may be made manifest in various ways. For instance, I insert an iron core *i* within the coil. The current being one of very high frequency, if it be of some strength, will soon bring the iron core to a noticeably higher temperature, as the hysteresis and current losses are great with such high frequencies. One might take a core of some size, laminated or not, it would matter little; but ordinary iron wire one-sixteenth or one-eighth of an inch thick is suitable for the purpose. While the induction coil is working a current traverses the inserted coil and only a few moments are sufficient to bring the iron wire *i* to an elevated

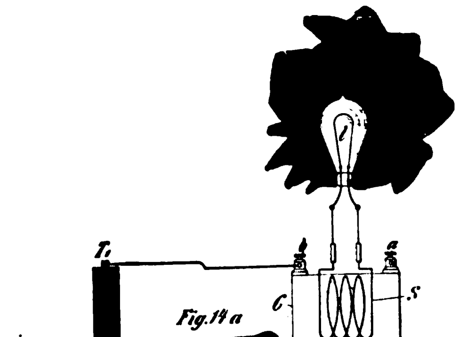

Fig. 14 a

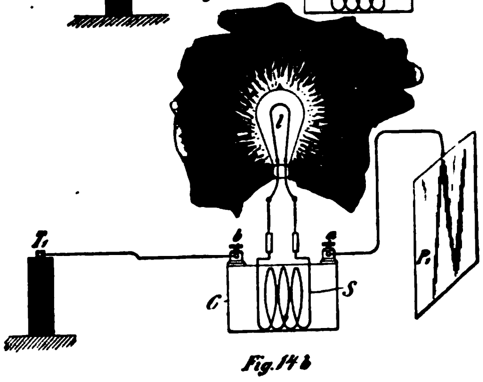

Fig. 14 b

Effect of Attached Plate with Low Frequencies.

temperature sufficient to soften the sealing wax *s* and cause a paper washer *p* fastened by it to the iron wire to fall off. But with the apparatus such as I have here, other much more interesting demonstrations of this kind can be made. I have a secondary S, Fig. 12, of coarse wire, wound upon a coil similar to the first. In the preceding experiment the current through the coil C, Fig. 11, was very small, but there being many turns a strong heating effect was nevertheless produced in the iron wire. Had I passed that current through a conductor in order to show the heating of the latter, the current might have been too small to produce the effect desired. But with this coil provided with a secondary winding, I can now transform the feeble current of high tension which passes through the primary P into a strong secondary current of low tension, and this current will quite certainly do what I expect. In a small glass tube (*t*, Fig. 12,) I have enclosed a coiled platinum wire *w*, this merely in order to protect the wire. On each end of the glass tube is sealed a terminal of stout wire to which one of the ends of the platinum wire *w* is connected. I join the terminals of the secondary coil to these terminals and insert the primary *p* between the insulated plate P_1 and the terminal T_1 of the induction coil as before. The latter being set to work, instantly the platinum wire *w* is rendered incandescent and can be fused even if it be very thick.

Instead of the platinum wire I now take an ordinary 50-volt 16 C. P. lamp. When I set the

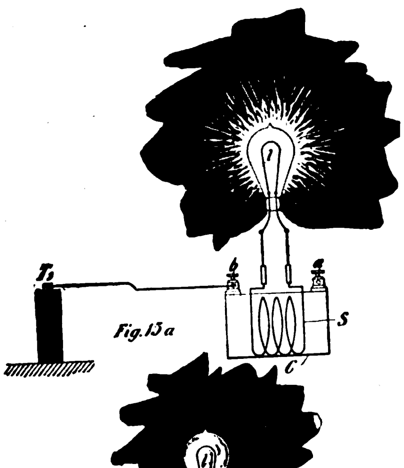

Fig. 15 a

Fig. 15 b

Effect of Attached Plate with High Frequencies.

induction coil in operation the lamp filament is brought to high incandescence. It is, however, not necessary to use the insulated plate, for the lamp (*l*, Fig. 13,) is rendered incandescent even if the plate P_1 be disconnected. The secondary may also be connected to the primary as indicated by the dotted line in Fig. 13, to do away more or less with the electrostatic induction or to modify the action otherwise.

I may here call attention to a number of interesting observations with the lamp. First, I disconnect one of the terminals of the lamp from the secondary S. When the induction coil plays, a glow is noted which fills the whole bulb. This glow is due to electrostatic induction. It increases when the bulb is grasped with the hand and the capacity of the experimenter's body thus added to the secondary circuit. The secondary, in effect, is equivalent to a metallic coating, which would be placed near the primary. If the secondary, or its equivalent, the coating, were placed symmetrically to the primary, the electrostatic induction would be nil under ordinary conditions, that is, when a primary return circuit is used, as both halves would neutralize each other. The secondary *is* in fact placed symmetrically to the primary, but the action of both halves of the latter when only one of its ends is connected to the induction coil is not exactly equal; hence electrostatic induction takes place, and hence the glow in the bulb. I can nearly equalize the action of both halves of the primary by connecting the other free end of the same to the insulated plate, as in the preceding experiment. When the plate is connected the glow disappears. With a smaller plate it would not entirely disappear and then it would contribute to the brightness of the filament when the secondary is closed by warming the air in the bulb.

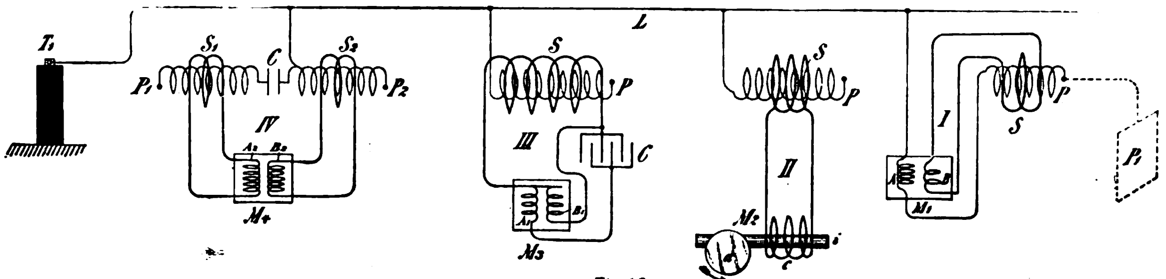

Fig. 16

Ways of Operating Motors with Only One Lead.

To demonstrate another interesting feature, I have adjusted the coils used in a certain way. I first connect both the terminals of the lamp to the secondary, one end of the primary being connected to the terminal T_1 of the induction coil and the other to the insulated plate P_1 as before. When the current is turned on, the lamp glows brightly, as shown in Fig. 14*b*, in which C is a fine wire coil and S a coarse wire secondary wound upon it. If the insulated plate P_1 is disconnected, leaving one of the ends *a* of the primary insulated, the filament becomes dark or generally it diminishes in brightness (Fig. 14*a*). Connecting again the plate P_1 and raising the frequency of the current I make the filament quite dark or barely red, Fig. 15*b*. Once more I will disconnect the plate. One will of course infer that, when the plate is disconnected the current through the primary will be weakened, that therefore the E. M. F. will fall in the secondary S, and that the brightness of the lamp will diminish. This might be the case, and the result can be secured by an easy adjustment of the coils, also by varying the frequency and potential of the currents. But it is perhaps of greater interest to note that the lamp increases in brightness when the plate is disconnected (Fig. 15*a*). In this case all the energy the primary receives is now sunk into it, like the charge of a battery in an ocean cable, but most of that energy is recovered through the secondary and used to light the lamp. The current traversing the primary is strongest at the end *b* which is connected to the terminal T_1 of the induction coil, and diminishes in strength towards the remote end *a*. But the dynamic inductive effect exerted upon the secondary S is now greater than before, when the suspended plate was connected to the primary. These results might have been produced by a number of causes. For instance, the plate P_1 being connected, the reaction from the coil C may be such as to diminish the potential at the terminal T_1 of the induction coil, and therefore weaken the current through the primary of the coil C. Or the disconnecting of the plate may diminish the capacity effect with relation to the primary of the latter coil to such an extent that the current through it is diminished, though the potential at the terminal T_1 of the induction coil may be the same or even higher. Or the result might have been produced by the change of phase of the primary and secondary currents and consequent reaction. But the chief determining factor is the relation of the self-induction and capacity of coil C and plate P_1 and the frequency of the currents. The greater brightness of the filament in Fig. 15*a* is, however, in part due to the heating of the rarefied gas in the lamp by electrostatic induction, which, as before remarked, is greater when the suspended plate is disconnected.

Still another feature of some interest I may here bring to your attention. When the insulated plate is disconnected and the secondary of the coil opened, by approaching a small object to the secondary, but very small sparks can be drawn from it, showing that the electrostatic induction is small in this case. But upon the secondary being closed upon itself or through the lamp, the filament glowing brightly, strong sparks are obtained from the secondary. The electrostatic induction is now much greater, because the closed secondary determines a greater flow of current through the primary and principally through that half of it which is connected to the induction coil. If now the bulb be grasped with the hand, the capacity of the secondary with reference to the primary is augmented by the experimenter's body and the luminosity of the filament is increased, the incandescence now being due partly to the flow of current through the filament and partly to the molecular bombardment of the rarefied gas in the bulb.

The preceding experiments will have prepared one for the next following results of interest, obtained in the course of these investigations. Since I can pass current through an insulated wire merely by connecting one of its ends to the source of electrical energy, since I can induce by it another current, magnetize an iron core, and in short perform all operations as though a return circuit were used, clearly I can also drive a motor by the aid of only one wire. On a former occasion I have described a simple form of motor comprising a single exciting coil, an iron core and disc. Fig. 16 illustrates a modified way of operating such an alternate current motor by currents induced in a transformer connected to one lead, and several other arrangements of circuits for operating a certain class of alternate motors founded on the action of currents of differing phase. In view of the present state of the art it is thought sufficient to describe these arrangements in a few words only. In the diagram, Fig. 16 II shows a primary coil P connected with one of its ends to the line L leading from a high tension transformer terminal T_1. In inductive relation to this primary P is a secondary S of coarse wire in the circuit of which is a coil C. The currents induced in the secondary energize the iron core *i*, which is preferably, but not necessarily, subdivided, and set the metal disc *d* in rotation. Such a motor M_2, as diagrammatically shown in Fig. 16 II, has been called a "magnetic lag motor," but this expression may be objected to by those who attribute the rotation of the disc to eddy currents circulating in minute paths when the core *i* is finally subdivided. In order to operate such a motor effectively on the plan indicated, the frequencies should not be too high, not more than four or five thousand, though the rotation is produced even with ten thousand per second, or more.

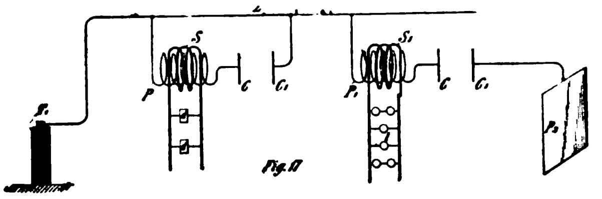

Fig. 17

Single Wire Conversion and Distribution, with Simple Means for Regulating the Effects.

In Fig. 16 I, a motor M_1, having two energizing circuits, A and B, is diagrammatically indicated. The circuit A is connected to the line L and in series with it is a primary P, which may have its free end joined to an insulated plate P_1 such connection being indicated by the dotted lines. The other motor circuit B is connected to the secondary S, which is in inductive relation to

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Hawks in the Eagle's Nest.

It would be very interesting to know just what has secured for a number of electrical fakes the privileges of space in the Electricity Building. That these privileges were willingly given by Mr. Hornsby is beyond belief, and yet there are exhibits, more than half a dozen in number, which would not be tolerated even in a respectable country fair.

Some months ago the official announcement went out that a close scrutiny would be made, and that no fakes would be admitted. Hence members of the fraternity generally, and exhibitors in particular, have rested in confidence; and now at the last moment, with the Fair well under way, the fakes omnipresent and presumably protected by permits, redress will be difficult if not impossible.

It would be unjust to characterize all the exhibits of electro-medical apparatus as fakes, as there are several reputable manufacturers represented whose displays must have a wholesome educational effect. But there are as many more of the other kind.

There is little doubt that this subject will be taken up in earnest by the entire electrical press. It is a service due to the public and to the art to make it as plain as possible just where the line should be drawn. That line must be far above "Actina," an "electrical" eye remedy, exhibited by the New York and London Electrical Association, which has a handsome booth at the very head of newspaper row. It is an unqualified fraud.

Directly opposite the booth of the *Electrical World* is a fake of a different nature. It is not medicinal, even in the claims of its boomers. In the opinion of the newspaper men who are compelled to endure its presence, its effect is directly the opposite of medicinal. In fact, it will lead to riot or a more serious offence if it is not speedily removed.

We refer to the abomination of abominations, the "electrical" hand-organ, which is even now, while this is being written, groaning out "Ta-ra-ra-boom-de-ay."

* * *

Water Powers.

The use of electricity is slowly but surely fulfilling the well-known predictions which have been made for it in the direction of power transmission from natural sources to the place of consumption, and this is especially true in the Western part of the country, where water power is often plentiful and the price of coal is invariably high.

Although there is great division of opinion as to the most efficient and practical system of current distribution, there are enough examples of long distance transmission from water powers now in operation to prove its value, and as the requirements which will secure greater efficiency can only be attained by a process of gradual evolution resulting from experience, it promises well for the future that the subject is receiving attention at present with the methods now at hand.

There is a tendency among users of electrical machinery to put off the introduction of a plant of this character until some new and superior method is introduced, and the rapidity of progress in electrical work is perhaps sufficient to account for this feeling, but the experience of the past ten years shows that waiting for the newest electrical device would mean to wait indefinitely as new schemes are proposed almost daily. In these applications of electricity the use of a high potential system is imperative on account of the cost of the lines, and whatever system is used must be capable of converting the current into power as well as light. The simple alternating current has solved the latter case, and current for lighting has been transmitted to considerable distances with good economy for several years.

The transmission of power, however, involves considerable more difficulty and is accomplished with a much lower efficiency. In many cases the single phase alternating current motor or the dynamo reversed will answer the requirements if the machines are not required to start under load, but as this condition is not always avoidable, other systems have been advanced to meet this objection. The use of direct constant potential currents with dynamotors for increasing the pressures at the station end of the line and reducing them at the point of consumption has been found feasible in some places, and the multiphase alternating systems, as well as the continuous direct current, have been introduced for the purpose of employing self-starting motors.

The question of efficiency is not of paramount importance where a sufficient water power exists. It is more often the first cost of construction that decides the question of electric transmission. The many places where water power abounds should be sufficient incentive for vigorous work in this direction, and now that it has been found feasible there will doubtless follow an era of electric power transmission in the same manner that electric lighting and railways were introduced as soon as they had been proved a success.

* * *

Through by Lightning.

The Chicago-St. Louis electric railway, which it was announced would be ready in time for the World's Fair traffic, on which a liberal portion of the road's receipts were based, has not for some time been prominently heard of, and as the contract for the electrical equipment of this road has only just been let it is not probable that many of the visitors to Chicago this summer will be able to enjoy the promised ride at a speed of one hundred miles an hour. From the description of this road and its financial status presented by Dr. Adams, about a year ago, before the New York Electric Club, the loss of patronage which the World's Fair was expected to furnish might be considered a somewhat severe blow to its prospects, as at that time it was estimated that $15,000,000 in fares would be received from visitors to the World's Fair, which would pay for the road two and a half times over. A single power station was at first supposed to be sufficient, but this was afterwards increased to two and recently to four stations, and the idea of utilizing water powers along the route has been abandoned. With a few more modifications in the plans, the road will be robbed of its novel characteristics and will bear a strong resemblance to the less pretentious electric railways now in common use.

Testing Coal by Electricity.

It is not, perhaps, too great a flight of imagination, says the *Electrical Review* (London), to assign this title to a method which W. Hempel has recently devised for use in determining the character of coal. Sulphur is a troublesome constituent which the gas companies would rather have absent from than present in their coals; moreover it seriously impairs the quality of the gas produced. The "monopolists" recognize *now* that they must strain every point in order to produce good gas; this has been forced upon them by competition, hence in this respect, too, electricity has done the public good service. W. Hempel is one of the leading authorities on coal-gas in Germany, and he has recently adapted a method, first devised in more complex form by Berthelot, whereby the sulphur in coals may be estimated, and hence their suitability for gas-making determined before purchase. In doing this he has taken advantage of the cosmopolitan aid which electricity offers. The coal to be tested is powdered and pressed into a little platinum wire cylinder, to which a long platinum wire is attached, and then burned. The combustion is effected in an ordinary glass bottle, which is fitted with a trebly perforated indiarubber stopper. Through this passes a tube with a glass stopcock, and which widens out into a cylinder; also two glass tubes, to the lower ends of which are fused two long thick platinum wires. One of these wires carries the little platinum cylinder or basket already referred to. A little mercury is poured into the tube so as to establish sure contact with wires which lead the electricity. When the current is passed the platinum basket becomes white hot, the combustion of the coal is effected, and the gaseous products containing the sulphur compounds are led off through the stopcock and examined chemically. This method is exceedingly neat, and gives, it is said, very satisfactory results, which enable the character of the coal to be accurately determined.

Lighting Statistics in Switzerland.

Statistics just published by Prof. Dezler of the Zurich Polytechnic School regarding the uses of electricity in Switzerland show that at the close of 1892 there were in operation 562 electric light installations, 53 plants for the transmission of power, 121 batteries of accumulators, and 1,056 dynamos and electromotors. The total capacity in kilowatts was 20,623, the number of incandescent lamps was 115,926 and of arc lamps 1,746. There were thirty-eight firms engaged in electrical works, seven of which were established last year.

Patent Office Exhibits at Chicago.

The Government Building contains a large number of models of early electrical inventions, among which is a model of a magnetic machine invented by Pixii in 1832, an engine by M. H. Jacobis in 1834, magnetic motor by Joseph Henry and an electric motor by Thos. Davenport in 1837. There are also more modern models of Gramme, Sims, Farmer, Fuller, Weston, Brush, Edison, Thomson, Houston and others. Besides these models of motors and dynamos there are others of arc lamps, meters, welding machines, converters, telephone and telegraph apparatus. There are also shown in this building samples of the apparatus used by the U. S. Signal Corps, both the stationary and portable sets.

The Societé Nationale des Sciences et des Arts Industriels, of Paris, are about to open an exhibition of all branches of trade in which electrical goods will form an important group.

(*Continued from Page* 317.)

the primary P. When the transformer terminal T_1 is alternately electrified, currents traverse the open line L and also circuit A and primary P. The currents through the latter induce secondary currents in the circuit S, which pass through the energizing coil B of the motor. The currents through the secondary S and those through the primary P differ in phase 90 degs., or nearly so, and are capable of rotating an armature placed in inductive relation to the circuits A and B.

In Fig. 16 III, a similar motor M_2 with two energizing circuits A_1 and B_1 is illustrated. A primary P connected with one of its ends to the line L has a secondary S, which is preferably wound for a tolerably high E. M. F., and to which the two energizing circuits of the motor are connected, one directly to the ends of the secondary and the other through a condenser C, by the action of which the currents traversing the circuit A_1 and B_1 are made to differ in phase.

In Fig. 16 IV still another arrangement is shown. In this case two primaries P_1 and P_2 are connected to the line L, one through a condenser C of small capacity, and the other directly. The primaries are provided with secondaries S_1 and S_2, which are in series with the energizing circuits A_2 and B_2 and a motor M_2, the condenser C again serving to produce the requisite difference in the phase of the currents traversing the motor circuits. As such phase motors with two or more circuits are now well known in the art, they have been here illustrated diagrammatically. No difficulty whatever is found in operating a motor in the manner indicated or in similar ways, and although such experiments up to this day present only scientific interest, they may at a period not far distant be carried out with practical objects in view.

It is thought useful to devote here a few remarks to the subject of operating devices of all kinds by means of only one leading wire. It is quite obvious that when high-frequency currents are made use of, ground connections are—at least when the E. M. F. of the currents is great—better than a return wire. Such ground connections are objectionable with steady or low frequency currents on account of destructive chemical actions of the former and disturbing influences exerted by both on the neighboring circuits; but with high frequencies these actions practically do not exist. Still, even ground connections become superfluous when the E. M. F. is very high, for soon a condition is reached when the current may be passed more economically through open than through closed conductors. Remote as might seem an industrial application of such single wire transmission of energy to one not experienced in such lines of experiment, it will not seem so to anyone who for some time has carried on investigations of such nature. Indeed I cannot see why such a plan should not be practicable. Nor should it be thought that for carrying out such a plan currents of very high frequency are implicitly required, for just as soon as potentials of say 30,000 volts are used the single wire transmission may be effected with low frequencies, and experiments have been made by me from which these inferences are made.

When the frequencies are very high it has been found in laboratory practice quite easy to regulate the effects in the manner shown in diagram Fig. 17. Here two primaries P and P are shown, each connected with one of its ends to the line L and with the other end to the condenser plates C and C^1, respectively. Near these are placed other condenser plates C_1 and $C^1{}_1$, the former being connected to the line L and the latter to an insulated larger plate P_2. On the primaries are wound secondaries S and S_1 of coarse wire, connected to the devices *m* and *d* respectively. By varying the distance of the condenser plates C and C^1, and C_1 and $C_1{}^1$, the currents through the secondaries S and S_1 are varied in intensity. The curious feature is the great sensitiveness, the slightest change in the distance of the plates producing considerable variations in the intensity or strength of the currents. The sensitiveness may be rendered extreme by making the frequency such that the primary itself without any plate attached to its free end satisfies, in conjunction with the closed secondary, the condition of resonance. In such condition an extremely small change in the capacity of the free terminal produces great variations. For instance, I have been able to adjust the conditions so that the mere approach of a person to the coil produces a considerable change in the brightness of the lamps attached to the secondary. Such observations and experiments possess of course at present chiefly scientific interest, but they may soon become of practical importance.

(*To be continued.*)

Gas Engine Sub-Stations.

We have more than once referred to the likelihood of gas engine sub-stations taking the place of electrical converter sub-stations where circumstances are favorable. The two essentials required are that coal should be abundant, and therefore cheap, and that the lighting should cover an area having compact districts, each of which could be supplied from a sub-generating station. The patchy character of such lighting is one which exists in several of our North country towns. In these, too, the gas monopoly is largely in the hands of the local authorities, which is an important point to consider when a municipal electricity supply is projected. The generating station would then be the gas works, and the high pressure feeders of a converted supply system would give place to gas mains. The Dowson gas plant would, in all probability, be that adopted, if existing works were not under municipal control; and, judging from the examples of this system which are at work, every confidence could be felt in the adoption of such a scheme. The Popp system in Paris would have possessed a much more valuable concession if gas had been taken as the medium for first distribution instead of compressed air. An additional argument in favor of gas engines used in this way has been afforded by the publication of figures as to the cost of lighting a large building by electricity from a private plant. It was there found, by exact experiment extending over two years, that with gas at 2s. 9d. per 1,000 cubic feet, the cost of gas worked out at 1·1 pence per unit generated, the total cost coming to 3d. per unit, including attendance, interest and depreciation of plant, etc. The resultant economy showed a saving of 12½ per cent. per annum in favor of electricity. It is rather a coincidence that Prof. Kennedy's estimate of the engine room cost per unit generated by the Westminster Company for this year should be the same figure, viz., 1·1 pence. We have recently devoted some attention to Liverpool electric lighting, and there the local circumstances have caused the company to go in for four generating stations rather than sub-station converters on a high tension system. The special knowledge of the managing engineer must have been the cause of their taking this course, and they express themselves as convinced of its wisdom. Here, again, is an argument in favor of gas engine sub-stations, for if economy is in favor of several stations rather than a single one of greater size, it seems not unlikely that when greater attention is paid to the gas engine in large sizes, and suitable means are taken to draw attention to the fact that such are to be obtained, some of the numerous supply concerns will find it to their interest to look very closely into the question, and to end by making a practical trial on a sufficiently large scale to prove that electricity can be so generated efficiently and commercially.

Mr. McMullen, who himself is advising a local authority, recently stated that one of the principal objections to gas engines was the varying crank effort. He assumes because a gas engine has a velocity which is susceptible of considerable variation throughout a complete stroke, therefore it must be unsuited to drive alternators. Were it necessary to run alternating machines parallel to obtain commercial success it would be another matter, but the engineer of one of our most successful stations has definitely and distinctly stated that from economic and financial considerations such a method of running is not essential. It may be, in some respects, advantageous and helpful, but need not stand in the way of alternator systems using gas engines as prime movers. If parallel running were so necessary the Metropolitan Company with their Willans alternator direct-coupled sets would be badly off, but the consensus of opinion is gradually, but surely, tending to a calmer and more impartial review of the *pros* and *cons* of what was once a burning question.—*Electrical Review*, London.

World's Fair Notes.

During the past week the electric fountains, located in the grand basin and about which so much has been written, were given their first public trial. The fountains, two in number, are situated on each side of the MacMonnies fountain and on account of their conspicuous position were supposed to be one of the leading evening attractions on the grounds. Owing to a lack of pressure on the water mains the jets of water did not ascend to the height expected and were therefore somewhat disappointing to the large crowd of visitors attracted to the grounds by the notice given out in the daily programmes. The principal trouble seems to arise from the fact that the water mains were not figured to stand the pressure required to force the water to the height specified by the fountain engineers.

In order to introduce an electrical feature into the French piano exhibit, located in the gallery of the Electricity Building, the manager of the exhibit has arranged a piano and a hand organ to run by electric motors. With this accession there is some pretense for having this exhibit located in the Electrical building.

Mr. Geo. Carter, manager of the Ansonia Electrical Company's exhibit at the Fair, reports among the many other sales made through their display a sale of a large variety of electrical heating apparatus.

The large Ferris wheel was given its first complete turn last week. The wheel consists virtually of two wheels mounted on a single axle. The thirty-six cars are supported about the circumference and travel around a circle 250 feet in diameter. The Ferris Wheel Company have installed a small electric light plant in their boiler room with which they intend to illuminate all of the cars and different portions of the wheel with incandescent lights.

A High-Speed Package Railway.

The transportation of mail matter and packages at a speed of 300 miles per hour is the object of a device invented by Albert L. Widdis, of Detroit, a model of which is now on exhibition at the World's Fair. It is an elevated railway with electricity as the motive power, and in appearance the car resembles a long, rectangular box, terminating at one end in a pyramidal projection running to a sharp point. This is the forward end of the car and is intended to reduce the resistance of the air. This car is suspended by iron hangers from four wheels 2 feet 6 inches in diameter, which in turn rest on a single bar of ordinary T-rail stretched on arms projecting from a line of poles. The patent cash carriers in use in many large shops closely resemble the method of suspension from a single rail employed by Mr. Widdis. Below this T-rail is an I beam which serves at once as a guide and a support and which prevents the wheels from leaving the main track. In the centre of the car is a specially designed electric motor of small weight and power that drives the car by means of sprocket wheels and link belts. The current to operate this motor is taken from a wire strung above the track by a trolley wheel much after the manner of the ordinary electric street car. The electric power is to be applied from generating stations at points along the route. Very little power is required. It is estimated that eleven horse-power will propel a 1,000 pound car with its load at the rate of 500 miles an hour.

The stopping of the car is done automatically in the following manner:

A lever projecting from the car comes in contact with a projection or arm from a post near a station which throws the lever backward and it catches in a corrugation. This cuts off the current, sets the brakes, and the car comes to a stop in front of the station. It may be well to explain here that there are both local and through cars. The lever or projection on the through car comes in contact with projections at central or terminal points only, while the lever on the local car comes in contact with the projection at every station, and the device in the local car is so arranged that it automatically throws open a switch, and the car runs in and stops in front of the station.

As the car passes along its route the bags or packages are automatically dropped at the proper place. This is accomplished by means of a lever coming in contact with a projection from a stanchion in front of the station. This lever works on a sprocket chain, on which there is a catch in the form of an acute angle, which as it passes around releases the bag which drops into a net. The storage compartments are bottomless to admit of this being done.

Patents on this system have been taken out by Mr. Widdis, and an experimental line near Detroit is to be constructed in order to put the system to a practical test.

Discharge through Gases.

A paper was read recently before the Royal Society by Prof. J. J. Thomson, F.R.S., on "Electrolysis of Steam," in which the repeated discharge of electricity through gaseous matter, noticed as ribbon flashes in lightning, is thus explained: "When an electric discharge passes through a gas, the properties of the gas in the neighborhood of the line of discharge are modified. Thus, as Hittorf and Schuster have shown, the gas in the neighborhood of the discharge is no longer an insulator, but can transmit a current under a very small potential difference. Faraday's remark, that when once a spark had passed through a gas the passage of another following immediately is very much facilitated, is another example of the same thing. We have thus good reasons for believing that when a spark passes through a gas it produces a supply of a modification of the gas, whose conductivity is enormously greater than that of the original gas. I have shown (*Phil. Mag.*, November, 1891,) that the conductivity of this modified gas is comparable with that of strong solutions of electrolytes. When the discharge stops, this modified gas goes back to its original condition. If now the discharges through the gas follow each other so rapidly that the modified gas produced by one discharge has not time to turn to its original condition before the next discharge passes, the successive discharges will pass through this modified gas. If, on the other hand, the gas has time to revert to its original condition before the next discharge passes, then the discharges pass through the unmodified gas. We regard this as being accomplished by means of successive decompositions and recombinations of its molecules, analogous to those which, on Grotthos's theory of electrolysis, occur when a current passes through an electrolyte."

Electricity to the Rescue.

During the whole of last week Barnum and Bailey's "Greatest Show on Earth" has been exhibiting in Boston along Huntington avenue. The crowds that have patronized the show have exceeded anything in past years, and how they were to be transported from the city to the show grounds was a problem the directors of the West End Railroad had to face and solve. To do this, the company actually put in special switches and turn-outs by means of which they were enabled to put on an extra service of electric cars. This prevented all possibility of interference with the regular traffic along the avenue, which is at all times heavy, so that the quarter million circus goers were accommodated in first-rate style, reflecting credit on the management of the road and demonstrating the value of electric propulsion.

Current Items.

A correspondent of the Philadelphia *Ledger*, writing of the exhibits in the Electricity Building, says: "I was disappointed in finding the business altogether in the hands of big corporations, with the inventors who developed and made possible the whole business so completely suppressed that even their names have almost disappeared. The building, however, remains for the general visitor one of the most interesting of the group."

At San Bernardino, Cal., representatives of the electric light company have been quietly at work on a project designed to supply the city of Los Angeles with electric power for lighting, railway and manufacturing purposes. "High up on the sides of Old Baldy, near the head waters of San Gabriel River," according to a press dispatch, "these men, after long-continued search, found an abandoned ditch and tunnel, used in early days for hydraulic mining, but abandoned over twenty years ago, which develops, according to careful estimates of engineers, 3,000 horse power in a fall of 700 feet. Work was begun last December in cleaning out the old ditch and repairing the tunnel, and is still going on. Lumber for the flumes has been packed on burros. A complete electric light plant has been secured, to be put into position when the other preliminary work has been done."

At the electric scenic theatre on the Midway Plaisance at the World's Fair, the performance is given in a fair-sized auditorium which during the display is dark. In front there is a miniature stage and through this opening the light effects upon the scenic production are given. The display consists of the Bay of Naples and Swiss scenery shown by sunlight and moonlight, the Alps during a thunderstorm and many other beautiful reproductions of scenery. The electric arrangement is such as to bring out the finest effects of the paintings.

Electricity promises to revolutionize the art of brickmaking by greatly reducing the amount of labor required. Instead of laboriously building a kiln, all that is necessary is to fit the clay into sets of iron molds with covers which contain 1,000 bricks each. The covers are fastened on, the current applied, and the work of burning is done in a very short time. The covers detach themselves automatically, and the bricks are ready to be tumbled on the stock for sale.

A new tree insulator has been introduced which greatly simplifies the problem of attaching wires to trees so that they may in no way come in contact with the branches. The insulator proper is on a shaft which works in a ball and socket joint, the cup of which is made fast to the tree. It matters not how much the tree may be swayed by the wind, for the line is kept by this means in its normal position, and is thus effectually prevented from coming in contact with any part of the tree and grounding the circuit.

Space for a fort on a hill near London is being cleared of tree stumps by an electric root grubber or stump puller. The dynamo for supplying the current is about two miles from the hill. The current is taken by overhead wires on telegraph poles to the motor on the grubber carriage. By means of belting and suitable gearing the motor drives a capstan upon which is coiled a few turns of wire rope. A heavy chain is attached to the tree roots, and as the motor is set to work and the rope exerts its force the roots come up quietly one after the other.

In certain iron lamp posts used abroad for arc lights a number of ornamental projections are thrown out by turning a key, enabling the trimmer to climb up without the aid of a ladder. The turning of the key also short-circuits the switch, making the lamp safe to handle.

The telephone has lately been arranged for use of divers. A sheet of copper is used in place of one of the glasses in the helmet, and to this a telephone is fixed so that the diver, when at the bottom of the sea, has only to slightly turn his head in order to report what he sees, or receive instructions from above.

Legal Notes.

The American Bell Telephone Company and E. Berliner have filed their answer to the bill lodged by the Government to annul the Berliner patent in the United States Circuit Court for the District of Massachusetts. The answer is a general denial of all the charges made in the Government complaint, and avers that due diligence was observed in the prosecution of the case in the Patent Office; that as a matter of fact the patent was ready for issue as early as 1882, and that the patent would then have been issued but for the action of Examiner Brown, who rejected all its claims, and raised other objections—all of which could have been done before that date. This action was appealed from to the board of examiners-in-chief, who, in February, 1889, reversed the decision of the examiner. It is also averred in response to the complaint that no new matter was introduced into the amended specification filed in 1880, after the acquisition of the patent by the Bell Company. The Bell Company also aver that in the application for the Berliner patent all due forms of law were observed, and that the Government cannot repudiate the acts of its own agents established by the laws creating the Patent Office.

Two suits for damages are now pending in the Circuit Court at Bay City, Mich., against the West Bay City Street Railway Company. The first is that of Mrs. Hannah Barrett for an accident which happened during a thunder storm. The lady took hold of the handles on the rear end of the car just as she stepped off, and received a shock which rendered her insensible. The company claim that they are not responsible for the accident, any more than they would be responsible for a shock of lightning which struck a person on their premises. The electricity did not come from the car, they aver, but from the air, and this will be their defense. The other case is that of a boy who was playing on the track and went to catch on a car. The car stopped, and he was standing behind it when the motorman reversed the current and the car backed up. The lad did not have time to get out of the way, and was dragged along by the dashboard, and so severely injured that he died. Administrators of the estate, which consisted mainly in the damage claim, were appointed, and as the boy was under age the suit is brought by them. The amount asked is $10,000.

Benjamin F. Peach, of Boston, Mass., has brought suit through Rose, Hemingway & Rose, in the Pulaski Chancery Court as a stockholder in the Little Rock, Ark., City Electric Street Railway Company to the amount of $20,000, to wind up the affairs of the corporation, and divide its assets equally among the creditors. This suit is brought under the recent act of the Arkansas Legislature, which enables any stockholder in an insolvent corporation to file a bill in chancery to wind up its affairs, the laborers and employees alone having the first lien on the property. The bill prays the appointment of a receiver and the enjoining of certain judgment creditors whose judgments were recovered within ninety days before the filing of the suit from executing such judgments.

The Gloversville *Intelligencer* states that the minority stockholders of the Johnstown and Gloversville horse car line will bring a suit enjoining the majority from leasing the road to the Cayadutta Company, on the ground that the lease was the result of sharp practice by stockholders of the latter company in securing a majority of the stock of the horse car line, electing what the minority stockholders call a "dummy" board of directors, and leasing the line to the Cayadutta Company at a figure just about large enough to pay the interest on the bonds, thus making the stock held by the minority stockholders practically valueless.

The temporary injunction preventing the Thomson-Houston Company from taking possession of the machinery at the power-house of the San Francisco and San Mateo Railroad Company, San Francisco, has been removed by Judge Garber; but while the Thomson-Houston Company has obtained legal sanction to take the machinery, Behrend Joost, president of the railroad, says it will not do so, as he and the company have arrived at a satisfactory solution of their differences, and that the electric company is willing to wait a little while for the money which is due.

Messrs. Babbit & Laurence, counsel for Louis Diebold, has applied to the Chancellor in Jersey City for a rule to show cause why a receiver for the American Engineering Company should not be appointed. The American Engineering Company was incorporated under the laws of New Jersey to build and equip electric railways. Diebold claims that the company has suspended all ordinary business, and has been insolvent for six months. The Chancellor reserved his decision.

The New Haven (Conn.) *Journal* says the case of the Edison Electric Company against the Perkins Electric Lamp Company and that of the Edison Electric Company against the Mather Electric Company, infringement of patents being the basis of both actions, which were to have been heard in the United States Court last week, by agreement of counsel were postponed subject to future assignment.

The Detroit Electrical Works plant was sold on the 12th inst. on a foreclosure suit for $100,000. W. H. Wells bid that amount for Hugh McMillan, and it was the only offer made. Mr. McMillan held mortgages to the amount of $200,000, and Judge Reilly ordered the sale because of default in the payment of certain promissory notes given to Mr. McMillan for money which he had advanced.

The application of the several steam railroad companies at Norristown, Pa., for injunctions to restrain the trolley companies from crossing their tracks at grade has been denied by the Court, who holds that a change of motive power to electricity cannot increase the danger at the crossings, and therefore refuses to interfere.

The Edison Phonograph Company of New York has filed in the United States Circuit Court several bills of complaint against Thomas H. McDonald, of Bridgeport, Conn. It is claimed that the defendant has infringed the complainant's patents for phonographs.

A company has been formed, with works at Providence, R. I., for the manufacture of the Field electric car fender, a new invention. The fender extends in front of the car 24 inches, and is formed of a series of steel wires that curve from the platform in a gentle swell to the bar in the front of the fender which is a few inches above the track. A rod with a ratchet attachment runs from the back of the fender to the inside of the dasher terminating with a padded end which is placed at just the height of the motorman's knee, so that, in case of any obstruction on the track, the motorman, by pressing with his knee on the pad, which he can do without moving out of his position, causes the front of the fender to drop to the track and a series of rollers prevents it from binding on the rough pavement. The steel wires are very elastic and a body striking the fender is scooped up on to the wires owing to their elasticity, the weight bending the wires so as to prevent its rolling off in front of the car.

Personal.

It gave us much pleasure to receive a visit of Saturday from Mr. Morgan Brooks, President of the Electrical Engineering and Supply Company of St. Paul, Minn., who has come East on business connected with his company. Mr. Brooks informs us that his company intends removing their plant from St. Paul to Minneapolis early in July. They have secured a site there and will erect capacious buildings to accommodate the different branches of their manufacture, one of these being the well known Packard incandescent lamp, a great trade in which the company has secured.

Mr. H. M. Haines, the railroad representative who has accompanied a great many of the special trains carrying the delegates of the National Electric Light Association to the various conventions, has just accepted the office of treasurer of the American Traveller and Tourist Company, a concern which conducts a general railroad, steamship and steamboat business at 849 Broadway, New York City.

Electricity and National Economy.

So much nonsense has been talked about electricity and its capabilities that we are glad to note the signs of a healthy revival of thought and an increasing desire to shake loose of the fetters of the imagination so often permitted to run riot when matters electric are mentioned. To romance is one thing, to talk drivel another, and it is a pity that avowedly respectable papers of the American technical press should lend themselves to strengthen what tutored minds regard as mere vaporings of an enthusiastic and ultra-sanguine mind.

Mr. E. Tremlett Carter, who is well known as having been one of the pillars of the now defunct Hanover Square School of Electrical Engineering, has a smartly written article in a recent number of a London electrical contemporary, under the above title, and we commend its perusal as a wholesome antidote to the cloying and nerve-shaking results which follow from an extended dose of the American view of electric possibilities. The average American writer, when freed from the recital of facts and the calming influence of the almighty dollar, "would, as it were, take us to the summit of Olympus, from which deific height we may survey all the kingdoms of the future of the world and the glory thereof. From such a lofty pinnacle it may be an unpleasant fall to the plain level earth, and to the facts and figures of political economy; but we must make it."

Certainly electricity is far from being a "cure-all" when applied to the boils and sores of our unhealthy modern body political. If we may judge of its probable influences in this country in years to come from what we see in the United States, it rather seems to be an all-important factor in intensifying and multiplying those evils of which some would have us believe it is the sovereign remedy. The remedy *may* prove worse than the disease, and the Yankees are already crying out bitterly enough to be saved from their reputed savior.—*Industries.*

An Electric Riding Whip.

The following description has been given of an electric whip for the use of riders. In the handle, which is made of celuloid, is placed a coil of fine wire with a small battery attached to it. The wire is over 2,000 yards in length. The circuit is closed by means of a spring and the ends of the wire are led to the end of the whip and terminate in two points sharpened so as to pierce the skin of the horse without wounding it. The whole weight of the whip is less than one pound.

Mr. Harness and the "British Medical Journal."

In November last the *British Medical Journal* published the following paragraph: "We have good grounds for stating that the *Times* has recently refused a four-column advertisement from the Harness Electropathic Belt Establishment, of the value of £80, a course worthy of the high and honorable traditions of that journal." "This paragraph," says the *British Medical Journal*, "was, in fact, inserted in the *Journal* with the sole object of raising boldly between ourselves and Mr. Harness the question whether the business carried on by him was a legitimate and honest one, or the very reverse; and we were prepared, at any cost and trouble, to have this question fully and fairly tried by a jury, and to abide by their decision on the issue presented to them. Accordingly, on the action being commenced, we admitted that we had published the paragraph complained of, and justified what we had written. Our readers will perhaps not be altogether surprised to learn that Mr. Harness, after we put in our defense to his action, took no further steps in the matter. Determined to bring him to book, after waiting a reasonable time, we applied for an order that Mr. Harness should be compelled either to go on or to discontinue this action, and an order was accordingly made that unless he proceeded to give notice of trial and to enter his action for trial within twenty-one days, it should be dismissed with costs. After what we have already stated, our readers will doubtless anticipate the sequel. The twenty-one days elapsed. Mr. Harness abandoned his action, and the same was dismissed with costs, since paid by him. These costs, being what are termed party-and-party costs, necessarily do not represent the expenses which the association has been put to in preparing to meet and justify the paragraph which Mr. Harness has allowed to go against him unrefuted. That, however, is a very small matter. The result of this abortive action is a convincing proof that Mr. Harness was not prepared to meet the charges brought against him by the *Journal* in open court, and is conclusive that all we have said on the subject of Mr. Harness and his so-called electric belts has been fully justified."

In some country towns the first running of electric cars causes as lively a commotion as the entry of a circus, and even the usually self-possessed editor of the local sheet is not unmoved by the occurrence, but is apt to spread himself in an elaborate report of the "trial trip," mingling descriptions of the scenery by the wayside, the vibrations and oscillations of the car and other incidentals of the trip with analytical notes of the sensations produced in the editorial *corpus* by "electrical propulsion." In a late number of a country paper, over a lengthy report, we find the following heading: "Trip over the Electric Road—Ovation at County Capital—Crowds of Men, Women, Children and Barking Dogs Greet the First Cars—A Delightful and Easy Trip Run Over a Well Constructed Road—Two Journeys Made, One in the Afternoon and the Other in the Evening." After which follows a full column of narrative, interspersed with complimentary references to the projectors and builders of the road, the conductor, the motorman, the car, the trolley and the track, with a truly rural account of the convivial proceedings that took place after the trolley was off.

Boston Notes.

The subject of placing electric wires underground in the city of Lynn is engrossing more and more public attention. A special committee of the city council to investigate the matter has been appointed and gone to work. As the New England Telephone and Telegraph Company owns and operates about eighty per cent. of all the overhead wires in the shoe city, that company has made a proposition to the city council that, if acted upon and certain very reasonable concessions be made, will result in nearly all wires going underground in a short time. The New England Telephone Company has placed nearly all its wires underground in Boston with very satisfactory results to themselves, their customers and the public generally.

An electric fountain is to be erected on the common in Lynn. After the exact design has been selected the fountain will be erected in the centre of the pond and it is intended to have it one of the most attractive pieces of work in New England.

About every business man in Boston is complaining that after a large expenditure of time and money by the special commission appointed for the purpose, the bill for securing rapid transit in and around Boston, that has just become law, is of such a visionary character as to make it seem improbable that anything will ever be attempted under it, hence the number of men who are formulating plans to be submitted to the State Legislature when that august body reassembles in the autumn. Meantime the crowded streets and congested traffic on the West End Railroad continue, and no one can predict within say ten years when any change will be attempted, to say nothing about its being consummated.

The Thomson European Electric Welding Company, whose offices are in Boston, on Thursday last re-elected the directors--Oliver Ames, S. Endicott Peabody, N. Smith, B. F. Spinney, Prentiss Cummings, G. P. Messervy, Henry D. Hyde and Francis Peabody, Jr. The sale of the European patents has not yet been effected, but the agent has still five months' option remaining, during which period it is hoped he may close a deal. The English company is in abeyance for the present. The stock in this enterprise has not been subscribed for nearly so freely as was anticipated, hence the comparatively slow progress the company has thus far made.

A somewhat amusing incident occurred in the State Militia camp at Framingham, Mass., a few days ago as the result of a mistake made by a signalman, who to save his legs essayed to transmit an order or command by flag signal rather than by telephone. By this mistake a whole troop of cavalry mounted their steeds and started off at a flying gait for brigade headquarters. It happened thus: A telephone message was received at the station near press headquarters asking for Lieut. Shaw, of Troop F. Now, Troop F was located a good half mile from the "phone," and the receiver, being anxious to save a walk, bethought himself of a brilliant scheme. The signal corps was working in front of headquarters and they undertook to transmit the message. In a minute the flags were waving and thrashing, and with some degree of pride the signal officer watched his subordinates doing their duty. When the message was ended, he exclaimed, "It is done; it's all right." Directly at the point where the message had been received there was a great commotion in the cavalry quarters; the bugle sounded the assembly, and with a rush and a dash the entire troop swept across the plain, nearly creating a panic in the ranks of the infantry, then in the field for drill. Drawing up his troops in front of brigade headquarters the captain of cavalry reported to the General in command as ready for duty. The General was as much astonished as anybody at the sudden appearance of the cavalry, but he had no duty for them to do and knew not why they had been called for. Explanations followed. It turned out that only the lieutenant of Troop F had been called for and not his men. The signal officer at once returned to his devotions while the cavalry rode back to their quarters, silently blessing (?) that signalman.

Mr. John Heinze, a talented young electrical inventor, who is at the head of the Heinze Electric Company, Lynn, has prepared a set of plans and drawings for an electrical fountain that is about to be erected on the common in that city. The plans are at present under consideration by a committee specially appointed by the City Council to select plans and carry out the work.

The Bell Telephone Company has just declared a dividend of 3 per cent. and an extra dividend of $3.00 per share as usual.

General News.

What is Going on in the Electrical World.

Saginaw, Mich.—A company has been organized here for the construction of a new telephone line.

Elmira, N. Y.—The new electric power station is nearly finished and is expected to be in running order July 1.

Waterford, N. Y.—The electors of this town have voted in favor of having electric lights. The Green Island Electric Works will furnish the light.

Berkeley, Cal.—The Berkeley Improvement Company, having gained possession of the electric light plant, will apply for the renewal of the lease.

Camden, N. J.--The Camden Horse Railroad Company has received permission from the board of public works to use electric motors on its tracks.

Martinsville, Ind.—The Martinsville Electric Light and Power Company have assigned to J. K. Scott. The liabilities amount to about $10,000, assets stated to be $17,000.

Humboldt, Tenn.—An electric lighting plant will be in operation here before the summer ends, the council having just closed a contract with a company to light the streets.

Youngstown, Ohio.—The route of the Youngstown and Canfield electric railway as decided upon runs past Lauterman's Falls to Cornersburg, thence via the Tippecanoe shaft to Canfield.

Shenandoah, Pa.—The Lake Side Electric Railway Company has been granted the right of way through this town in order to make connection with Lake Side Park, a local summer resort.

New York.—The board of directors of the Western Union Telegraph Company have declared a quarterly dividend of 1¼ per cent. for the three months ending June 30, payable at the office of the treasurer on and after July 15.

Pittsburg, Pa.—A travelling crane operated by electricity, to be erected in the ladle house of the converting mill of the Edgar Thomson Steel Works, was tested a few days ago and raised 100 tons. It will operate ladles exclusively.

Winchester, Tenn.—A St. Louis firm has the contract for building and equipping the Decherd branch of the Winchester system of electric railroads; also for putting in and equipping a large electric light plant for Winchester and Decherd.

Colorado Springs, Col.—The Colorado City Glass Company is making arrangements for putting in an electric light plant. The town board has agreed to contract with the company for the lighting of the city for a term of five years at $13 a month for each arc light.

Oneida, N. Y.—An electric road from Oneida to Silver Beach has many advocates, and a charter for that purpose will probably be applied for as soon as the plan is decided upon. Mr. Warner, the owner of the electric light plant here, is reported to be interested in the project.

Muncie, Ind.—A new electric railway scheme taking shape here is the building of a line twelve miles long from this city to Eaton, to be known as the Muncie and Eaton Electric Railway. George Reed and James Pixley are reported to be the leading promoters of the project.

Noblesville, Ind.—Dr. Gessner, the general manager of the Chicago and Central Indiana Electric Railway Company, is quoted as saying that the company has decided to extend its line from Lafayette to Chicago, thus making one of the finest systems of electric railway in the world.

Bellows Falls, Vt.—The construction of the electric road from this place to Saxton River, hindered on account of the death of one of the projectors, is likely to go on, as nearly all of the stock has been subscribed for. A number of good water powers will be made accessible by the line.

Brooklyn, N. Y.—The operating of the Fulton street cars by the trolley system has increased the amount of travel over that route fifty per cent. although it has been run less than a fortnight.—A trial of a new underground electrical system was made at Coney Island a few days ago. The patent is owned by the Universal Electric Company.

Frederick, Md.—A project under consideration here is the construction of an electric road from

Gettysburg, Pa., by way of Emmitsburg, Mechanicstown and Frederick to Washington. A road over this route, it is believed, would be largely patronized and could be made to pay handsomely.

Worcester, Mass.—The city council has authorized the making of a three year contract with the Worcester Electric Light Company for furnishing arc lights for the streets at the rate of 35 cents per light per night, a reduction of 5 cents from the price which has prevailed for the last three years.

Detroit, Mich.—The Standard Electric Company, which owns and manufactures the Logan storage battery, has lately been reorganized, and will carry on a more extensive business than hitherto. Its new officers are: President, R. E. Turner, of St. Joseph, Mo.; vice-president, W. T. Anderson, of St. Louis; secretary and treasurer, W. H. Little, of St. Louis.

Bayonne, N. J.—The Bayonne City Rapid Transit Company, a new corporation applying for a franchise to operate nine miles of electric railroad, will have a public hearing on the evening of June 26 at the City Hall. At the same time the old established Jersey City and Bergen Railroad Company will be heard with reference to its application to use electrical power.

Albany, N. Y.—As the time approaches for the electrical experiments on the Erie Canal interest in canal boat propulsion increases among the boatmen and others who are engaged in canal commerce. Superintendent Hannan states that he has received letters from about a dozen inventors who are convinced that they have motors that need only to be tested to show that they have solved the problem that is engaging so much attention.

Syracuse, N. Y—The men said to be most deeply interested in the projected electric railway between Syracuse and Manlius are Howell Smith, Miller A. Smith, Fred K. Fitch and E. W. Emmons, composing the New York Electrical Works, and William T. Corliss, of the Gillette Electric Works of Red Bank, N. J. The capital stock of the company is set at $250,000, and the name of the corporation will be the Syracuse, Fayetteville and Manlius Railway Company.

Minneapolis, Minn.—The Minneapolis *Tribune* says: "The Electrical Engineering and Supply Company of St. Paul, wholesale and retail dealers in and manufacturers of electrical machinery and supplies, have decided to change their base of operations from St. Paul to Minneapolis, and to materially increase their plant. The company expect to have the transfer of stock completed by July 1. In connection with their extensive wholesale business, the company will add a valuable addition to the manufacturing department for the purpose of manufacturing incandescent lamps."

St. Joseph, Mo.—The settlement of the affairs of the People's Street Railway is at hand, and the receiver is preparing to turn over the railway property to the St. Joseph Traction and Lighting Company, of which James T. Gardiner, of Albany, N. Y., is president. The new company will expend several thousands of dollars in improvements during the summer. The first step in this direction will be the purchase of new summer cars. These will be distributed on the various lines as needed. The next thing will be to replace the motors on all the cars now in use with new ones of an improved pattern.

New Haven, Conn.—The board of public works has granted permission to the Whitney Avenue line to use electricity as a motive power. —The *Journal* says: "The advent of the electric railway in the annex has given a great impetus to the prosperity of the east shore. All along its route new houses are springing up, especially on Woodward avenue, where a dozen new houses have been erected, all neat, comfortable-looking, attractive little homes. All the land on the avenue for a long distance has been sold in building lots, there never having been before in the history of the section any such call for land for building purposes."

Amsterdam, N. Y.—A new electric road to connect Amsterdam, Johnstown and Gloversville is under consideration. John H. McClement, president of the Amsterdam Street Railroad, and J. Seaver Page, a capitalist of New York City, having recently gone over the route, were very much impressed with the feasibility of building a road by which Gloversville can be reached from Amsterdam by a distance of only twelve miles. The present route over the Central and Fonda, Johnstown and Gloversville, is twenty-one miles. If the new line is built the distance will be reduced nine miles and the fare will be proportionally reduced.

Chicago.—The system of electric light buoys running from Chicago harbor to the Exposition grounds is nearly ready for operation. The work was done under the direction of Commander John J. Brice, U. S. N., inspector of the Ninth Light House District, and is said to be the greatest undertaking of the kind in the world. The system will consist of thirteen buoys, half a mile apart, each one surmounted by an incandescent light of great power, and visible eight miles in clear weather. In times of heavy weather and fog no difficulty will be experienced by pilots in picking out the next buoy when he has reached the first one, and each succeeding one in turn.

Hartford, Conn.—Open cars fitted with motors are to be put on the Glastonbury and East Hartford lines. The cars are expected to arrive daily. —The adoption of the storage battery system for running street cars in this city as against the trolley system has been under consideration in both branches of the common council for some time, but the question is still undecided. The councilmen, however, have requested the Wethersfield Horse Railroad Company to accept the proposition made to it by the Milford Company to equip three storage battery cars and run them on the Main street lines for six months as a test of the efficiency of the Milford system, the Hartford Company to receive 40 per cent. of all the receipts.

Newark, N. J.—The Consolidated Traction Company has secured control of the Newark Passenger Railway Company, a majority of the stockholders having agreed to sell their stock to the Consolidated Company (known as the Crimmins syndicate) on the basis of an exchange of the first mortgage 5 per cent. gold bonds of the Consolidated Company at par for railway company stock at $35 per share, with the express provision that the same terms of sale should be extended to all stockowners. The amount involved was $6,000,000. The Consolidated Company intends to spend $2,500,000 in building new lines in Newark streets, for which franchises have already been applied for, and in the improvement of existing lines.

A Mile in Thirty-two Seconds.

The question of relative speed of English and American railway trains has been, during the past two or three years, a standing theme of debate; the rival claims of the Scotch Express and the Flying Dutchman on the one hand, and the New York Central's famous Empire State Express on the other, each having staunch supporters, but now the New York Central comes to the front again with a record of 112½ miles an hour, which is surely the most marvellous performance of any railroad train past or present, demonstrating conclusively that this line possesses road-bed, rolling stock and motive power of the very best and highest type.

This remarkable run was made on May 11th by the new mammoth "Empire State Express" engine No. 999, hauling a heavily laden train, consisting of Wagner Palace Drawing-room and Combination Buffet, Smoking and Library Cars and two standard passenger coaches. Total weight, 241 American tons, or 482,000 pounds.

Commenting on this remarkable run the New York *Herald* says editorially: "The purpose of one line (the New York Central) to run a train to Chicago in 20 hours meets with no little objection from competing lines. The latter say the train won't pay; that it is not wanted, and they even intimate that it is not altogether safe. This opposition is obviously prompted by business considerations, though it seems to be a striking exception to the spirit of progress so often shown by American railway managers in promptly matching any improvement in speed or train service introduced by a competitor. In this matter public sympathy must be on the side of progress. With Americans time is money. They want the fastest trains attainable with safety, and are willing to pay for them. The same spirit which has prompted and demanded this advanced railway service has prompted and demanded progress in ocean travel. The crack steamers of to-day are floating palaces compared with those of years ago, while the time of the trip has been reduced season by season. As for railway travel, there is no reason why the progress of the future should not eclipse that of the past. Achievement has demonstrated that, so far as motive power is concerned, a speed of over 100 miles an hour is practicable. With safe rolling stock, safe road-bed and efficient management, security is assured."

The New York Central is a model road in every important particular. It has a magnificent road-bed, heavy steel rails, block signals, finest rolling stock procurable, and, to cap all, possesses four complete tracks throughout nearly its entire length. No. 999 and the Empire State Express will form a part of the New York Central's exhibit at the World's Fair.

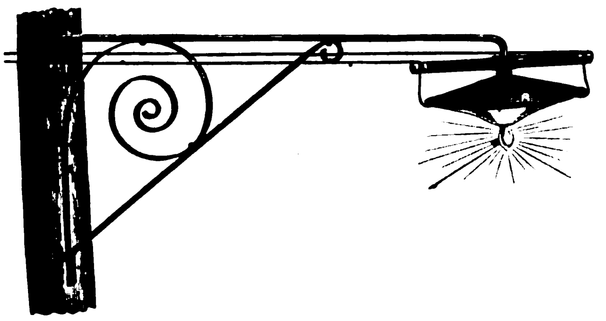
The New Stanley Transformer.

The complete and pronounced success attained by the new Stanley Transformer with its solid moisture proof insulation must be gratifying to its manufacturers, who aver that for regulation, efficiency, ease of handling, convenience of replacing primary fuses and ability to withstand lightning it has no competitor. The Ansonia Electric Company, Randolph street and Michigan avenue, Chicago, will promptly fill all orders for the new Transformer, and also for the new W.-W. Lightning Arrester, which is meeting with great success on account of its effectiveness, simplicity of construction and low cost. It will doubtless save many an armature.

Cutter's "Boulevard" Streethoods.

The streethoods designed and built by George Cutter are now in use throughout the country and so well known as to need no further comment. However there are cases where the goose-neck type of bracket arm is not ornamental enough to suit some tastes. This lack is met by the "Boulevard Streethood," illustrated herewith, which is aleady beautifying many streets in Western cities.

The various details of the hood and insulating arm are worked out the same as in the now standard form of hoods made by Mr. Cutter, the departure lying in the design of the supporting bracket, which is as strong and well braced as it is neat. The maker is exploiting them from his headquarters at the Rookery, Chicago.



CUTTER'S "BOULEVARD" STREETHOOD.

Ornamental Iron Work.

The Winslow Bros. Company, Carroll avenue and Fulton street, Chicago, have issued a trade-book for the current year to which the adjective superb might be appropriately applied, giving in the best style of art a large collection of photogravure plates, showing specimens of ornamental iron produced by the company. The number of plates in the collection is 141, of which 23 are of stairways and balconies, 17 of railings, 39 of elevator enclosures, 2 showing twelve designs of elevator cabs, 2 with eighteen designs of panels, medallions, etc., in Galvano-plastic, the remaining 68 being devoted to counter railings, entrances, canopies, grilles, lamps, frames, brackets, screens, skylights, etc.

The book is in every respect highly creditable to the company and all concerned in its preparation.

The Winslow Bros. Company have also published a lithograph edition, giving 88 plates, 11 x 14 inches, showing over 400 designs of ornamental iron work, and they intend issuing a monthly journal devoted to art metal work and embellished with numerous photogravures and half-tone illustrations.

The Page Belting Company has an extensive exhibit at the World's Fair, to the investigation of which they cordially invite all persons interested in belting.

A Flourishing Company.

The Interior Conduit and Insulation Company shows a constant and steady growth in its business which for the last three months has exceeded that of any similar period in its history. The interior conduit has now become the rule with all the first-class electrical installations, and there are but few large buildings of recent construction in New York City which are not equipped with this system of wiring.

The motors and electrical supplies manufactured by this company have also acquired a wide reputation among electrical men for their excellence of design and for the workmanship which is a characteristic of these goods.

The company has been obliged to constantly increase its manufacturing facilities from the start in order to meet the increase in its business, and results of the past three months have been ample justification of the large outlay of capital which its business has called for.

The General Incandescent Arc, Light Company's Catalogue.

Catalogue No. 1, just published by the General Incandescent Arc Light Company, 572-578 First Avenue, New York, is a handsome trade book, with a novel and attractive cover page containing a list of the lamps manufactured and dealt in by the company. The Catalogue is intended to supersede Circulars Nos. 1 and 2, which heretofore served to introduce the "General" Arc Lamps to the notice of electric light companies, contractors, architects, etc., and is of course much more comprehensive than the circulars. It contains illustrations and descriptions of the several kinds of lamps manufactured by the company, and of others added to their regular manufacture, together with brackets and other fixtures. Many of the examples given are beautiful in form and decoration and all of them are apparently well adapted for their various purposes. Prices are given with the descriptive notes.

Accompanying the catalogue are price lists of the high grade carbons of the company, who are sole agents for the United States and Canada of the Fabrik Elektrischer Belenchtungs Kohlen, of Nurnberg, Germany.

COMMERCIAL PARAGRAPHS.

Queen & Company, Incorporated, Philadelphia, report a large stock of "Magnetic Vane" Ammeters and Voltmeters which they can ship promptly and are pushing with great vigor. These instruments combine qualities highly essential for switchboard use, and which render them specially valuable for isolated plants.

A number have been supplied to exhibiting companies for installation at the World's Fair, and the makers have a handsome collection in their own display.

The "Acme" Portable Testing Set, described in detail last week, has met with favor wherever shown and is sure to become the standard instrument for general testing. Queen & Company have already received orders for more than twenty sets. Circulars 420 and 445, describing these specialties, can be had for the asking.

"The best mail yet," was an expression which dropped from the lips of Mr. Price, of the Pettingell-Andrews Company, Boston, a few mornings ago. This was a significant remark when it is known that this firm, the largest electric supply house in the East, is doing quite a phenomenal business—the increase in volume for the present year being over 40 per cent. better than last year.

A prompt and satisfactory piece of business was transacted by Mr. C. A. White, manager of the Eco Magneto Watchman's Clock Company, Boston, on Wednesday of this week. Just after 9 A. M., he received an enquiry by wire from Chicago as to price of two of their high-grade watchman's register. He replied by wire, which called forth an order for two—a 30 station and a 25 station equipment—before 12 noon, and within a couple of days the entire order was shipped West. These devices are being installed everywhere.

Mr. W. W. Jones, Eastern agent for W. R. Fleming & Company, makers of the Ide and Ideal Engines, is about completing installations as follows: A steam plant of 1,000 H. P. for the New Britain, Conn., Electric Street Railway Company, a 500 H. P. steam plant for the Taunto, Mass., Electric Light Company, a complete steam and electric lighting plant of 300 lamps at Martha's Vineyard, Mass. The "Ideal" engine was installed in each of these plants.

Though illustrated descriptions and advertisements in the electrical journals of a new revolving fan motor made by the W. S. Hill Electric Company, of Boston, appeared for the first time the last week, that company has had the pleasure of receiving enquiries in response for nearly 100 of these unique machines in three days. Who can say advertisements don't pay?

"Imitation is the sincerest form of flattery," says an old proverb which may be applied to Insullac, the excellent insulating material which the Massachusetts Chemical Company of Boston placed on the market a few months ago. So unprecedented has been the success "Insullac" has achieved that several imitations are being pushed, but not to the detriment of "Insullac," for the company after doubling its manufacturing capacity, working night and day forces, cannot keep up with the demand, and is at the present time shipping it in large quantities to Europe. "Once used, always used," is the universal verdict.

Mr. Brown, the live salesman of the Westinghouse Electric Company's Boston office, reports a continually increasing demand for railway equipment. During the past few days he has closed several good contracts and has several more under way.

The Ansonia Electric Company have recently gotten out a little circular describing the Wirt Dimming Switch, which switch is a great convenience and luxury in a bedroom or nursery for dimming the light. They also report an enormous sale in the last month of Habirshaw wire, and have just closed a contract for upwards of forty miles of Shield Brand Wire for lighting and power work.

INCORPORATIONS.

Articles of incorporation of the "C. & C." Electric Company were filed at Newark, N. J., on the 14th inst., by Joseph Wilkie, of Flushing, L. I.; G. D. Mumford, of New York, and Lloyd McKim Garrison, of Orange, N. J. Capital stock, $1,400 000: $400,000 preferred, $1,000,000 common. The object is to manufacture electric motors and appliances.

Citizens' Mutual Telephone Company, at Decatur, Ill. Capital stock, $100,000. Incorporators: W. J. Kurtz, R. Tobey, O. E. Harris, J. G. Harvey and O. T. Kirk.

City Illuminating Company, Chicago—to produce and furnish light for illuminating buildings, streets, etc., and to generate and distribute electrical currents for operation of motors, etc. Capital stock, $6,000. Incorporators: M. B. Austin, R. H. Watson and H. W. Ames.

The Novelty Electric Company, Chicago. Capital stock, $10,000. Incorporators: Howard M. Carter, Charles B. Carter and Edwin G. Lancaster.

The East St. Louis Electric Street Railroad Company has increased its capital stock to $500,000.

A charter has been granted at Harrisburg, Pa., to the Easton and Bangor Electric Railway Company, to build a road sixteen miles long. Capital stock, $100,000. Directors: Marshall Young, president; T. M. Lesher, J. P. Correll and D. W. Nevin, of Easton, and George Geaston of Mt. Pleasant, Pa.

The Niagara Electric Railway Company, with principal offices in Buffalo—to construct a street railroad between and in the villages of Pekin and Lewiston, Niagara County, N. Y. Capital, $50,000. Incorporators: Harvey Hoag, M. L. Failing, J. G. Charles, J. A. Kuck, of Buffalo, and others.

Rogue River Water, Light and Power Company, Grants Pass, Oregon—to construct, equip, maintain and operate water works and electric light system in the city of Grants Pass, Oregon. Capital stock, $50,000. Promoters: Geo. A. Pease, W. H. Pope, A. L. Pease, all of Portland, Oregon.

The Miamisburg Electric Company, Miamisburg, Ohio—to manufacture and deal in all kinds of electrical and other machinery and appliances, etc. Capital stock, $100,000. Promoters: T. V. Lyons, Wm. Gamble, Christian Weber, Elwood Allen, A. L. Daniels, Wm. A. Mays, Wm. Burnley.

The Portsmouth Street Railroad and Light Company, Portsmouth, Ohio—to operate street railroad and furnish light and power, etc. Capital stock, $125,000. Promoters: Samuel B. Timmonds, Jno. F. Brushart, George Davis, Anselm T. Holcomb, Floyd L. Smith.

Jackson Electric Railway, Light and Power Company, Jackson, Miss.—to carry on a general electric railway and power business in the city of Jackson. Capital stock, $250,000. Promoters: J. B. Harris, W. E. Hayne, J. B. Ross, all of Jackson, Miss.

The Continental Gas Company, Chicago, Ill.—to manufacture and deal in gas, electricity, erect, maintain and manufacture plants, appliances, etc., for operation of same. Capital stock, $10,000,000. Promoters: Chas. Springer, Ernest B. Stuart, Charles S. Corning.

Sloss-Stein Electric Company, Chicago, Ill.—to manufacture and sell electric appliances, metal products and specialties. Capital stock, $50,000. Promoters: Sydney Stein, Aaron M. Sloss, Louis Stein.

Tri-City Power and Light Company, Rock Island, Ill.—to manufacture appliances for and furnish light, heat and power to inhabitants of Moline and Rock Island and vicinity, gas, steam, air or electricity. Capital stock, $300,000. Promoters: R. H. MacMullan, Wm. Mullen, Jas. F. Hughes.

The Independent Electric Company, Chicago, Ill.—general electrical manufacturing and machine shop business. Capital stock, $25,000. Promoters: Wm. F. Hall, S. G. Hicks, N. D. Levin.

The Fairmount Railway Company, Denver, Col.—to build an electric railway from Fairmount Cemetery to Montclair in Arapahoe County. Capital stock, $10,000. Promoters: Willard Teller, Wm. H. Bush, Thos. H. Porter, Robt. H. McMann, Frank C. Young, all of Denver, Col.

The Riverside Electric Company, Riverside, Cal.—to generate electricity for all purposes and operate street railroads. Capital stock, $100,000. Promoters: Geo. L. Bush, Frederick Carter, Jno. T. Jarvis, B. B. Bush, Obed Patty, Riverside, Cal.

The Arizona Electric Company, Phœnix, Ariz.—to furnish light, heat and power and buy and sell all kinds of electrical machinery. Capital stock, $400,000. Incorporators: William Pickrell, W. F. White and Henry Kemp.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JUNE 13, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

499,270. Safety Support for Trolley Wires. Hiram K. Whitney, Chicago, Ill. Filed Feb. 6, 1893.

499,374. Conduit Electric Railway. William R. DeVoe, Shreveport, La. Filed Oct. 28, 1892.

499,461. Overhead Trolley Wire Switch. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Feb. 2, 1893.

499,633. Gearing for Electric Railway Cars. John C. Henry, New York, N. Y. Filed April 29, 1892.

499,662. Trolley-Wire Hanger. Charles B. Elliott, Boston, Mass., assignor to the Revere Rubber Company, same place. Filed Aug. 8, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

499,297. Electric Gas Lighting Apparatus. Thomas W. Lane, Boston, Mass., and Charles E. Lee, Chicago, Ill., assignors to the Electric Gas Lighting Company, Portland, Me. Filed Feb 8, 1892.

499,298. Electric Gas Lighting Apparatus. Thomas W. Lane, Boston, Mass., assignor to the Electric Gas Lighting Company, Portland, Me. Filed Feb. 15, 1892.

499,470. Shade Holder for Electric Lamps. Charles Remhof, Brooklyn, N. Y. Filed Feb. 13, 1891.

499,478. Electric Light. Gaston Sautter, Paris, France, assignor to Sautter, Harle & Company, same place. Filed Jan. 5, 1892.

499,676. Electric-Arc Lamp. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed March 28, 1893.

DYNAMOS, MOTORS, ETC.

499,350. Commutator for Dynamo-Electric Machines. Horace F. Parshall, Lynn, Mass., assignor to the General Electric Company of New York. Filed Jan. 13, 1893.

499,446. Alternating-Current Generator. William Stanly, Jr., and John F. Kelly, Pittsfield, Mass., assignors to the Stanley Laboratory Company, same place. Filed Jan. 9, 1893.

99,544. Regulator for Electric Machines. John C. Henry, Westfield, N. J. Filed Sept. 3, 1892.

MEASURING INSTRUMENTS.

499,318. Electrical Measuring Instrument. Edward Weston, Newark, N. J. Filed Oct. 3, 1892.

SIGNALS AND SIGNALING APPARATUS.

499 411. Electric Signaling Apparatus for Elevators. Charles G. Armstrong, Chicago, Ill., assignor of one-half to Dankmar Adler, same place. Filed Jan. 23, 1893.

MISCELLANEOUS.

499,253. Process of Magnetic Separation and Apparatus Therefor. Richard H. Sanders and Charles T. Thompson, Philadelphia, Pa. Filed Dec. 27, 1892.

499,254. Electric Hose Coupling. Howard Sargent, Cambridge, Mass. Filed Feb. 21, 1893.

499,261. Burglar-Alarm System. Alfred Stromberg, Chicago, Ill. Filed Feb. 11, 1893.

499,275. Safety Device for Systems of Distribution. Herbert C. Wirt, Boston, Mass. Filed March 16, 1892.

499 305. Electric Bell. John L. Moore, New York, N. Y. Filed June 6, 1892.

499 321. System of Propelling Canal-Boats by Electricity. Samuel W. Gear, Buffalo, assignor of one-half to John F. Alden, Rochester, N. Y. Filed Jan. 26, 1893

499.363. Electric Switch. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car-Heating Company, Wheeling, W. Va. Filed Nov 16, 1892.

499,425. Strong-Current Protector. Charles D. Haskins, Brooklyn, N. Y., assignor to the Western Electric Company, Chicago, Ill. Filed Sept. 9, 1890.

499,428. Electric Hinge. William S. Hull, Sheffield, Ala. Filed Nov. 16, 1892.

499,497. Cut-Out. Patrick J. Barrett, Boston, Mass., assignor of one-half to John J. Frawley as President of the Boston Society of Redemptorist Fathers, same place. Filed April 3 1893

499,518. Method of Electrically Welding Metals. Charles L. Coffin, Detroit, Mich. Filed Sept. 25, 1890.

499,543. Electro-Magnetic Car-Brake. John C. Henry, Westfield, N. J. Filed Aug. 8, 1892.

499,572. Apparatus for the Production and Inhalation of Ozone. Marie P. Oudin, Paris, France, assignor to Jules Ehlis, Liege, Belgium. Filed Dec. 10, 1891.

499,596. Electric Igniting Device. William H. Russell and George E. Russell, Jersey City, N. J. Filed Mar. 9, 1893.

499,610. Recorder. John T. Todd, Newman, assignor, by direct and mesne assignments, to the Todd Applegate Company, Chicago, Ill. Filed May 24, 1892.

499,614. Multiple-Fuse Block. Gardner T. Voorhees, Boston, assignor to James E. Maynadier, Taunton, Mass. Filed Sept. 1, 1892.

499,646. Switch. George W. Russell, Jr., Denver, Col. Filed April 7, 1893.

499,657. Method of and Apparatus for Electrically Welding Sheet Metal. Charles L. Coffin, Detroit, Mich. Filed Oct. 18, 1892.

499,664. Electric-Fuse Block. Thomas J. Fay, New York, N. Y., assignor to James L. Doolittle, Brunswick, Me. Filed Feb. 11, 1891. Renewed May 2, 1893.

499,681. Electro-Magnetic Blanket. Nils A. Renstrom, Omaha, Nebr., assignor of one-half to James S. Stone, same place. Filed April 15, 1893.

499,693. System of Wiring Multiple Switchboards. Charles H. Wilson, Chicago, Ill., assignor to the Western Electrical Company, of Illinois. Filed Oct. 8, 1888.

ELECTRICITY.

VOL. IV. NEW YORK. JUNE 28, 1893. CHICAGO. No. 24

THE FERRIS WHEEL AT THE WORLD'S FAIR. (SEE PAGE 326.)

The Ferris Wheel.

The Ferris Wheel, the crowning engineering feature of the Columbian Exposition, was thrown open to the public last Wednesday before a large audience of invited and distinguished guests. Over five thousand people were present to see the enormous body of iron make its formal turn for the public pleasure and comfort.

The wheel is certainly one of the most remarkable structures that have ever been designed or erected. As the Brooklyn Bridge and the Eiffel Tower have been as milestones to mark the progress made in engineering in the past, so will the Ferris Wheel be added to mark another advancing step. The Ferris Wheel is to the Columbian Exposition what the Crystal Palace Hall was to the Crystal Palace Exposition, or the Eiffel Tower was to the Paris Exposition. Although the electrical features of the wheel are of a secondary nature, the wheel itself is deemed of sufficient importance to warrant a short description in these columns.

The highest point is 265 feet above the surface of the earth. The diameter is 250 feet and the circumference 825, the entire thing being raised 15 feet above the ground.

In reality there are two wheels thirty feet apart. These twins are connected by iron rods and struts which do not approach nearer than twenty feet to the periphery. Outside of these rods the cars are hung and supported by steel bars of about five inches in thickness extending from one wheel to the other. Each wheel has for its outline a curved iron beam 25½ by 19 inches. Forty feet inside is another beam, forming a smaller circle. From these beams or circles extends the massive iron truss-work which holds them together.

The axle on which the great wheel turns is a steel bar 32 inches thick and 45 feet long. It is fastened to each of the twin wheels in a steel hub 16 feet in diameter. All of this great mass, the hubs and the two circles, is held together by 2½-inch steel rods arranged to run in pairs from the axle to spread 13 feet apart at the circumference.

There are thirty-six cars on the wheel, each capable of comfortably seating forty people. The cars are 27 feet long, 13 feet wide and 9 feet high, and each one weighs 13 tons.

The wheel, with its passengers, weighs 1,200 tons. The whole thing rests on two pyramidal towers at the axis. The towers are 140 feet high, forty by fifty feet at the base and six feet square at the top. Each tower has four feet resting on twenty-foot cube concrete foundations. Underneath these are crossbars of steel. The motive power comes from a 1,000 horse power steam engine under the wheel. It will find no difficulty in revolving the wheel and the passengers as fast as the latter want to go. There is an automatic air brake on, however, to regulate the speed and stop everything in case of danger. The wheel is moved by cogs on the periphery passing over a chain that looks like a mammoth bicycle chain. In the construction every precaution has been taken against accident.

The illumination of the wheel will be effected by arranging 300 incandescent lamps around the periphery on each side, and 360 lights on the cross beams. One hundred or more lamps will be placed in the form of rosettes on the axle. The legs and foundations will be wired for 500 lamps. A space of eighteen inches on the shaft has been reserved between the bearing and the hub for the collector rings, which will be similar to those used on alternating dynamos.

Current is to be furnished from a small plant in the boiler house, located about 400 feet from the wheel. The lighting plant will consist of a 150 horse-power Ball engine and an Edison dynamo.

In order to prevent accidents by starting the car before the gates or doors are closed a very novel electrical arrangement has been introduced. A six-point annunciator is mounted on the engine in full view of the engineer. Each drop is wired to one of the gates in such a manner that as soon as it is opened the pointer will indicate its position and the engineer will understand that the wheel cannot be put in motion.

The company has a plan under consideration for introducing a telephone system so that each car will be in direct communication with the engineer.

Ayrton and Mather's Electrostatic Voltmeter.

For the last three or four years Prof. Ayrton, in conjunction with Mr. Mather, has been experimenting with a view to the construction of a trustworthy and accurate electrostatic voltmeter for the measurement of high pressure. There can be no question about the great advantage of placing an electrostatic voltmeter directon high pressure mains, over the clumsy expedient frequently employed of wasting power in transforming down the pressure to suit the range of a low pressure hot wire voltmeter, which can only give a reading by wasting a good deal more power.

An increasing need is, therefore, felt for an electrostatic instrument prompt and accurate in its indications, and safe both from liability to internal injury caused by the pressure it measures and from risks of causing dangerous shocks to persons handling the instrument when in use. To fulfil the requirements of the engineer it should also have a bold scale, be suitable in form for fixing on a switchboard, and be quite unaffected by the cleaning of the glass or the proximity of other bodies, whether electrified or not.

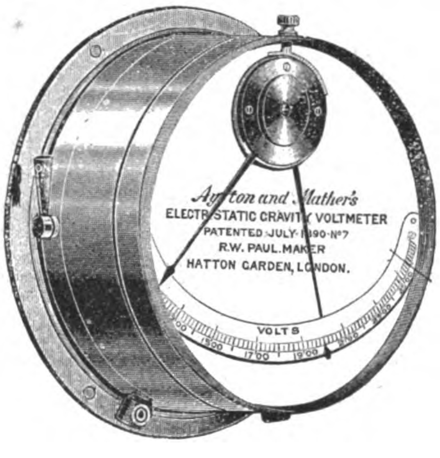


Fig. 1.

Many instruments were constructed by the inventors, some with spring or torsional control, others controlled by gravity; after exhaustive tests the style of instrument which fulfilled the conditions best was selected, and in its final form it is shown in Fig. 1, of which the following description is given by the *Electrical Review* (London):

The working parts of the instrument are shown diagrammatically in Fig. 2, in which the parts A, B, C are the fixed inductors, corresponding to the quadrant of an electrometer. These inductors are curved brass plates whose edges and corners are carefully rounded to prevent sparking. They are connected together by the plate D, and fixed in an inner case, from which they are highly insulated. The needle, E, F, consists of two thin curved aluminium plates concentric with the staff G, which carries them. These plates are drawn into the space between the inductors by the electrostatic attraction between them. Being curved, they have the advantage over flat plates in strength and lightness, their moment of inertia is small, so that the needle takes its position of equilibrium rapidly, and as the peripheries and spokes of the needle are made out of one piece of aluminium the electric conductivity is perfect, and the voltmeter accurately measures direct or alternating the pressures of any frequency. The needle is counterpoised by the hand and controlled by a weight attached to an arm on the staff so as to bring the hand to zero; it is finely pivoted in jewels, and works in a frame attached to the circular brass plate seen near the top of the dial. The working parts can thus be easily removed bodily. The needle is in connection with the dial, which carries the inner case containing the inductors, the latter being highly insulated. From the inductors an insulated spring reaches downwards alongside a similar spring attached to the inner case; these springs make contact with the terminals.

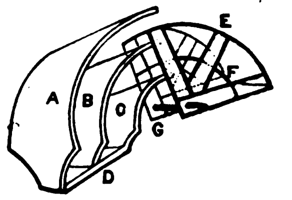

Fig. 2.

The dial is supported on ebonite pillars and surrounded by a bezil ring of ebonite, which prevents contact with the outer case, the latter is therefore entirely insulated from the circuit.

Each terminal, of which a section is shown in Fig. 3, is cased in ebonite, so that a person connecting up cannot receive shock from it. The hollow ebonite portion A, A, contains a brass block E, imbedded near its outer end and covered by an ebonite nipple; the block is tapped for the set screw F, which holds the wire in place. The part of A which projects into the case, into which it screws at B, contains a fuse of platinum silver, .001 inches in diameter, enclosed in a glass tube with metal caps to which it is connected. They make contact with the block E at one end and the spring cap D at the other. The cap D makes contact in turn with the connecting spring mentioned above. The fuses are therefore very easily replaced.

To enable the instrument to be easily disconnected from the mains when necessary, a switch is provided; the handle seen on the left side of the instrument is attached to a cam-shaft and turning it down raises the springs from the caps D of the terminals, and so disconnects the instrument from the mains; it then short-circuits the inductors and needle, bringing them to the same potential.

A spark gap is arranged inside the voltmeter; before the instrument is sent out it is tested at considerably above the working pressure for sparking between the needle and inductors, the gap is then adjusted, so that, in case of abnormal rise of pressure, sparking will occur at the gap and produce no damage.

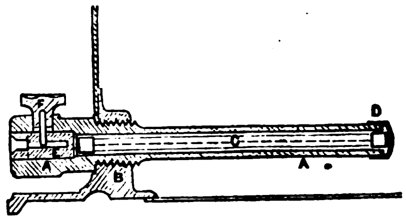

Fig. 3.

A device is provided whereby the engineer may see at a glance whether the working pressure is being maintained; it consists of an index below the scale (seen to the right of Fig. 1) adjustable by a crown wheel and pinion at the top of the instrument. It can be thus seen at a distance whether the pressure is right, that is, whether the hand and index coincide. When the index is turned as far as it will go to the left it clamps the needle for traveling.

The scale has a radius of 6 inches and a length of 10 inches, thus giving a bold open scale whose clearness is enhanced by the dead white silver of the dial. The external diameter of the instrument is 12 inches.

The instruments at present made are suitable for circuits at 500, 1,000, 2,000 and 2,400 volts, the range being very open near the working pressure. By differently shaping the inductors an equally divided scale may be obtained when desired.

The instruments are made by Mr. Paul, 44 Hatton Garden, and Leather Lane, London, E. C.

ON LIGHT AND OTHER HIGH FREQUENCY PHENOMENA.—V.

BY NIKOLA TESLA.*

Very high frequencies are of course not practicable with motors on account of the necessity of employing iron cores. But one may use sudden discharges of low frequency and thus obtain certain advantages of high frequency currents without rendering the iron core entirely incapable of following the changes and without entailing a very great expenditure of energy in the core. I have found it quite practicable to operate with such low frequency disruptive discharges of condenser alternating-current motors. A certain class of such motors which I advanced a few years ago, which contain closed secondary circuits, will rotate quite vigorously when the discharges are directed through the exciting coils. One reason that such a motor operates so well with these discharges is that the difference of phase between the primary and secondary currents is 90 degrees, which is generally not the case with harmonically rising and falling currents of low frequency. It might not be without interest to show an experiment with a single motor of the kind, inasmuch as it is commonly thought that disruptive discharges are unsuitable for such purposes. The motor is illustrated in Fig. 18. It comprises a rather large iron core *i* with slots on the top into which are imbedded thick copper washers *c c*. In proximity to the core is a freely movable metal disc D. The core is provided with a primary exciting coil C the ends *a* and *b* of which are connected to the terminals of the secondary S of an ordinary transformer, the primary P of the latter being connected to an alternating distribution circuit or generator G of low or moderate frequency. The terminals of the secondary S are attached to a condenser C which discharges through an air gap *d d* which may be placed in series or shunt to the coil C. When the conditions are properly chosen the disc D rotates with considerable effort and the iron core *i* does not get very perceptibly hot. With currents from a high frequency alternator, on the contrary, the core gets rapidly hot and the disc rotates with a much smaller effort. To perform the experiment properly it should be first ascertained that the disc D is not set in rotation when the discharge is not occurring at *d d*. It is preferable to use a large iron core and a condenser of large capacity so as to bring the superimposed quicker oscillation to a very low pitch or to do away with it entirely. By observing certain elementary rules I have also found it practicable to operate ordinary series or shunt direct-current motors with such disruptive discharges, and this can be done with or without a return wire.

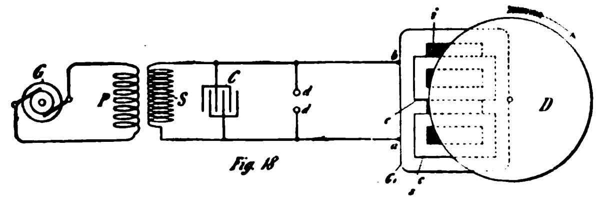

Fig. 18

OPERATING A MOTOR BY DISRUPTIVE DISCHARGES.

Among the various current phenomena observed perhaps the most interesting are those of impedence presented by conductors to currents varying at a rapid rate. In my first paper before the American Institute of Electrical Engineers, I described a few striking observations of this kind. Thus I showed that when such currents or sudden discharges are passed through a thick metal bar there may be points at the bar only a few inches apart which have a sufficient potential difference between them to maintain at bright incandescence an ordinary filament lamp. I have also described the curious behavior of rarefied gas surrounding a conductor to such sudden rushes of current. These phenomena have been since more carefully studied and one or two novel experiments of this kind are deemed of sufficient interest to be described here.

With reference to Fig. 19*a*, B and B_1 are very stout copper bars connected at their lower ends to plates C and C_1 respectively, of a condenser, the opposite plates of the latter being connected to the terminals of the secondary S of a high tension transformer, the primary P of which is supplied with alternating currents from an ordinary low frequency dynamo G or distribution circuit. The condenser discharges through an adjustable gap *d d* as usual. By establishing a rapid vibration it was found quite easy to perform the following curious experiment. The bars B and B_1 were joined at the top by a low voltage lamp l_3; a little lower was placed, by means of clamps *c c*, a 50-volt lamp l_2 and still lower another 100-volt lamp l_1, and finally at a certain distance below the latter lamp an exhausted tube T. By carefully determining the positions of these devices it was found practicable to maintain them all at their proper illuminating power. Yet they were all connected in multiple arc to the two stout copper bars and required widely different pressures. This experiment requires, of course, some time for adjustment but is quite easily performed.

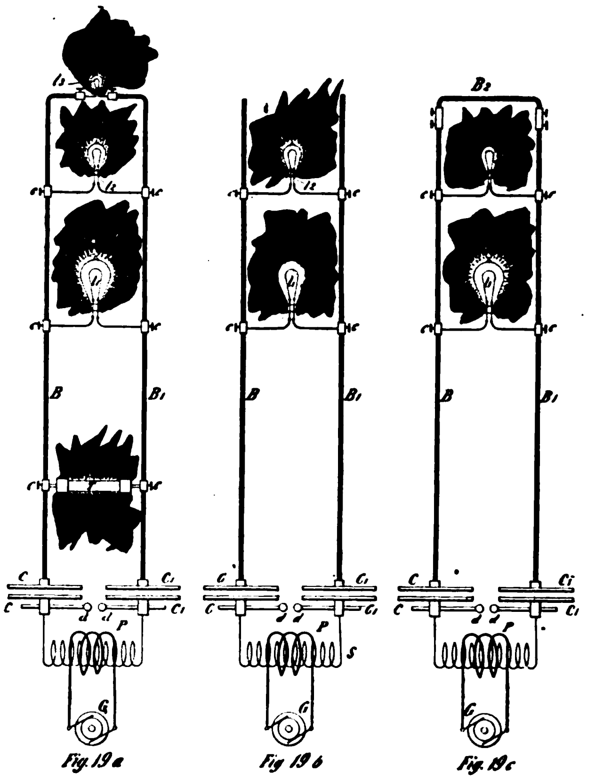

Fig. 19a Fig. 19b Fig. 19c

IMPEDENCE PHENOMENA.

In Figs. 19*b* and 19*c*, two other experiments are illustrated which, unlike the previous experiment, do not require very careful adjustments. In Fig. 20*b*, two lamps l_1 and l_2, the former a 100-volt and the latter a 50-volt, are placed in certain positions as indicated, the 100-volt lamp being below the 50-volt lamp. When the arc is playing at *d d* and the sudden discharges passed through the bars B B the 50-volt lamp will as a rule burn brightly, or at least this result is easily secured, while the 100-volt lamp will burn very low or remain quite dark, Fig. 19*b*. Now the bars B B may be joined at the top by a thick cross bar B_2 and it is quite easy to maintain the 100-volt lamp at full candle power while the 50-volt lamp remains dark, Fig. 19*c*. These results, as I have pointed out previously, should not be considered to be due exactly to frequency but rather to the rate of change, which may be great even with low frequencies. A great many other results of the same kind equally interesting, especially to those who are only used to manipulate steady currents, may be obtained, and they afford precious clues in investigating the nature of electric currents.

In the preceding experiments I have already had occasion to show some light phenomena, and it would be now proper to study these in particular; but to make this investigation more complete I think it necessary to first make a few remarks on the subject of electrical resonance which has to be always observed in carrying out these experiments.

ON ELECTRICAL RESONANCE.

The effects of resonance are being more and more noted by engineers and are becoming of great importance in the practical operation of apparatus of all kinds with alternating currents. A few general remarks may therefore be made concerning these effects. It is clear that if we succeed in employing the effects of resonance practically in the operation of electric devices the return wire will, as a matter of course, become unnecessary, for the electric vibration may be conveyed with one wire just as well, and sometimes even better, than with two. The question first to answer is, then, whether pure resonance effects are producible. Theory and experiment both show that such is impossible in nature, for as the oscillation becomes more and more vigorous the losses in the vibrating bodies and environing media rapidly increase and necessarily check the vibration which otherwise would go on increasing forever. It is a fortunate circumstance that pure resonance is not producible, for if it were there is no telling what dangers might not lie in wait for the innocent experimenter. But to a certain degree resonance is producible, the magnitude of the effects being limited by the imperfect conductivity and imperfect elasticity of the media or, generally stated, by frictional losses. The smaller these losses, the more striking are the effects. The same is the case in mechanical vibration. A stout steel bar may be set in vibration by drops of water falling upon it at proper intervals, and with glass, which is more perfectly elastic, the resonance effect is still more remarkable, for a goblet may be burst by singing into it a note of the proper pitch. The electrical resonance is the more perfectly attained the smaller the resistance or the impedence of the conducting path and the more perfect the dielectric. In a Leyden jar discharging through a short stranded cable of thin wires these requirements are probably best fulfilled, and the resonance effects are therefore very prominent. Such

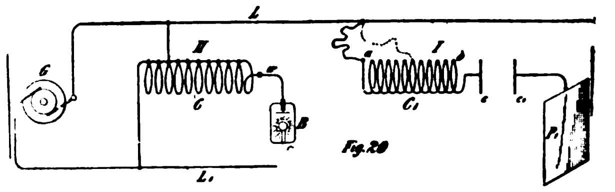

Fig. 20

PLAN FOLLOWED IN OBSERVING THE EFFECTS OF RESONANCE.

---

* A lecture delivered before the Franklin Institute at Philadelphia, Feb. 24, 1893, and before the National Electric Light Association at St. Louis, Mo., March 1, 1893.

is not the case with dynamo machines, transformers and their circuits, or with commercial apparatus in general in which the presence of iron cores complicates or renders impossible the action. In regard to Leyden jars, with which resonance effects are frequently demonstrated, I would say that the effects observed are often *attributed* but are seldom *due* to true resonance, for an error is quite easily made in this respect. This may be undoubtedly demonstrated by the following experiment. Take, for instance, two large insulated metallic plates or spheres, which I shall designate A and B, place them at a certain small distance apart and charge them from a frictional or influence machine to a potential so high that just a slight increase of the difference of potential between them will cause the small air or insulating space to break down. This is easily reached by making a few preliminary trials. If now another plate—fastened on an insulating handle and connected by a wire to one of the terminals of a high tension secondary of an induction coil, which is maintained in action by an alternator (preferably high frequency)—is approached to one of the charged bodies A or B, so as to be nearer to either one of them, the discharge will invariably occur between them; at least it will if the potential of the coil in connection with the plate is sufficiently high. But the explanation of this will soon be found in the fact that the approached plate acts inductively upon the bodies A and B, and causes a spark to pass between them. When this spark occurs, the charges, which were previously imparted to these bodies from the influence machine, must needs be lost, since the bodies are brought in electrical connection through the arc formed. Now this arc is formed whether there be resonance or not. But even if the spark would not be produced, still there is an alternating E. M. F. set up between the bodies when the plate is brought near one of them; therefore the approach of the plate, if it *does* not always actually, will at any rate, *tend*, to break down the air space by inductive action. Instead of the spheres or plates A and B we may take the coatings of a Leyden jar with the same result, and in place of the machine, which is a high frequency alternator preferably, because it is more suitable for the experiment and also for the argument, we may take another Leyden jar or battery of jars. When such jars are discharging through a circuit of low resistance the same is traversed by currents of very high frequency. The plate may now be connected to one of the coatings of the second jar, and when it is brought near to the first jar, just previously charged to a high potential from an influence machine, the result is the same as before, and the first jar will discharge through a small air space upon the second being caused to discharge. But both jars and their circuits need not be tuned any closer than a basso profundo is to the note produced by a mosquito, as small sparks will be produced through the air space, or at least the latter will be considerably more strained owing to the setting up of an alternating E. M. F. by induction, which takes place when one of the jars begins to discharge. Again another error of a similar nature is quite easily made. If the circuits of the two jars are run parallel and close together, and the experiment has been performed of discharging one by the other, and now a coil of wire be added to one of the circuits, whereupon the experiment does not succeed, the conclusion that this is due to the fact that the circuits are now not tuned would be far from being safe. For the two circuits act as a condenser coatings, and the addition of the coil to one of them is equivalent to bridging them, at the point where the coil is placed, by a small condenser, and the effect of the latter might be to prevent the spark from jumping through the discharge space by diminishing the alternating E. M. F. acting across the same. All these remarks, and many more which might be added but for fear of wandering too far from the subject, are made with the pardonable intention of cautioning the unsuspecting student, who might gain an entirely unwarranted opinion of his skill when seeing every experiment succeed; but they are in no way thrust upon the experienced as novel observations.

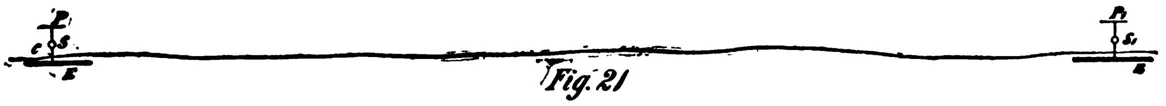

Fig. 21

ENERGY TRANSMISSION TO ANY DISTANCE WITHOUT WIRES.

In order to make reliable observations of electric resonance effects it is very desirable, if not necessary, to employ an alternator giving currents which rise and fall harmonically, as in working with make and break currents the observations are not always trustworthy, since many phenomena which depend on the rate of change may be produced with frequencies widely different. Even when making such observations with an alternator one is apt to be mistaken. When a circuit is connected to an alternator there are an infinite number of values for capacity and self-induction which, in conjunction, will satisfy the condition of resonance. So there are in mechanics an infinite number of tuning forks which will respond to a note of a certain pitch, or loaded springs which have a definite period of vibration. But the resonance will be most perfectly attained in that case in which the motion is effected with the greatest freedom. Now in mechanics, considering the vibration in the common medium—that is, air—it is of comparatively little importance whether one tuning fork be somewhat larger than another, because the losses in the air are not very considerable. One may of course enclose a tuning fork in an exhausted vessel and by thus reducing the air resistance to a minimum obtain better resonant action. Still the difference would not be very great. But it would make a great difference if the tuning fork were immersed in mercury. In the electrical vibration it is of enormous importance to arrange the conditions so that the vibration is effected with the greatest freedom. The magnitude of the resonance effect depends, under otherwise equal conditions, on the quantity of electricity set in motion or on the strength of the current driven through the circuit. But the circuit opposes the passage of the currents by reason of its impedence and therefore, to secure the best action it is necessary to reduce the impedence to a minimum. It is impossible to overcome it entirely, but merely in part, for ohmic resistance cannot be overcome. But when the frequency of the impulses is very great, the flow of the current is practically determined by self-induction. Now self-induction can be overcome by combining it with capacity. If the relation between these is such that at the frequency used they annul each other, that is, have such values as to satisfy the condition of resonance and the greatest quantity of electricity is made to flow through the external circuit, then the best result is obtained. It is simpler and safer to join the condenser in series with the self-induction. It is clear that in such combinations there will be, for a given frequency, and considering only the fundamental vibration, values which will give the best result with the condenser in shunt to the self-induction coil—of course more such values than with the condenser in series. But practical conditions determine the selection. In the latter case in performing the experiments one may take a small self-induction and a large capacity or a small capacity and a large self-induction, but the latter is preferable, because it is inconvenient to adjust a large capacity by small steps. By taking a coil with a very large self-induction the critical capacity is reduced to a very small value, and the capacity of the coil itself may be sufficient. It is easy, especially by observing certain artifices, to wind a coil through which the impedence will be reduced to the value of the ohmic resistance only, and for any coil there is, of course, a frequency at which the maximum current will be made to pass through the coil. The observation of the relation between self-induction, capacity and frequency is becoming important in the operation of alternate current apparatus, such as transformers or motors, because by a judicious determination of the elements the employment of an expensive condenser becomes unnecessary. Thus it is possible to pass through the coils of an alternating current motor under the normal working conditions the required current with a low E. M. F. and do away entirely with the false current, and the larger the motor the easier such a plan becomes practicable; but it is necessary for this to employ currents of very high potential or high frequency.

In Fig. 20 I is shown a plan which has been followed in the study of the resonance effects by means of a high frequency alternator. C is a coil of many turns, which is divided in small separate sections for the purposes of adjustment. The final adjustment was made sometimes with a few thin iron wires (though this is not always advisable), or with a closed secondary. The coil C is connected with one of its ends to the line L from the alternator G and with the other end to one of the plates *c* of a condenser $c\ c_1$, the plate (c_1) of the latter being connected to a much larger plate P_1. In this manner both capacity and self-induction were adjusted to suit the dynamo frequency.

As regards the rise of potential through resonant action, of course theoretically it may amount to anything since it depends on self-induction and resistance and since these may have any value. But in practice one is limited in the selection of these values, and besides these there are other limiting causes. One may start with, say, 1,000 volts and raise the E. M. F. to fifty times that value, but one cannot start with 100,000 and raise it to ten times that value because of the losses in the media, which are great, especially if the frequency is high. It should be possible to start with, for instance, two volts from a high or low frequency circuit of a dynamo and raise the E. M. F. to many hundred times that value. Thus coils of the proper dimensions might be connected each with only one of its ends to the mains from a machine of low E. M. F., and though the circuit of the machine would not be closed in the ordinary acceptance of the term, yet the machine might be burned out if a proper resonance effect would be obtained. I have not been able to produce, nor have I observed with current from the dynamo machine, such great rises of potential. It is possible, if not probable, that with currents obtained from apparatus containing iron the disturbing influence of the latter is the cause that these theoretical possibilities cannot be realized. But if such is the case I attribute it solely to the hysteresis and Foucault current losses in the core. Generally it was necessary to transform upward, when the E. M. F. was very low, and usually an ordinary form of induction coil was employed, but sometimes the arrangement illustrated in Fig. 20 II has been found to be convenient. In this case a coil C is made in a great many sections, a few of these being used as the primary. In this manner both primary and secondary are adjustable. One end of the coil is connected to the line L_1 from the alternator, and the other line L is connected to the intermediate point of the coil. Such a coil with adjustable primary and secondary will be found also convenient in experiments with the disruptive discharge. When true resonance is obtained the top of the wave must, of course, be on the free end of the coil as, for instance, at the terminal of the phosphorescence bulb B. This is easily recognized by observing the potential of a point on the wire *w* nearer to the coil.

In connection with resonance effects and the problem of transmission of energy over a single conductor, which was previously considered, I would say a few words on a subject which constantly fills my thoughts and which concerns the welfare of all. I mean the transmission of intelligible signals, or perhaps even power, to any distance without the use of wires. I am becoming daily more convinced of the practicability of the scheme; and though I know full well that the great majority of scientific men will not believe that such results can be practically and immediately realized, yet I think that all consider the developments in recent years by a number of workers to have been such as to encourage thought and experiment in this direction. My conviction has grown so strong that I no longer look upon this plan of energy or intelligence transmission as a mere theoretical possibility, but as a serious problem in electrical engineering, which must be carried out some day. The idea of transmitting intelligence without wires is the natural outcome of the most recent results of electrical investigations. Some enthusiasts have expressed their belief that telephony to any distance by induction through the air is possible. I cannot stretch my imagination so far, but I do firmly believe that it is practicable to disturb by means of powerful machines the electrostatic condition of the earth and thus transmit intelligible signals and perhaps power. In fact, what is there against the carrying out of such a scheme ? We now know that electric vibration may be transmitted through a single conductor. Why then not try to avail ourselves of the earth for this purpose? We need not be frightened by the idea of distance. To the weary wanderer counting the mile posts the earth may appear very large, but to that happiest of all men, the astronomer, who gazes at the heavens and by their standard judges the magnitude of our globe, it appears very small.

And so I think it must seem to the electrician, for when he considers the speed with which an electric disturbance is propagated through the earth all his ideas of distance must completely vanish.

A point of great importance would be first to know what is the capacity of the earth? and what charge does it contain if electrified? Though we have no positive evidence of a charged body existing in space without other oppositely electrified bodies being near, there is a fair probability that the earth is such a body, for by whatever process it was separated from other bodies—and this is the accepted view of its origin—it must have retained a charge, as occurs in all processes of mechanical separation. If it be a charged body insulated in space its capacity should be extremely small, less than one-thousandth of a farad. But the upper strata of the air are conducting, and so, perhaps, is the medium in free space beyond the atmosphere, and these may contain an opposite charge. Then the capacity might be incomparably greater. In any case it is of the greatest importance to get an idea of what quantity of electricity the earth contains. It is difficult to say whether we shall ever acquire this necessary knowledge, but there is hope that we may, and that is, by means of electrical resonance. If ever we can ascertain at what period the earth's charge, when disturbed, oscillates with respect to an oppositely electrified system or known circuit, we shall know a fact possibly of the greatest importance to the welfare of the human race. I propose to seek for the period by means of an electrical oscillator, or a source of alternating electric currents. One of the terminals of the source would be connected to earth as, for instance, to the city water mains, the other to an insulated body of large surface. It is possible that the outer conducting air strata or free space contains an opposite charge and that, together with the earth, they form a condenser of very large capacity. In such case the period of vibration may be very low and an alternating dynamo machine might serve for the purpose of the experiment. I would then transform the current to a potential as high as it would be found possible and connect the ends of the high tension secondary to the ground and to the insulated body. By varying the frequency of the currents and carefully observing the potential of the insulated body, and watching for the disturbance at various neighboring points of the earth's surface, resonance might be detected. Should, as the majority of scientific men in all probability believe, the period be extremely small, then a dynamo machine would not do and a proper electrical oscillator would have to be produced, and perhaps it might not be possible to obtain such rapid vibrations. But whether this be possible or not, and whether the earth contains a charge or not, and whatever may be its period of vibration, it certainly is possible—for of this we have daily evidence—to produce some electrical disturbance sufficiently powerful to be perceptible by suitable instruments at any point of the earth's surface.

Assume that a source of alternating currents s be connected, as in Fig. 21, with one of its terminals to earth (conveniently to the water mains) and with the other to a body of large surface P. When the electric oscillation is set up there will be a movement of electricity in and out of P, and alternating currents will pass through the earth, converging to, or diverging from, the point C where the ground connection is made. In this manner neighboring points on the earth's surface within a certain radius will be disturbed. But the disturbance will diminish with the distance, and the distance at which the effect will still be perceptible will depend on the quantity of electricity set in motion. Since the body P is insulated, in order to displace a considerable quantity the potential of the source must be excessive, since there would be limitations as to the surface of P. The conditions might be adjusted so that the generator or source s will set up the same electrical movement as though its circuit were closed. Thus it is certainly practicable to impress an electric vibration at least of a certain low period upon the earth by means of proper machinery. At what distance such a vibration might be made perceptible can only be conjectured. I have on another occasion considered the question how the earth might behave to electric disturbances. There is no doubt that, since in such an experiment the electrical density at the surface could be but extremely small considering the size of the earth, the air would not act as a very disturbing factor and there would be not much energy lost through the action of the air which would be the case if the density were great. Theoretically, then, it could not require a great amount of energy to produce a disturbance perceptible at great distance, or even all over the surface of the globe. Now it is quite certain that at any point within a certain radius of the source s a properly adjusted self induction and capacity device can be set in action by resonance. But not only can this be done, but another source s_1 Fig. 21, similar to s, or any number of such sources can be set to work in synchronism with the latter and the vibration thus intensified and spread over a large area, or a flow of electricity produced to or from the source s_1 if the same be of opposite phase to the source s. I think that beyond doubt it is possible to operate electrical devices in a city through the ground or pipe system by resonance from an electrical oscillator located at a central point. But the practical solution of this problem would be of incomparably smaller benefit to man than the realization of the scheme of transmitting intelligence or perhaps power to any distance through the earth or environing medium. If this is at all possible, distance does not mean anything. Proper apparatus must first be produced by means of which the problem can be attacked and I have devoted much thought to this subject. I am firmly convinced that it can be done and hope that we shall live to see it done.

(To be continued.)

The Electrically Lighted Fountains at the Exposition.

A correspondent of the Buffalo *Times* writes enthusiastically of the electrically illuminated fountains that form such an attractive feature of the spectacular attractions at the Columbian Exposition. He says:

"Of all the contrivances of man for the creation of beautiful effects this electric fountain is the most wonderful. It is impossible for me or any one else to describe the glorious spectacle. It is something that must be seen to be appreciated. But imagine, if you can, a bouquet of gorgeous water flowers rising to a height of 150 feet and changing their colors as they rise and fall; showers of rubies, pearls and amethysts; great sheaves of golden wheat; ferns in columns and sprays of water greener than moss in the woods. But how do they introduce the color effects? This operation is simple. By each search light stands a six-leafed fan arrangement attached to an upright spindle. Each leaf, which is of glass, has a different color. One is red, another green, a third blue, a fourth orange, a fifth sea-green, a sixth ruby. The operator may throw on any one of these colors, which is instantly reflected through the stream and in every drop of spray or particle of mist overhead. He may cause the fan to revolve and thus change the colors with kaleidoscopic rapidity. He may paint one set of streams in red and another in ruby. He may surround a red and vivid central palm with a circlet of a dozen golden wheat sheaves. He may cause a column of water to rise in a sea-green pillar and then to burst into a shower of rubies and so on."

The water for this display is forced through pipes from the pumping station near Machinery Hall. There are four huge pumps in operation there, but the leviathan of the lot is used for the fountain. The daily capacity of the four pumps is forty millions of gallons. The fountain pump, says the writer, "rises before the eye like a six-story house. By actual measurement it is fifty-one feet high. It is what is known as a vertical compound low duty pumping engine. The high pressure cylinder is two and a half and the low pressure cylinder five feet in diameter. The stroke, fifty-two to the minute, is five feet long. . . . In the eastern end of Machinery Hall is the generating plant for the electric light part of this magical fountain. This consists of four big dynamos, set in a row. They are painted white, the fields of their generating cylinders are wound with white cord, and the switchboard from which they are controlled is of white marble. These four dynamos generate the current which throws a fierce light from the reflectors upon the rising columns of water. A thousand horse power is converted into light for the illumination of the fountains. There are two engines in this plant, and one of them of the cross compound type, cylinders 20 inches and 38 inches, running at 224 revolutions per minute, develops 600 horse power and is said to be the largest high speed engine in the country. This pair of engines, painted white like the remainder of the plant, are as graceful and perfect in their operation as if they were built for beauty and not for power. While not in use for the fountains the engines charge the batteries of the fleet of electric launches which run about the lagoons."

Dead-Weight.

A great deal of the expense of electric traction is due to the effect of the dead-weight of carriage that it is supposed to be necessary to carry. There is first the actual material itself perhaps uselessly expended, there is the added strength and weight of motor required, and the added size of locomotive by reason of these two. Then the added cost of capital for plant, and added expense in maintenance. Now let us put it to the electrical engineers who build electrical railways: Is it really necessary to have all this dead-weight besides the passengers? We must remember that questions of extreme efficiency have only lately had their full play. Hitherto, anything that would stand well and do its work, even if inefficient, was enough. The old coach, with its paraphernalia of springs, trappings and gilt, was not designed for special lightness nor on the best scientific principles. The railway wagons were but modified coaches, and to-day the influence of the coachbuilders is paramount; and in trams and electric cars the same old fashion of building cars is followed with but little variation. The Pullman car, a marvel of convenience, is also extremely heavy. It is not so with one other carriage now greatly used—the bicycle. Here every endeavor of scientific ingenuity has been expended to obtain lightness of rolling-stock, and 25 lbs. or 30 lbs. dead weight per person is not uncommon. The speeds, moreover, that this apparently frail structure will stand are often nearly 20 miles an hour, and not over smooth rails, but over the usual broad roads. The question may be suggestively asked: If we are going to have electric cars, can we not do away with much of the dead-weight? And possibly the answer might be more satisfactorily solved—we give the suggestion tentatively—if the cars were designed not by coachbuilders, but by those, like the bicycle builders, who have devoted their lives to the reduction in scientific principles of the dead-weight. A structure, as is well known, need not be less stiff, less strong, if the material is saved where it is not required; and the fact that cars for bearing the weight of so many persons could, if desired, be designed of far less weight should lead those who are considering the electric railways of the future to consider not only the efficiency of their dynamos and engines, not only the equalization of loads, but the reduction to the lowest limit compatible with safety of the dead-weight to be hauled. We think the question is worthy of study.—*Electrical Engineer*, London.

The Illinois Lamp Company and Mr. Schaefer.

The troubles of the Illinois Lamp Company and Mr. John F. Schaefer, the former superintendent, have been settled through the intervention of Mr. B. E. Sunny of the General Electric Company.

The latter company has bought out the stock, good will, patents, etc., of the Illinois Lamp Company for about $1,500. The Illinois company discontinues its proceedings against Mr. Schaefer, who enters the employ of Mr. Sunny for one year at a good salary.

The Battle Royal at Detroit.

The success or failure of the present plan of the city of Detroit to erect and operate a lighting plant of its own, and to do it economically, is a matter of more than ordinary interest to electrical business men throughout the country.

The general question of the desirability of municipal plants is a broad one, and ELECTRICITY has already given its opinion on the subject. But for a town situated as Detroit is there can be but one opinion among unprejudiced men. The town buys light; it pays out a large sum of money for it; it is entitled to competition, and failing to get the benefits of competition, the only thing it can do in justice to its taxpayers is to erect a city plant and operate it.

As in other matters where the feelings of the General Electric Company are likely to be hurt, our discreet contemporaries have ignored the battle royal which has been in progress in Detroit, and which is not yet finally decided. But the regular readers of ELECTRICITY have been kept posted.

It will be remembered that some months ago the matter of a new contract for the city lighting came up. The Detroit Electric Light and Power Company has had the field to itself, and its present contract expires July 1. The price has been high and the service very bad.

A year or two ago the Michigan Legislature passed a law enabling towns to own lighting plants, but Detroit was barred out through the efforts of Messrs. Fitzgerald and McDonald.

This year Mayor Pingree, after becoming convinced that there would be no competition for the city contract, went before the Legislature and after a hard struggle got the limitations removed. Then followed a bitter fight in the Council, the bribery of several aldermen, the arrest of Manager Fitzgerald, and finally the complete victory of the Mayor.

Manager Fitzgerald made the effort of his life, and finding the tide turning against him, sent for those old campaigners, Mr. Richard McDonald and Mr. Ellery Garfield, who came promptly and took personal charge of the army of special agents. Boodle was plenty, and it is said some of the aldermen got as much as $800 apiece. And although Mayor Pingree is an able fighter, he would surely have been beaten by McDonald and Garfield had not a stroke of good luck come his way. An alderman who had been "approached" by Fitzgerald came voluntarily to the Mayor and surrendered the boodle which Fitzgerald had given him "on account" the day before the question came up in the board for action. Mayor Pingree waved this boodle before the aldermen just previous to the vote, and with wholesome effect—they were afraid to deliver the goods which they had sold.

The appointment of a Lighting Commission followed, and it is expected that bids will be called for within a few weeks for a plant to cost all told about $600,000. Contrary to general expectations, Mr. Frank B. Rae was not appointed as engineer by the Lighting Commission, the place having been given to Mr. Alexander Dow, of Chicago, who has been for years prominently identified with a large manufacturing company.

The next question to be settled in Detroit is "How shall the city be lighted pending the completion of the city plant?" The contract expires July 1, and it has been intimated that the Detroit Electric Light and Power Company will demand a price large enough to pay for their entire plant for four months' service.

Mayor Pingree does not look with approval upon any such scheme, and has several plans by which the city may make its power felt.

Our readers will be promptly informed of further developments.

* * *

An Error at the Start.

We trust that the future official acts of the Detroit Lighting Commission will be a good deal further beyond criticism than the appointment of their electrical engineer; and this without any reflection whatever upon Mr. Dow. His appointment was just as surely an improper one as would have been the placing of a manufacturer of apparatus on the commission itself.

The proper man for that position would be some one who has never been interested in the sale of the apparatus of any company which is to be a competitor for the plant.

There are dozens of such men to be had, men of ability and experience equal at least to Mr. Dow's.

If the commission desires to place itself beyond criticism at once, it will secure the services of two consulting engineers, who shall pass upon Mr. Dow's work; and no one should be more anxious for such an arrangement than Mr. Dow himself.

The State of Michigan is not barren of electrical talent, and we beg to suggest to the commission the name of a gentleman who is eminently qualified, both by ability and by his freedom from entangling business alliances, to fill such a position creditably—Prof. H. S. Carhart, of Ann Arbor University.

The appointment of Prof. Carhart and Mr. Rae would clear the atmosphere at once.

* * *

Electric Heating Applications.

The subject of electric heating has been vigorously pursued recently, as the latest application of this system will show. This is a method of burning brick by electricity and dispensing with the ordinary kiln. The process, which has been put to a practical test, is extremely simple and the bricks so produced are pronounced harder and better than those of the usual manufacture, and they are also produced more cheaply and in a much shorter time.

The apparatus consists of a number of electrically connected iron molds in which the clay is placed and on which covers are securely fastened. The molds and their contents are then heated by a current which completes the burning in about three hours, after which the covers are automatically removed and the finished bricks are dumped out to cool.

This system of heating permits an intense degree of heat to be applied which is unattainable in a kiln and reduces the time necessary for burning to a fraction of the time formerly necessary. This process in some respects seems well adapted to burning all kinds of clay wares, as besides the intensity of the heat it also permits of accurate regulation, which is an essential condition for most earthenware manufacture, as the least defect in any flue of a kiln will ruin all the goods in the vicinity of that flue.

In burning many wares it is also a matter of extreme care to reduce the heat very gradually and evenly after the burning is finished in order to avoid cracking the goods, and in this respect an electric heater would have a great advantage over the kiln. There is, of course, no pressure exerted on the molds by the clay as it shrinks in volume during the burning.

* * *

Safe Medical Apparatus. The question of the safety of utilizing the currents from central stations in connection with electro-medical apparatus has been raised for discussion frequently, and the general opinion is that any danger attending this practice is not probable, but it must be admitted that although remote it is not impossible for the patient, in case of certain accidents, to receive a considerable overdose of current. The danger lies chiefly in the direction of imperfect insulation and the possibility of contact with other lines carrying much higher voltages. The mains should certainly not be used for medical use, unless the very best systems of automatic cut-outs are employed so that any disturbance on the line will cut off the current altogether.

There is no doubt but that patients generally would prefer to avoid the possibility of electrocution however remote, and with the very best of apparatus the treatment by electricity should only be administered by a physician thoroughly familiar with its use.

* * *

IT IS doubtful if the visit of Mr. E. I. Garfield to Detroit in the interest of his friends Fitzgerald and McDonald was productive of much good. There are a great many respectable business men in that city who would condemn, without further consideration, anything in which Mr. Garfield is interested.

* * *

WE WONDER why it is that Mr. E. I. Garfield, at one time Controller of the city of Detroit and now secretary of the General Electric Company, fails to register at any hotel when he visits that city, but sneaks in and out of town like a fugitive from justice. Can any one tell?

* * *

THERE can be no impropriety in our reminding Mr. Alexander Dow, electrical engineer for the Detroit Lighting Commission and some time agent for the Brush Electric Company, that we are looking at him.

An inventor in Lynn proposes to sprinkle the streets of that city with an apparatus built on an electric car, the sprinkler itself being in many respects similar to those with which the ordinary water cask on wheels is equipped.

Lieut. Spencer and the Westinghouse Exhibit.

Exhibitors in the Electricity Building of the World's Fair are having a good deal of quiet fun over the frantic efforts made by Lieut. E. J. Spencer, who has charge of the General Electric Company's exhibit, to have a portion of the Westinghouse exhibit abolished as a common nuisance.

It appears that after space had been allotted to the various companies it was discovered that no provision had been made for filling the large space on the south wall of the building over the gallery, and that without decoration of some kind it would not be at all in keeping with the rest of the building. This wall space was accordingly offered to the General Electric Company, who declined to use it, as did three or four others afterwards. Finally it was offered to the Westinghouse Company, who accepted it promptly.

Workmen have been busy for some days arranging the display, which will consist of a figure of Columbus and some scroll-work in incandescent lamps, and an illuminated sign of the Westinghouse Company of mammoth proportions. It was evidently feared that the chance visitor would consider the entire building as an exhibit of the Westinghouse Company and the General Electric Company merely a dependency of the former.

At any rate, Lieut. Spencer objected. Petitions were circulated among exhibitors asking for the removal of the sign, but they got few signatures—not over a dozen all told. Then Mr. Spencer wrote to Prof. Barrett, as the story goes, and threatened to withdraw the exhibit of the General Company. He received a vigorous reply, stating that if any such thing were attempted the management would cancel all the passes of Mr. Spencer and his employees, and would run the exhibit themselves.

The sign remains, and exhibitors, particularly those in the gallery, consider it a welcome addition to the show in the building.

Observations.

Chicago and the World's Fair.

A representative of ELECTRICITY who recently spent a few days in Chicago observed—

That the town is being run wide open.

That the police interpose no objection to the enjoyment of the multitude, whatever direction the enjoyment may take.

That the show in its entirety is the grandest exhibition the world has ever seen, and that Chicago has eminent reason to be satisfied with herself.

That the Bowery is tameness itself compared with the Midway Plaisance, and that even the babes of the exhibiting tribes know enough to reach for American coin.

That the Western Electric Company's exhibit is the most attractive one in the Electricity Building; that the Westinghouse exhibit comes next, and the General Electric Company is in third place.

That the curtains in front of Newspaper Row will dissolve in a damp atmosphere.

That the masses will leave the most instructive exhibits, like Prof. Gray's telautograph, and crowd each other to get near the "fake" electrical hand organ, which is driving exhibitors in the west gallery to insanity.

That that hand organ has got to go.

That Dr. Owen, who sells "electric" belts, is very much in evidence, whiskers and all; and that his exhibit should not have been allowed within one mile of the Electricity Building.

That by allotting space to various "electro-medical" exhibits of a questionable nature, the management has assisted in the humbugging of the public.

That the Ferris Wheel is the biggest thing at the Fair, and that when it finally lands at Coney Island, where it naturally belongs, New Yorkers who have not already seen it in the Midway will be amazed.

That the statement of a New York paper that there is nothing new in the conception of this wheel is nonsense; that the wheel is a notable triumph of engineering skill, and ought to make a fortune for its inventor.

That the hotels in Chicago are trying to pay off all their mortgages out of the profits of this season's business.

That the new hotels that failed to advertise are not turning many guests away.

That the restaurants throughout the city have maintained their regular rates, which have never been high.

That intending visitors who select the Hotel Ingram, kept by Warren Leland, will make no mistake.

That Chicago's surface cars, for the purpose of getting about in the business part of the town, are about as useful to a stranger as so many ox teams.

That the huts of the African and South Sea Island tribes on the Midway, illuminated by incandescent lights, must cause even their inhabitants to smile.

That the entertainment provided at the Trocadero is the best thing of the kind ever heard in this country; that New York has never yet been able to maintain anything of the kind, and that the audiences are far more respectable than those which gather at a mixed entertainment in New York—even at the Vaudeville Club.

That the grand show is now complete, open every day in the week from 7 A. M. to 11 P. M., and that every citizen who can raise the money, even if he has to borrow it, should go and see it and stay as long as possible.

World's Fair Notes.

The exhibit of the Bryant Electric Company, which is illustrated in this issue, is one of the most artistic exhibits in the gallery of the Electricity Building. It is composed of a number of their well-known switches mounted on a dark background and very artistically arranged to form an outline for a smaller board on which are mounted very neat designs for fuse blocks and sockets. As will be noticed, the railing is composed of different parts of their appliances. The display was designed and constructed by the Grier brothers, who are the Western agents for the Bryant Company.

The Belknap Motor Company's exhibit occupies a prominent position on the east side of the main floor of the Electricity Building. The exhibit is exceedingly novel and attractive, especially to the ordinary visitor. The practical application of the electric motor as shown in the display appeals to their nature, as is proven by the quaint remarks dropped within hearing of the attendants. The company have twenty-six motors in operation. Some of them are used in running coffee mills, while others are utilized to run dynamos and exhaust fans. A very neat electrical sign has been erected on one side of the booth which is attracting considerable attention. Their electric drill with magnetic grip is very interesting.

The electrical exhibit of the British Government has arrived and is being placed in position in the Electricity Building. It consists principally of a number of historical instruments and includes the original telegraph machines made by Wheatstone and Cooke. The intention of the display of instruments is to convey to the mind the course pursued in developing the telegraph to its present state. A large number of sections of cable are exhibited which show the action of different climates and currents of water on insulation. The exhibit as a whole is a very creditable one for the Government sending it.

The Western Electric Company's large display continues to be one of the leading attractions in the Electricity Building. The electric scenic theatre was opened this week and commanded the attention of a portion of the large crowd that congregates around the company's space.

The decision of the directors to keep the Fair open every evening instead of only three evenings in the week has been favorably received by both exhibitors and visitors. A number of the displays, especially those in the Electricity Building, can only be shown to advantage after dark. Since the order went into effect the construction department has been overwhelmed with orders for more incandescent lights, showing that the exhibitors expect a largely increased attendance at night.

The electric buoys which are to light the water way between the Park and the city pier have all been anchored in position and connected up by a double cable. It is expected that current will be turned on during the coming week. With the lamps illuminating the water there will be little danger of the many boats plying between the city and the Exposition grounds colliding with each other.

The Action of Compound Dynamos When Run in Parallel.

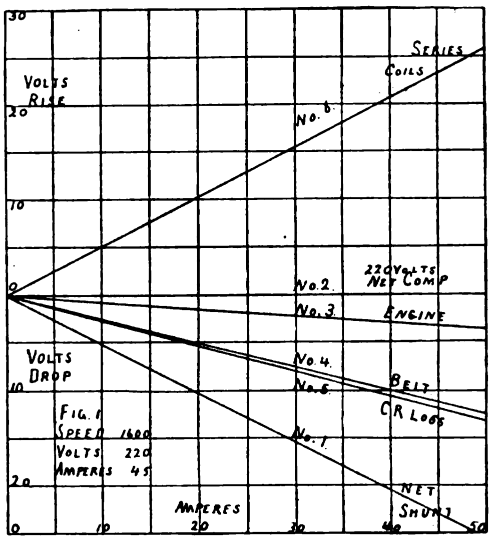
BY WILLIAM L. PUFFER, S. B.*

While arranging some details of the wiring plan for connecting up two compounded railroad generators so that they could be tested for commercial efficiency, while under the conditions of full load, by one of the purely electrical methods, my attention was drawn to the fact that the usual method of adjusting such dynamos so that they would give a constant potential at their terminals irrespective of the current flowing could not be a correct one unless the machines were exactly alike in all respects.

The general practice is to over-compound such generators, and then to experimentally shunt the series coils with a German silver ribbon until the desired "0 per cent. rise" is obtained; this is well enough for a single dynamo, but when two or more are in parallel, with their series coils also in parallel, the German silver shunts do not in any way aid the different dynamos in equalizing their load, and any original structural difference will cause the load to divide unequally. I found that in all of the power plants that I could then visit (winter of 1890-91) there was very decided evidence of this tendency to unequal division of the load, and it could readily be seen that some machines were always taking more than their share of an increase of load and tending to do too little when the load fell off. There seemed to be a very common knowledge of the trouble in making the dynamos work well together, but there seemed to be no attempt to help the matter, or, as far as I could find, any knowledge of where the fault was.

A year ago the Thomson-Houston Electric Company was so kind as to loan the Institute a pair of similar over-compounded motor-type dynamos which had been adjusted for "0 per cent. rise"; these dynamos were similar to the power generators of that company, and enabled me to make a study of the action of compound generators connected in parallel. The dynamos were belt driven from the main shaft in the dynamo room of the Physical Department and were under good average running conditions. A short piece of shafting was arranged so that by slipping the pulleys slightly the two armature shafts could be mechanically connected, and therefore must at all times be at the same speed. Suitable water resistances connected to each machine were used for varying the output of the armatures. Double-pole jack-knife switches of the type generally used were provided for connecting the two dynamos in parallel. A dead-beat ammeter was placed in each armature circuit, and an Ayrton & Perry spring ammeter in the equalizing wire; a Weston voltmeter was used in connection with pressure wires to measure the voltage of either armature.

Considering first the action of a single shunt dynamo driven by a belt from an engine doing no other work, if now the load be gradually increased to the maximum amount that can be safely carried, and if from time to time simultaneous values of the current and voltage be taken and plotted as in Fig. 1, Curve 1—for want of a better name let us call this the *net* characteristic curve of the combination—this curve would be a horizontal line (Curve 2) if it were not for the sum of a number of actions all of which tend to lower the electromotive force. Beginning at the engine there is the usual fall of speed as the load increases, due simply to the action of the governor (Curve 3); the dynamo pulley lags behind more and more on account of the increasing slip of the belt as the transmitted power becomes greater (these two changes are plotted in Curve 4); in the dynamo armature there are the usual demagnetizing reactions which lower the electromotive force; and finally there is the fall of potential in the armature wires as well as all the necessary leads, fuses, ammeters and connections up to the distribution point or bus bar where the voltmeter was connected (Curve 5). These separate losses may be plotted separately, and their sum will equal the amount that the net characteristic will fall below a horizontal line.

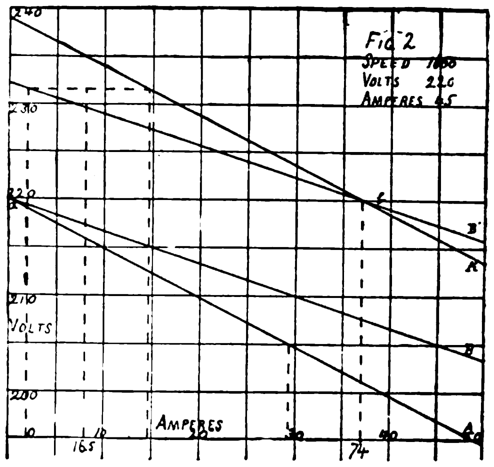


Inasmuch as the net characteristic in this combination is a very drooping one, it would be necessary to use hand or automatic means of adjusting the voltage as the current changes so as to keep the mains at the normal value—the effect of this regulation can be considered to be a raising or lowering of the net characteristic bodily without any material change in the inclination. Such regulation is always too late by at least the time necessary to produce a change of the indicating device, yet if this amount is small and the demand for current is not very variable such a combination is perfectly satisfactory, and even desirable, on account of the sudden fall of voltage on a short circuit which lessens very materially the shock to all parts of the system.

A second similar combination can be connected in parallel to this first one and the load divided between them—all that is necessary is to have the voltage of the incoming system very nearly equal to that of the bus bar or common point and then to close the switches. Evidently if the voltage of the new dynamo were just right no current could pass in either way, but if it were somewhat too high then a part of the total current would change from the old dynamo to the new one. If, for example, the new dynamo were x volts higher than the old, then the current through it would be of such value as would cause a fall of $\frac{1}{2}x$ on the net characteristic, and the current from the old dynamo would be smaller by the same amount. When the net characteristic is quite drooping, as is always the case with shunt dynamos, there is little or no danger of even overloading an armature when connecting it to the mains, in fact it is common practice in central stations to judge of the voltage of the new dynamo by the looks of its pilot lamp. If the two units (dynamo with its engine) have similar net characteristics, any change of load, sudden or not, will divide equally between them; but if, as usual, the characteristics are not similar this will not be the case, and we shall find that the unit with the steepest characteristic will not take its share of the work if the load increases, and will take more than its share with a decrease of load.

Let the lines A and B in Figure 2 represent the net characteristics of the two units; when the armatures are in parallel and delivering no current, let the voltage be brought to 220 volts, then the two lines are common, as at a. A sudden current of 74 amperes will cause the voltage to drop to 205, and B will deliver 45 and A 29 amperes. If now the load is equalized with 37 amperes in each armature, and the voltage brought up to 220 by the use of the regulating rheostats, the lines A and B are raised to A^1 and B^1 respectively, being common at b; now let the total current be diminished from 74 amperes to 16.5 amperes, a similar construction shows that the voltage will rise to 231.6 volts, and that A will deliver 14.5 amperes, and B 2 amperes.

When two dynamos with net characteristics like these are subject to a rapidly changing load, it is impossible to evenly divide the current, and a balance has to be struck between the limits on the one hand of the dynamo A driving B as a motor—which will, of course, do no especial harm other than to waste energy in heating and sparking—and on the other hand of melting the fuses of dynamo B during an unusually heavy call for power, which might have been safely carried by the fuses if equally divided. It is plain that in this case the combination of the two dynamos is not double the capacity of either one, and the commercial efficiency is considerably lessened by the want of similarity of the net characteristics.

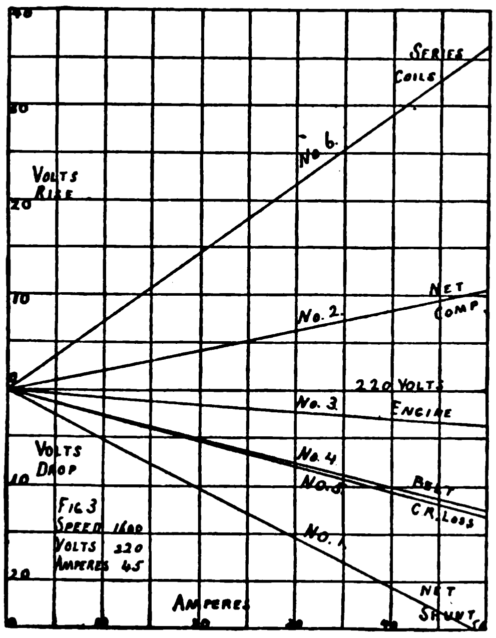


It is very desirable on many accounts to have a dynamo which will automatically maintain an approximately constant potential at the switchboard irrespective of the amount of current flowing. We may add a series winding to the dynamo of just sufficient number of turns to give such a magnetizing effect as will produce a voltage which shall be at all times exactly equal and opposite to the combined effects of the change in engine speed, belt slip, armature reactions, and the drop of voltage due to the resistance of the armatures, lead wires, ammeter, safety devices, and the like, up to the bus bar (Figure 1, Curve 6). The net characteristics will now be made up of the sum of the individual effects, as shown in Figure 1, Curve 2, and the voltage at the switchboard would be constant at all times were it not for the hysteresis of the iron in the magnets, which will very slightly prevent the instantaneous rising and falling of the effect of the series coils, and any change in resistance due to temperature change. The temperature change will be slow, and is corrected by an occasional change of the rheostat in the shunt coil circuit and can be neglected for the present.

---

*Abstract from "Technology Quarterly," Vol. V, No. 4, read March 23, 1893.

Should it be necessary to use a second dynamo of exactly similar design, we cannot proceed as in the case of simple shunt dynamos, for this reason: if the new dynamo is at exactly the same voltage as the mains at the switchboard when connected in parallel, the combination will be unstable, because if for any cause the voltage of either dynamo varies a little, so that the new machine becomes ever so slightly a motor, the effect of the reverse current in its series coil will be to weaken still more the electromotive force, which will allow an increasing current to flow until something burns out.



If, however, there is a third connection made so that the brushes as well as the terminals of the two dynamos are connected, it becomes impossible for this reversal to happen, and the machines will run perfectly under all changes of load.

An examination of the components of the net characteristics (Figure 1, Curve 2,) shows us that if the incoming dynamo be brought up to the voltage of the switchboard and the switch closed, the load will instantly divide between the two dynamos with no disturbance or shock of any kind. Suppose, for instance, that the loaded machine is giving out 40 amperes, we see from the net shunt characteristic (Figure 1, Curve 1) that there is a drop of 20.5 volts, which is made up by the effect of the series coil (Curve 6), giving a terminal potential of 220 volts. When the new machine at 220 volts is switched in parallel we may first consider that one-half the total current of 40 amperes passes through each of the parallel series coils, and from Curve 6 we see that the volts-rise is cut down from 20.5 to 10.2 in the first dynamo and raised from zero to 10.2 in the new one; from Curve 1 we see that for each dynamo this change of 10.2 volts just compensates for a current of 20 amperes through the armature circuits, and that the total load of 40 amperes at 220 volts will be equally divided between the dynamos.

The action of compound constant potential dynamos in parallel is generally misunderstood, and the equalizing connection is credited with a remarkable power of control over the output of such dynamos which it does not and cannot have, as can be seen by watching the dynamos while at work as well as by examination of the makeup of the net characteristic (Figure 1). The common idea is that the equalizer has the property of compelling a lagging dynamo to take its share of the work, and we hear of the wonderful power of control which it has even over dynamos of different types and sizes running under somewhat different conditions. Now the real effect of the equalizer is to put the series coils in parallel, so that the total flow of current from the plant will divide between them inversely as their resistance without any regard as to whether this current comes from one armature alone or is divided among many, and hence it follows that it cannot in any way exercise even the slightest regulating effect on any one dynamo that it does not have over all the rest. The armatures themselves are running in parallel under the usual conditions of ordinary shunt dynamos, and the total current will divide between them under the same laws that would hold if there were no series coils at all and the current were taken from the two main wires to which the brushes are connected.

The net characteristic of the plant is then a falling one as far as the armatures are concerned, to which has been added the automatic regulation of the parallel series coils which act together in proportion to the total flow of current from the station; and if these series coils are all alike in effect, each dynamo will have its voltage altered by an equal amount in proportion to the output of the station, but each armature will not do its share of the work unless all the net falling characteristics are exactly similar.

(*To be continued.*)

South American Indians Instructed.

The Washington *Star* credits Amos J. Thomas with relating the following: "The Bolivian Government," said Mr. Thomas, "recently attempted to establish a telephone line between Lapas and Lake Titicaca, forty-five miles apart. It was torn down and destroyed so frequently by the Indians that the Government was compelled to abandon it. The electric light plant in Lapas was preserved by adopting an ingenious method of overawing the natives. After the plant had been in operation but a few nights it happened that there was an eclipse of the moon. The superstitious Indians believed that the electric light was absorbing or swallowing the moon. They gathered in a large body at one quarter of the town and moved upon the plant to destroy it. It was saved only by the intervention of the troops. The Government the next day selected representative Indians, took them to the power house, shocked them severely, then took them out along the line and shocked them again with the wires, and informed them that the electric light was an evil spirit and that they had better leave it alone. Since then they have had no trouble on that score."

Current Items.

The combined length of the world's telegraph lines is 881,000 miles, or enough to encircle the earth about thirty-three times.

Prof. Bell thinks the time occupied by inventors in working out the problem of aerial navigation by the usual inflated gas-bags and methods of steering them is wasted. He thinks a feasible means of propelling and directing an air ship would be by a kind of trolley system where the rod would hang down from the car to the stretched wire, instead of extending upward. He recommends this idea to inventors.

The selectmen of Brookline, Mass., are considering whether they ought to prohibit the running of an electric carriage in the streets, complaint having been made that it frightened a horse. Mr. Fiske Warren, the owner of the vehicle, cites in defence of such use of it the case of the bicycle, against which similar objections were raised when it first appeared, but are heard no more.

In a paragraph going the rounds it is stated that a New England firm has introduced a new resistance metal in wire, sheet or castings, which is regarded as a very important contribution to this class of material in electrical engineering. The wire resembles ordinary copper wire on the outside, has a pinkish white tinge at the surface of fracture, and is very strong, without losing much ductility. Combined with these favorable mechanical qualities, it is claimed that the wire has the remarkable resistance of thirty-five times that of copper, with a temperature co-efficient of less than one-tenth that of German silver.

One of the most curious displays in the Electrical Building at Chicago is the magic pencil. Large script letters made of different colored electric lamps form the initials of the Western Electrical Company, and behind them is a pole or stick supported by small wires and resembling a huge pencil. This pencil is all the time in motion, its movements being automatically controlled. It starts at the top of the "W," and follows the lines of that letter two down strokes and two up strokes. Then it jumps over to the "E," and finally traces the "Co." Wherever it touches, or appears to touch, it leaves a trail of fire behind it. The first thing it does is to illuminate the topmost lamp of the "W," and then the next lamp below burns brightly, and the third and all the others in turn.

E. T. Evans, a jeweler in Golden, Col., has invented a clock which has electricity for its motive power. The clock in question has neither weight nor spring, but consists only of three wheels, a pendulum, two electric magnets and a battery. The motive power is transmitted to the pendulum and only enough power is required to overcome the lost motion of the pendulum. The two electromagnets are arranged similar to a motor. In starting the pendulum connection is formed on one side and at a certain angle is automatically cut off again, the pendulum swinging back of its own gravity, and as it passes the centre of gravity it makes connection again on the other side, and when it reaches the same angle the current is cut off. The line of contact at each swing of the pendulum is just long enough to give sufficient force to overcome the lost motion. One tooth marks the revolutions every minute and by a very simple device this wheel is connected with the dial wheels. The advantages of this clock are that it never needs winding but will run as long as the battery lasts, which is from twelve to thirty-four months.

Neglect on the part of hotel guests to turn off the gas or electric lights in their rooms when leaving them is an evil for which hotel managers have long been seeking a remedy. A recent invention will probably supply it. A switch has been invented which compels the guest to turn off his light upon leaving his room whether it occurs to him to do so or not. In the modern hotel it is the practice to fit the doors of all guest chambers with "secret" or double bolt locks, one bolt being operated from the inside and the other from the outside, and it is by taking advantage of this arrangement that the new switch is made to carry out its work so successfully. To provide means whereby the occupant of the room may turn the light off from the inside when desired, an auxiliary switch is placed on the inside of the room, in circuit between the controlling door lock and the lamps, in such manner that while the door remains unlocked upon the outside the lamps may be turned on or off at will in the usual manner; but whatever the position of this auxiliary switch may be, as to whether the current is "off" or "on," when the occupant locks his door from the outside upon leaving the room the lights are invariably turned off.

Personal.

Mr. George Walker, of the firm of Claflin & Kimball, Boston, accompanied by his wife, has gone to the World's Fair, and will not be back before July 4.

Mr. Cyrus O. Baker, Jr., of Newark, N. J., whom to know is to esteem, paid a visit to Boston last week. Mr. Baker is entitled to be known as the Ubiquitous Peripatetic, for while he was in Massachusetts only a few days ago, we heard of him only a week or two ago scampering over Europe accompanied by his estimable wife, and ere this he may have reached the Pacific Coast, or be temporarily ensconced in his own office at Newark. Be where he may, he is sure to be among friends.

Mr. W. Burnham, Assistant Manager of the Electric Gas Lighting Company, Boston, has recently suffered from an attack of sickness which necessitated his abrupt return from an unusually successful trip down South.

Mr. Fred Swan, Constructing Electrical Engineer, Boston, has just closed several large contracts for electric lighting plants and apparatus in the State of Maine. Mr. Swan has a very fortunate way of capturing a contract whenever he goes after one.

Mr. Louis Nahm, secretary and treasurer of the American Electrical Manufacturing Company of St. Louis, Mo., was in New York last week. His visit was principally on the business of the company, placing agencies in New York for the lamps they manufacture, which, he said, are meeting with a large demand.

Legal Notes.

The Cowles Electric Smelting and Aluminum Company have had their appeal dismissed by request in the case of the Pittsburg Reduction Company against the former company before the United States Circuit Court of Appeals at Detroit. The patent at issue was the Hall patent, which covers the only commercial method at present used for manufacturing aluminum.

Mrs. Elizabeth Baker has brought suit in Boston against the West End Street Railroad Company for serious bodily injuries which she alleges were received while a passenger on one of its cars that collided with another car through careless management. She claims $20,000 damages and her husband has put in an additional claim of $2,000 for loss of services.

The Court of Common Pleas at Toledo, Ohio, has granted an injunction restraining the Consolidated Street Railway Company, the Metropolitan Street Railway Company and A. E. Lang from proceeding with the construction of the electric railway between Toledo and Maumee. The injunction proceedings were brought by Wm. B. Taylor, who maintains that the building of the road would constitute a breach of contract by the defendants, who before they procured the franchise had made an agreement not to enter into competition with the plaintiff in the construction and operation of a railroad between Toledo and Maumee.

The Erie Telegraph and Telephone Company has filed notice of reduction in the number of directors of that company from twenty-one to twelve. The officers of the company are to consist of a president, secretary and treasurer and twelve directors, all to be chosen by votes of stockholders. But two of the directors are now required to be residents of the State of New York instead of a majority, as was required when the number of the board was increased in 1891.

Chicago Notes.

The first reception at the Ansonia Electric Company's club rooms was given last Thursday. A large number of invited guests were present and included most of the prominent electrical people in the city. The reception was entirely informal, but more enjoyable on that account. A number of vocal and instrumental selections were rendered by the members of the club. Mr. M. M. Wood, of the company, operated a phonograph, affording much pleasure to the guests.

At one of the sessions of the Fire Insurance Congress held in Chicago this week, C. J. H. Woodbury read a paper on "Electricity as a Fire Hazard." Mr. W. J. Jenks also read one on a similar subject.

In an injunction suit brought by one of the residents on the Twenty-second street line against the Chicago City Railway Company to prevent the completion of the electric road, the presiding judge held that the State law limited the rights of the property-owner to his particular mile of the road, and did not extend over the whole line.

The electric fountain in Lincoln Park was started up last Wednesday, and although the Fair was open the fountain proved as attractive as in former years.

Among the visitors noticed in the city last week were James H. Mason, of the Simplex Wire Company of Boston, Mr. C. P. Mackie, of the Electric Selector and Signal Company of New York. Mr. C. B. Fairchild, of the *Street Railway Journal*, is stopping over a week to see the Fair on his trip back from the Coast to New York.

Boston Notes.

The town of Winchester, Mass., entertains a unanimous opinion apparently on the subject of a municipal gas and electric lighting plant. At a recent meeting of citizens there were thirty-seven votes cast in favor and not a single one against accepting the provisions of the Municipal Lighting Act of 1891. A committee was appointed some time ago and will continue its work in the direction indicated by the vote as above. This is the second vote taken on the subject, and it is confidently expected that ere long such a project will be undertaken by the town.

For some time past a change of location for some of its electric car tracks has been contemplated by the Lynn Street Railway Company, which would prove an inconvenience to many of the employees of the General Electric Company engaged in the factories. In consequence, petitions to the company against the proposed change are being got up in the factories and are securing so many signatures, the president, Mr. C. A. Coffin, and nearly all the other officials signing, that the chances are the changes will not be made as the petitioners constitute an entire host of daily patrons over the road.

Notwithstanding the inconvenience caused by a serious fire in the insulated department of the Stanley Electric Manufacturing Company's factory at Pittsfield, Mass., lately, the company, with its ample resources, has been able to keep everything moving, shipping orders daily. The resuscitated department, larger and better equipped than ever, will soon be running full blast again. To enable it to keep up with the extraordinary and increasing demand for its high grade specialties the company is to double its capital, making it $200,000 in future.

A new board of management has been appointed for the Danvers and Beverly Street Railway. This road was operated for a time by storage batteries, the use of which was discontinued and traffic entirely suspended. As the road has recently passed into the hands of the Boston and Lynn Railway Company, there is a prospect of its soon being put into operation again.

The Electric Heat Alarm Company of Boston, whose valuable device is receiving such rapid popularity as a most efficient and reliable piece of apparatus for the prevention of fire, has just issued a handsome little pamphlet describing and illustrating its entire system, which is being called for from everywhere. The representative who is in charge of this company's exhibit at the World's Fair has already closed many excellent contracts for the installation of this device, property-owners alike in the East and West having promptly caught on to its merits and appreciated the solid and useful fact that in buildings where this system is in use insurance premiums are reduced.

The fleet of steamers running between Nantucket Beach and Boston are now equipped with the new Westinghouse incandescent lamp, several hundred of them being used. They give excellent satisfaction.

A party of capitalists from Hartford, Conn., recently visited Milford, Mass., to inspect and investigate the merits of the storage battery system which is there in use with a view to its adoption in Hartford.

General News.

What is Going on in the Electrical World.

Camden, N. J.—The Camden Horse Railroad Company has obtained permission to equip its lines with electricity.

Lockport, N. Y.—The Lock City Electric Railway Company has ordered its new cars from the St. Louis Car Company.

Seattle, Wash.—The city council is considering the supplanting of the incandescent street lighting by a complete arc system.

Columbia, S. C.—The Electric Street Railway Company intend at an early day to extend their new line, forming a belt system.

Richmond, Ind.—The Richmond Light, Heat and Power Company has purchased James M. Starr's entire gas and electric light plant.

Hot Springs, Ark.—The electric cars are now running and give great satisfaction. It is now proposed to build an electric line to the Ouachita River.

Elmira, N. Y.—The electric railroad is to be extended to the village of Horseheads. The Horseheads motor line cars are being converted into electric cars.

St. Louis, Mo.—Charles Stagle has made a general assignment of the Stagle Electric Engineering Company to Gustav F. Decker in trust for the benefit of creditors. Assets, $3,000.

Saratoga, N. Y.—The double-deck cars on the electric road are proving very popular vehicles, and are crowded every trip. Cars run to the Geyser every half hour and to the lake every hour.

Riverside, Cal.—A company has been formed here and a franchise asked for the construction of an electric railway in the principal streets. The scheme is backed by the strongest financial men in the city.

Waterford, N. Y.—The village trustees have closed a contract with the Union Electric Light and Power Company of Lansingburgh and Waterford for twenty electric lights of 1,200 candle power.

Brooklyn, N. Y.—The board of aldermen has granted franchises to the Nassau Electric Railroad Company and to the Kings County Electric Railway Company to run lines in certain specified streets within the city limits.

Toledo, Ohio.—Hon. T. P. Brown proposes to have an electric railway between Toledo and Maumee at an early day if he has to build it himself. He is tired of the legal squabbles in which the project has become involved.

Philadelphia.—Should nothing occur to cause a hitch in the present arrangements, the proposed lease of the Frankford and Southwark Passenger Railway system to the new Electric Traction Company will go into effect July 1.

Hagerstown, Md.—The street commissioners have signed a contract with the Schuyler Electric Light Company of Middletown, Conn., for the lighting of the streets, avenues and highways of Hagerstown for five years from July 1.

Salida, Col.—The local Edison Electric Light Company have decided to use water instead of steam power, and are having a huge ditch made to bring the water to their works, a mile from the source. The stream will supply about 500 H. P.

New Orleans.—The Electric Traction Company, Limited, has come to an agreement with the Crescent City Railroad Company under which the Traction Company will make electric systems of the Crescent City and the Judah Hart lines.

Paterson, N. J.—An agreement having been reached by the Newark and Paterson Electric Railway Company and the Franklin Township Committee, the electric line between Paterson and Newark will be completed as soon as possible.

Jersey City, N. J.—The Passaic Elevated Transit Company have negotiated a loan of $2,000,000 and will construct a double-tracked elevated railway line from West Side avenue, Jersey City, to Broad street, Newark. Either electric or steam power may be used.

Rome, N. Y.—The present contract with the Rome Gas Light Company for lighting the city with electricity will expire next fall, and a special committee has been appointed by the mayor to consider whether it would be advisable for the city to purchase a plant and do its own lighting.

Queretaro, Mex.—Governor Casio, who has lately visited a number of cities in the United States, investigated the subject of municipal lighting by electricity while there, with a view to establishing an electric lighting plant at Queretaro, the capital of the State, in which he has been a ruling power for years.

Manitou, Col.—A franchise to construct an electric railway on Ruxton and Manitou avenues has been granted to M. A. Leddy. The road will cost about $50,000, and $200,000 additional will be applied to the erection of a mammoth casino near the Iron Springs which is expected to increase travel on the road by its attractive features.

Americus, Ga.—The Thomson-Houston Company, owners of the defunct street railway in this city, are making preparations to remove the rails, wires and other appurtenances from the streets under a recent order of the city council requirits removal within thirty days. The road is five miles long and cost somewhere between $25,000 and $30,000.

Hartford, Conn.—E. P. Usher, the general manager of the Milford and Hopedale Electric Company, says he hopes and expects to be able to reach an agreement with the Hartford and Wethersfield Horse Railroad Company by which the Hopedale storage battery system may be put in actual operation here; probably on the Parkville line.

Kansas City, Mo.—The Interstate Water and Electric Power Company expect to begin work in a short time in building a dam across the Kaw River near Muncie and locating a big electric power plant there. From this plant the projectors propose to furnish electric power to operate mills, street railways and to furnish the two Kansas Citys with cheap lights.

Cleveland, Ohio.—A company, to be known as the Eastern Electrical Equipment Company, has been organized here for the purpose of promoting a new electric car which is constructed with a view to economy in room and protection to the motorman, who is to have an elevated compartment to himself, where he can give undivided attention to his duties without any obstruction or interference from passengers.

San Diego, Cal.—The Electric Railway Company, it is said, propose to lay out a park in the suburbs at an expense of $75,000. The park is to be modeled after a famous park in Honolulu, and a landscape gardener is now there copying the plans. These are to be brought here and are to be closely followed. The park will contain about 160 acres, and will be used as picnic grounds and as a source of attraction to induce people to travel over the electric railway.

Newark, N. J.—The plant, leasehold interests, etc., of the defunct Schuyler Electric Light and Power Company have been purchased by the Central Power Company, a Newark concern of some years' standing. It having been stated that the Consolidated Traction Company and the Newark Electric Light and Power Company were interested in the above purchase, representatives of those companies deny that they had any part or interest in the transaction.

Miamisburg, Ohio.—The Miamisburg Electric Company has begun here what promises to expand into an extensive business. The company is capitalized at $100,000, and will manufacture the Burnley cartridge batteries, the Imperial dry batteries, commutator segments, commutator brushes, copper brushes and various attachments for dynamos and electric machines in which copper is used. The officers of the company are: T. V. Lyons, president; W. A. Mays, vice-president; Wm. Gamble, treasurer; D. H. Allen, secretary.

Buffalo, N. Y.—Dr. Hill, city chemist, recently tested the lights furnished the city by the General Electric Company, and found them of much less C. P. than the contract called for. The electric company then had a test made in a darkened room, by Profs. Whitthaus, Vanderbergh and Randall, who found the light furnished even stronger than that specified in the contract (2,000 C. P.) Dr. Hill's tests were made in the street. He still believes his tests the more accurate.

New York.—Several of the new trolley cars of the Westinghouse system have been received at the shops of the Union Railway Company at 170th street and Third avenue. They differ from the present cars in that the reserve battery, which is intended for use in cases of emergency, is located in an iron cylinder in front of the dashboard, instead of under the car.—An electric drill, the invention of Wesley Webber, of Pittsburg, Pa., is to be tested in a day or two in boring an artesian well 1,500 feet deep at the power-house of the Broadway Railway.

Elizabeth, N. J.—The Suburban Electric Light Company's plant, which furnished light to Elizabeth and its suburbs, was destroyed by fire on the night of the 19th inst. The loss is estimated at over $100,000. The building destroyed contained a new triple-compound 600 horse-power Corliss engine, two 300 horse-power engines, two dynamos, each of 500 volts, six alternating and two 220 volt machines, two arc power, two small high speed engines and a lot of other valuable machinery. Most of the machinery to operate the Elizabeth and Plainfield Electric Railway was stored in the building.—The Elizabeth and Plainfield Electric Railway Company, being unwilling to assume the burdens that the city council were inclined to impose, have withdrawn their application for a franchise for the projected road.

"Queen" Apparatus at the World's Fair.

The standard electrical instruments exhibited by this company are attracting increased attention each day, and prove of considerable interest to all who appreciate strictly high class workmanship.

The Armour Institute of Chicago is equipping an electrical laboratory in good style, and has already reserved some $3,000 worth of the instruments exhibited by Queen & Company. These are to be delivered in November after the Exposition has closed. The manufacturers consider this as a happy compliment to their product, as Mr. Armour spares no money in making his equipment the best in the country.

The De Mott Electric Motors.

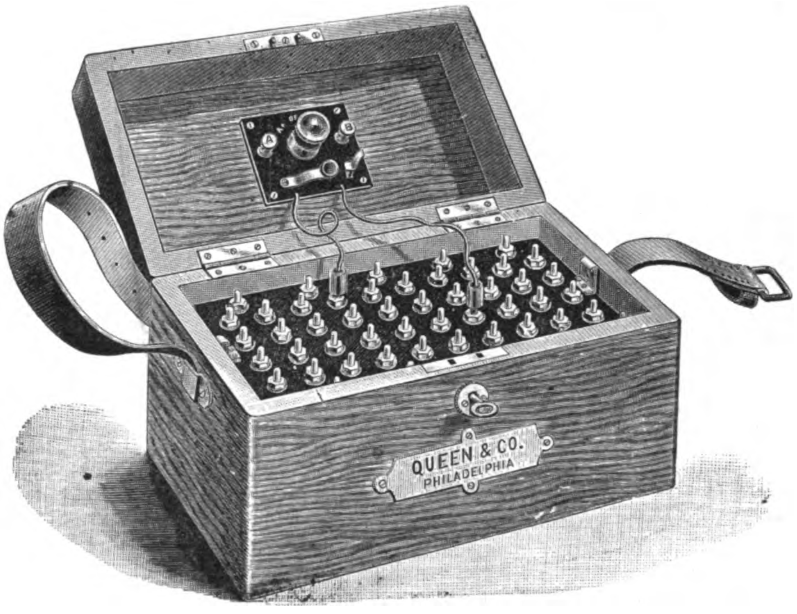
Messrs. J. Jones & Son, 39 Vesey street, New York, report a very satisfactory demand for the De Mott Motors and De Mott Improved Bluestone Battery, for which they are agents. The motors embody several improvements not found in other motors on the market, and no expense has been spared by the manufacturers to enable them to give to the trade an article which they say is an "ideal in miniature motors." They claim for it "symmetry in appearance, no dead centre, practically noiseless while in operation, and more work with the same amount of current than any other motor." The motors are designed to operate mechanical toys, model machinery, turn tables, toy launches, music boxes and miniature machinery of all kinds and for ventilation purposes, and they can be run on the ordinary bluestone battery, or with the De Mott Improved Bluestone Battery. The prices range from $4 to $15 for the motor, and the improved battery is sold at $1.75 to $2.00 according to size; fans from 50 cts. to $1.50.

The "Aluminum-Iodine" Portable Testing Battery.

The Testing Battery illustrated herewith is a new form that has been thoroughly developed in the experimental department of Queen & Company, Incorporated, Philadelphia, and is now placed on the market by this company with expectation of a large demand.

In chemical composition the "Aluminum-Iodine" cell is quite different from anything heretofore known, and possesses important features the most essential of which is high electromotive force. Each one develops a voltage of 1 4-10 volts, which is fully 50 per cent. more than the output of an ordinary "Chloride of Silver" cell. The effect, as will be seen, is that 50 aluminum silver cells have the same efficiency as 75 of the other type, so that great economy in first cost results.

The cells are prepared with great care, and those used in the laboratory of Queen & Company for months past have shown remarkable constancy and long life. There is no danger of explosion or leakage, and local action is practically eliminated, so that when not in use there is no injurious waste.



The "Aluminum-Iodine" Portable Testing Battery.

The cells are mounted in handsome polished mahogany cases in sets of 50, more or less as desired. A battery of 50 cells gives 70 volts E. M. F., which is quite sufficient for all ordinary work. Electrical engineers in testing the insulation of submarine or underground cables often require 200 or 300 volts to secure proper sensibility in results, and a battery of as many cells can readily be prepared if desired.

The "Acme" Portable Testing Set, also manufactured by Queen & Company, contains twelve "Aluminum-Iodine" cells, which they propose to use entirely in place of the regular "Chloride of Silver" form.

The makers are prepared to meet a large demand for this new specialty, and interested parties should write them for a copy of descriptive circular No. 445.

The Carpenter Enamel Rheostat Company.

The catalogue of the Carpenter Enamel Rheostat Company, of Bridgeport, Conn., issued the present month, contains a number of illustrations showing various forms of rheostats, theatre dimmers, arc lamp resistances, feeder equalizers and regulators for fan motors, with brief but explicit descriptions of the machines and appliances manufactured by the company, also tables giving sizes, capacities and prices of the various articles. A large number of letters from electrical companies, theatre managers and others, attesting the satisfaction the rheostats, etc., have given to all who have dealt in or used them, are appended to the catalogue, and the general tenor of these is indicative of a very high efficiency in the machines and their thorough adaptability to the services required of them. The Catalogue can be obtained by applying to Chas. D. Shain, general selling agent, 136 Liberty street, New York, or to the company, as above.

The Joseph Dixon Company's World's Fair Exhibit.

The Joseph Dixon Crucible Company is the only concern in the world which manufactures every article of which graphite is a component part. With the invention by Joseph Dixon in 1827 of the plumbago crucible, the crucible business was revolutionized. At that date began also the manufacture of Dixon's stove polish, foundry facings, and the development of an industry now grown to enormous proportions and fittingly represented by the Joseph Dixon Crucible Company.

This company has two exhibits at the Fair. One is of Dixon's American Graphite Pencils, in the northeast gallery of the Manufactures Building, and the other, covering all the other articles manufactured by them, in the northeast gallery of the Mines and Mining Building. The Pencil exhibit occupies a space 10 by 14 feet. In the centre of this space stands a low mahogany table surmounted by a pyramid of velvet which is covered with pencils arranged in graceful and beautiful designs by an artist employed specially for that purpose. Over this pyramid stands a rosewood and plate-glass case. Two ornamental facades of turned and carved mahogany front the space, which is separated from neighboring spaces by means of Japanese bead curtains suspended from carved grilles.

The space is lighted at night by means of two gilt electroliers of six 16 candle power lights each.

The company's exhibit of general and special graphite products in the Mines and Mining Building occupies a space 25 by 28 feet. A very handsome cherry facade fronts the space while the sides are hung with tastefully arranged portieres. Crucibles, retorts, ladles, stopper-heads and nozzles, graphite boxes, phosphorus chargers, resistance rods and devices, incandescent filament forms and other special goods made of graphite are shown in upright cabinets. In another case is shown the development of an electrotype plate, in which process the use of graphite is an essential. In still another case are shown over fifty varieties of graphite, for as many different uses and under as many different names, such as graphite for lubricating, stove polish, foundry facings; for green, dry or loam castings; core wash, ingot mold wash, shot and power glazing; for electrotypers, gilders' use, hatters' use; rubber packings, piano and organ actions; "pot-leading" yachts; for crucibles, lead pencils, paint pigment, lubricants, etc., etc.

There are also shown samples of graphite from all the principal sources from which that article is obtained. One very fine sample from the Island of Ceylon weighs nearly 300 pounds. Comfortable chairs, with writing desks and stationery for the free use of those who may desire it, give to the exhibit an air of genial comfort and ease.

The Dixon Company were the first to complete their exhibit and their promptness brought forth the following letter from the Chief of the Department:

World's Columbian Commission.
Office of the Director-General of the Exposition.
Chicago, Ill., U. S. A., May 20, 1893.

MR. JOHN A. WALKER, Vice-President,
Joseph Dixon Crucible Co., Jersey City, N. J.

Dear Sir: I am in receipt of your esteemed favor of the 17th instant, and in reply beg to state that the Department is much pleased with the promptness with which your exhibit in this building was installed and completed through the supervision of your able assistant, Mr. McNaughton, and also to heartily congratulate you on making a display which is in every particular attractive and dignified, and which fully illustrates in an interesting and instructive manner the graphite industry.

Yours very respectfully,
F. J. V. SKIFF, Chief.

The Page Belting Company.

This well-known company, which is said to have the largest and best equipped belt factory in this country, if not in the world, has a very extensive exhibit at the World's Fair, where it has demonstrated the possibility of manufacturing enormous belts to run tandem at tremendous speed in the successful operation of the two belts on the powerful Allis engine at the Fair, one 72-inch and the other 71-inch. These belts are run at 5,600 feet per minute and each transmits 4,000 H. P.; they were put in place and started at once at full capacity and have run perfectly without being touched since they were set to work. The Anniversary Souvenir which the company has had printed to commemorate the twenty-fifth year of its existence is a neatly printed work, containing a history of the company from its origin, a description of the belting works and their productions, and numerous illustrations, among which are pictures of the building in which the Page brothers began business and of their present extensive factories, a panorama of the World's Fair, the managers' dwellings in New York, Boston and Chicago, the company's pavilion in Machinery Hall at the Chicago Exposition, its exhibit in the Electrical Building, the processes by which the largest belts in use are manufactured, the large tandem belts running on the Allis engine at the World's Fair, interior views of the company's stores, etc. The souvenir is copyrighted.

COMMERCIAL PARAGRAPHS.

We understand that business is very brisk with the New York branch of the Mather Electric Company, and that they have recently added to their force the services of Mr. Henry M. Stiles (formerly with the Thomson-Houston Company) as electrical engineer, and Mr. Harry W. Colby (formerly with the General Electric Company) as general agent for the sale of power apparatus and lighting plants. Mr. A. E. Bowers has entered the service of Messrs. Claflin & Kimball, sole agents of the new "Novak" lamp, and can be found at the office of the company, 97 Nassau street. He will have entire charge of that line of the business.

The company, as we have said, are enjoying a brisk run of business. Last week they closed a contract with the Lynchburg (Va.) Electric Company for a 100 H. P. generator, and several contracts for small motors.

The W. S. Hill Electric Company, 133 Oliver street, Boston, have published a convenient little hand-book containing illustrations and price lists of the various switches, rheostats, switchboards, etc., manufactured by the company, all of which are in popular demand and bear a high reputation. The company also furnish motors and generators for all purposes, made under their own patents, and will be pleased to answer all inquiries.

The Wirt regulating switch used for dimming incandescent lights, particularly for use in bed rooms and nurseries, seems to be winning popular favor, as two different papers have written to the Ansonia Electric Company, the manufacturers, for electrotypes for illustration.

The Ansonia Electric Company report the sale of Wirt Brushes to be on a steady increase, and heavy sales in Stanley Moisture-Proof Transformers and Habirshaw Wire, as well as Crocker-Wheeler Motors, especially of the fan type.

A. M. Morse & Company, contracting engineers, St. Louis, and the Southwestern representatives of the Buckeye Engine Company, report several important recent contracts for Buckeye Engines. Prominent among them are a 500 horse power plant for the electric lighting station of the new St. Louis Union Depot, consisting of three tandem compound non-condensing engines, direct coupled to Siemens & Halske slow speed multipolar generators. Also an 800 horse power plant consisting of four medium speed engines for the Alton Electric Street Railway, Alton, Ill.

INCORPORATIONS.

A charter has been granted to the York and Dallastown Electric Railway Company of York, Pa. Capital stock, $60,000.

The Kings County Electric Railroad Company, Brooklyn, N. Y.—to build and operate an electric railway line in Brooklyn. Capital stock, $500,000.

The Coney Island, Fort Hamilton and Brooklyn Railroad Company, Brooklyn, N. Y.—to build an electric double-track freight and passenger road from 89th street, Brooklyn, to Coney Island. Capital stock, $500,000. Promoter, P. H. Flynn.

The Kenosha Electric Light Company, Kenosha, Wis.—to establish an electric light plant. Capital stock, $15,000. Promoters: E. G. Hazelton, L. Bain and U. J. Lewis.

The Electric Shorthand Company of Chicago, Ill. Capital stock, $10,000. Incorporators: David F. Haymes, M. E. Haymes and M. W. Kenney.

The Maine Electrical Construction Company, Fairfield, Me.—to construct and equip electrical plants. Capital stock, $10,000. Promoters: Chas. H. Maxfield, Frank Vickery, B. F. Maxfield, John R. Donnelly, all of Fairfield, Maine.

The Columbian Electrical Company, St. Joseph, Mo.—to do a general electrical business. Capital stock, $2,000. Promoters: Geo. S. Rough, Chas. E. Roehl, Frank C. Barrington, all of St. Joseph, Mo.

The O. O. Electric Company has been organized at Saco, Me., for the purpose of carrying on a general electrical and mechanical manufacturing business. Capital stock, $10,000. President, J. B. Duff; treasurer, H. B. Bennett.

The Waco (Tex.) Electric Light and Street Railway Company has increased its capital stock from $250,000 to $300,000. The company may put in an arc plant shortly.

The Painter and Morrison Company, Baltimore, Md.—to deal in electric lamps, switch sockets, electric switches and electric drop lights. Capital stock, $5,000. Promoters: J. F. Morrison, G. E. Painter, D. F. Pennington, S. Nordlinger, E. D. Crock, H. Samuel, G. A. Miller, E. O. Quigley.

The Trenton Electric Construction Company, Trenton, N. J.—to manufacture, install, construct, operate and sell every kind of electrical apparatus. Capital stock, $25,000. Promoters: Geo. F. Applegate, J. P. Toman, Carl F. Adam, Anton Adam, Paul Lupke, all of Trenton, N. J.

The Cummings and Engleman Conduit Company, Detroit, Mich.—to manufacture, sell and lay conduits for electrical purposes, also construction of electric railway and power plants. Capital stock, $300,000. Promoters: Jas. F. Cummings, Eugene M. Engleman and James H. Land.

The Richmond Light, Heat and Power Company, Richmond, Ind.—to manufacture and sell gas and electricity, and gas and electrical machinery for light, heat and power purposes. Capital stock, $300,000. Promoters: Jas. D. Platt, Joe E. Lewes, Jas. C. Reber and Archibald Stuart.

The North Chicago Electric Railway Company, Chicago, Ill.—to construct, lease, buy or acquire horse, dummy and street railroads in Chicago and adjoining territory in Cook County, Ill. Promoters: Chas. H. Gurney, Jno. E. Burke and Alex. M. Savage.

The Young-Moskowitz Railway Car Electric Lighting Company, Newark, N. J.—to manufacture apparatus and light railroad cars by electricity. Capital stock, $1,000,000. Incorporators: Charles A. Sterling, F. C. O'Reilly, Leon D. Adler, James F. Connelly, Joseph Lowenberg, Dr. H. C. H. Herold, Samuel Young, E. B. Gaddis, Morris Moskowitz and B. W Hopper.

The Eagle Electric Manufacturing Company, of South Superior, Wis. Capital stock, $4,000. Incorporators: A. Striemer, E. A. Noble and O. J. Graham.

The Washington Electric Company, Chicago—to manufacture and deal in electrical and mechanical appliances. Capital stock, $40,000. Promoters: Victor W. Johnson, Olaf R. Iverson, Wm. L. Maddock.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JUNE 20, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

499,805. Electric-Railway Grade Crossing Device. Joseph B. Stewart, Haverstraw, assignor of one-third to Joseph P. Bradfield, Syracuse, N. Y. Filed Aug. 26, 1892.

499,871. Trussed Trolley-Board for Electric Cars. Henry Cochran, Chester, Pa. Filed Jan. 16, 1893.

499,943. Trolley-Wire Hanger. Lorenz Spillman, Columbus, Ohio. Filed Jan. 21, 1893.

500,065. Closed Conduit for Electric-Railways. John C. Henry, New York, N. Y. Filed Sept. 8, 1890.

500,066. Electric Locomotive. John C. Henry, New York, N. Y. Filed Oct. 18, 1890.

500,067. Electric Locomotive. John C. Henry, New York, N. Y. Filed Dec. 16, 1891.

500,068. Electric-Railway System. John C. Henry, New York, N. Y. Filed April 29, 1892.

500,070. Electric-Railway Trolley. John C. Henry, Westfield, N. J. Original application filed Sept. 3, 1890. Divided and this application filed Feb. 1, 1893.

500,104. Electric-Railway System. Charles J. Reed, Orange, N. J., assignor of one-third to Gustav Stahl, Philadelphia, Pa. Filed June 27, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

499,908. Stand for Electric Lamps. Josef Cathrein, Innspruck, Austria-Hungary. Filed Feb. 15, 1893.

499,916. Mode of and Means for Renewing the Filaments of Electric Incandescent Lamps. Gustav A. Frei, Springfield, Mass. Filed Nov. 14, 1892.

500,026. Electric-Lighting System. Charles L. Morey, Centralia, Ill. Filed Feb. 11, 1893.

500,053. Incandescent Electric Lamp. Edward E. Cary, Boston, Mass. Filed April 7, 1893.

500,075. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed April 1, 1893.

500,076. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed April 3, 1893.

500,077. Incandescent Electric Lamp. William E. Nickerson, Cambridge, and Edward E. Cary, Boston, Mass. Filed April 5, 1893.

500,078. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed April 5, 1893.

500,079. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed April 7, 1893.

DYNAMOS, MOTORS, ETC.

499,769. Regulator for Electric Motors. George H. Whittingham, Baltimore, Md. Filed March 24, 1892.

499,780. Means for Storing and Supplying Electrical Energy by Natural Force. Frederick G. Corning, New York, N. Y. Filed Nov. 14, 1892.

BATTERIES.

499,848. Secondary Battery. Fred O. Norton, Oroville, Cal. Filed May 26, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

499,748. Telephone Exchange. Alfred E. McClaren, Joplin, Mo. Filed June 13, 1892.

499,811. Telegraphy. Pierson J. Wicks, Brooklyn, assignor to the Western Union Telegraph Company, New York, N. Y. Filed March 3, 1893.

SIGNALS AND SIGNALING APPARATUS.

500,041. Electric Signal. George W. Swartz, Florence, Ala. Filed Oct. 31, 1892.

MISCELLANEOUS.

499,726. Productions of Alloys by Electro-Deposition. Charles R. Fletcher, Boston Mass. Filed Feb. 18, 1892.

499,737. Secondary Electric Clock. Richard S. Howland, Providence, R. I. Filed Jan. 4, 1893.

499,852. Electric Converter. Gustav Pfannkuche, Exeter, N. H., and Alfred Pfannkuche, Cleveland, Ohio, assignors to the Brush Electric Company, Cleveland, Ohio. Filed May 13, 1887.

499,864. Electric-Alarm Money Drawer. William J. Walker and Alexander L Bedford, St. Louis, Mo. Filed Feb. 17, 1893.

499,879. Phonograph. Thomas A. Edison, Llewellyn Park, N. J., assignor to the Edison Phonograph Company of New Jersey. Filed July 30, 1888.

499,921. Electric Stop Mechanism for Knitting-Machines. Frank Hammond, Paris, Canada, assignor of one-third to John Penman, same place. Filed Jan. 9, 1893.

499,930. Electric Cut-Out. Otto F. Persson, Lynn, assignor of one-half to Hjalmar C. Schelin, Boston, Mass. Filed May 1, 1893.

499,964. Electric-Bath Metal-Heating Apparatus and Process. George D. Burton, Boston, and Edwin E. Angell, Somerville, Mass., assignors to the Electrical Forging Company of Maine. Filed Dec. 31, 1892.

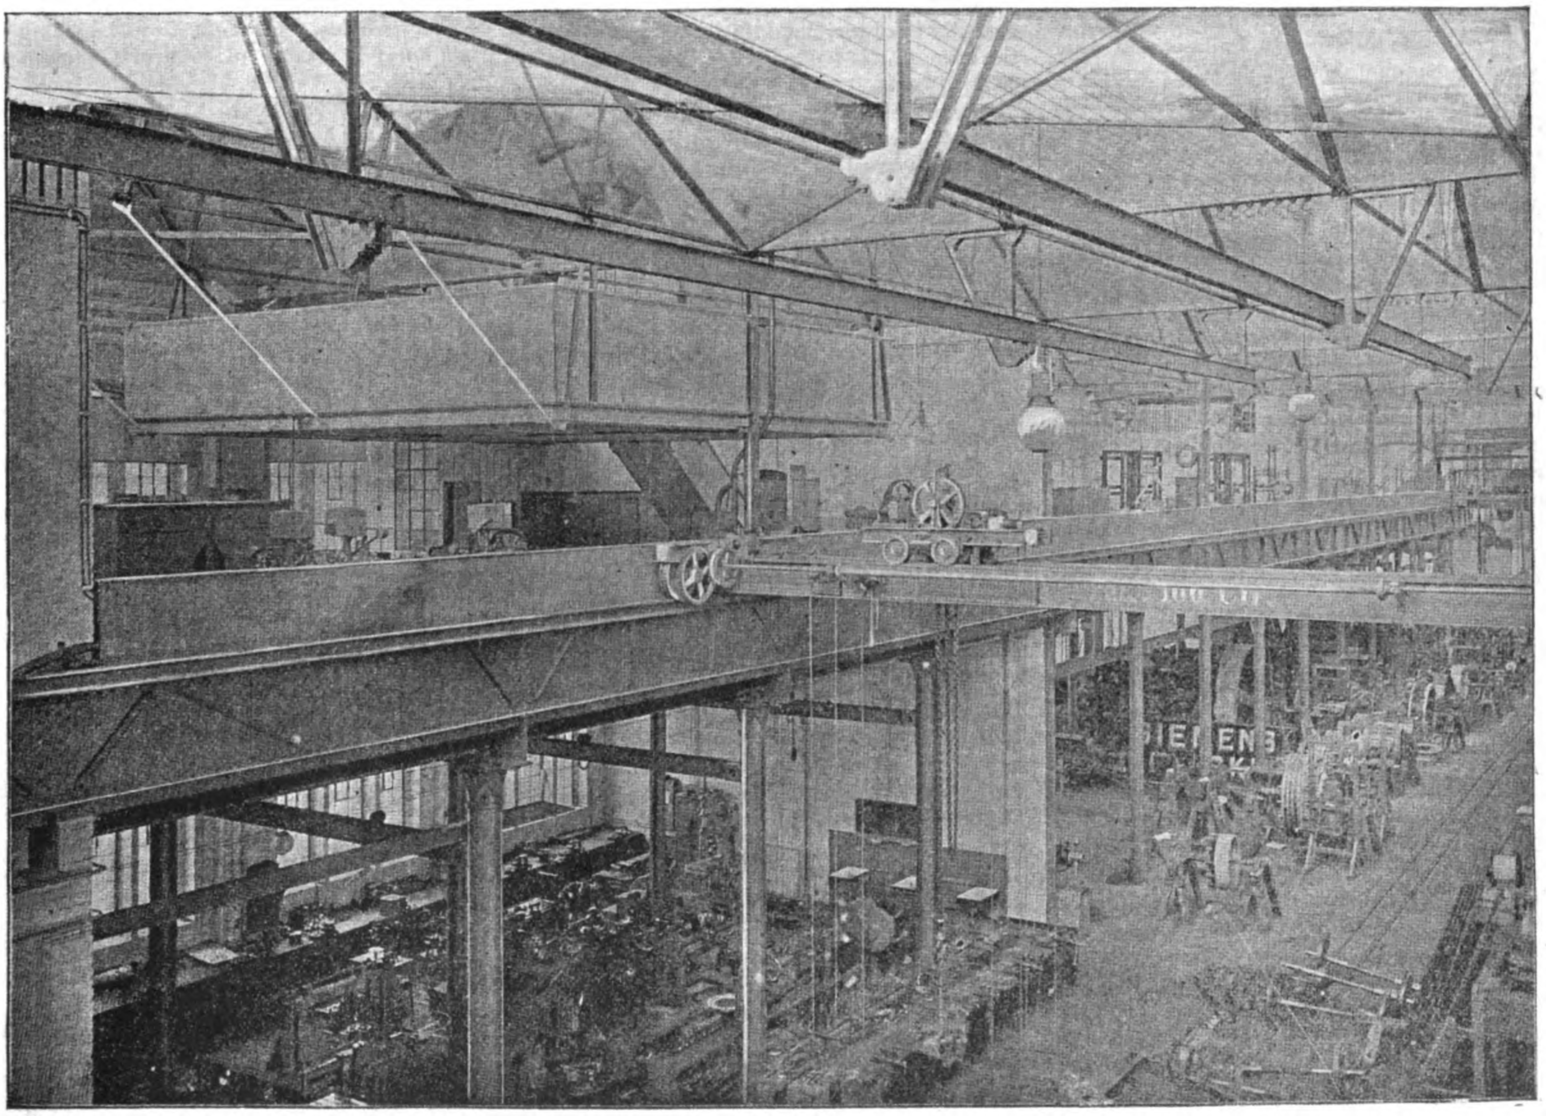
ELECTRICITY.

VOL. IV. NEW YORK. JULY 5, 1893. CHICAGO. No. 25



SIEMENS & HALSKE'S CHARLOTTENBURG WORKS. (SEE PAGE 338.)

Electrical Shop Equipments.

The subject of separate motors for machine tools which are directly connected to the moving parts of a machine is coming forward as an important element in manufacturing establishments, and although a comparatively recent innovation it promises to play an important part in the economy of operation of the workshop.

Some interesting data on this subject was given in a paper read before the *Electrotechnische Verein* by Mr. Richter, chief engineer of Siemens & Halske's works.

The subject was considered under three different heads:

1. The factory is driven by an electromotor in the same way as by a steam engine, a turbine, or other motor; in other words, the electromotor takes the place of the steam engine, etc.
2. The factory is divided into several groups, each of which is driven by an electromotor; so-called group working.
3. Each work machine receives its own electromotor; so-called separate or single working.

As an example of the first method may be mentioned a spinning mill at St. Blasien, in the Black Forest, which is driven by turbines, and where the water that has driven these turbines is utilized again, about one kilometre below the factory, by another turbine installation, and the 200 horse power obtained there is transformed into electrical energy and transmitted back to the factory to yield 150 horse power to the main shaft.

The same mode of working also occurs in factories consisting of separate buildings at some distance from one another, and where electromotor working, compared with steam working, will be found economical. Mr. Richter mentions an example of this from his own practice.

It was a question of replacing in a sugar refinery a 35 horse power steam engine, placed in a distant building, by an electromotor to be supplied with current from an electric central station working at a high efficiency, while the steam-engine received its steam from the same boiler plant.

The steam dynamos of the central station consume 7 kg. of steam per effective horse power per hour. At an efficiency of only 90 per cent. for the steam dynamos, of 95 per cent. for the line, and of 90 per cent. for the 35 horse power electromotor, we find a total efficiency of 77 per cent., which means that in the central station 9·1 kg. of steam per hour would have to be expended for each effective horse power produced in the distant building.

The steam consumption of the 35 horse power steam engine amounted at least to 17 kg. per horse power hour, and was, in fact inclusive of the loss in the long pipes, 20 kg. A saving of 54 per cent. was thus effected by electric working.

As an example of group working Messrs. Siemens & Halske's Charlottenburg factory may be mentioned. The arc lamp factory, opened in 1890, is provided in each of its six rooms with an electromotor driving a short transmission shaft with two safety couplings. From these two electric couplings two shafts running the length of the room are driven, and from these latter, by means of an intermediate gearing fastened to the ceiling, are driven the tool machines. Thus every room is independent of the others, and is besides by the safety coupling divided into two parts independent of each other, so that if from any reason the work has to be interrupted in one place this derangement need only extend to half the room.

There is yet another advantage attached to this arrangement, and that is that all the transmissions from one room to another are avoided, and consequently also those dangers caused by the openings in the ceilings made for belt transmission, and which have often contributed to the spreading of fire. And, further, the main transmissions, which are a source of great loss of power, are avoided by group working.

After the favorable results obtained by group working, the 100 horse power steam engine installed in the oldest portion of the Charlottenburg works has been put out of operation, the various sections of the transmission have been divided into five groups, and each group has been driven by an electromotor of proper size. The working current was supplied from the electric station, which is fitted with a highly efficient boiler and machinery plant.

In addition to the saving of energy by suppression of the main transmissions, this arrangement has also the advantage that for night work of individual tool machines the whole transmission need not be run, but only a special portion of a certain section.

Mr. Hartmann, of the firm of Hartmann & Braun, Bockenheim, who has made similar tests, found that the losses of energy caused by transmissions were by no means so small as is generally supposed. He ascertained that a triple transmission had an efficiency of from 13.7 to 66 per cent., or a mean of 47 per cent., and a double transmission of from 52.1 to 71 per cent., or a mean efficiency of 64 per cent., according to the size and extent of the transmission. The numerous investigations made by Messrs. Siemens and Halske have given similar results. In triple transmissions an efficiency of less than 50 per cent. has repeatedly been found, and in double transmissions the mean of many observations was found to be 65.6 per cent. The results, however, are entirely different in installations where all the machines are not always in operation, a condition which obtains in most of the factories. In several of the workshops of the Charlottenburg works Mr. Richter has for some time kept a careful record of the actual working hours of the tool machines, and has found that these hours amounted to from 47 to 74 per cent., or a mean of 62 per cent. of the whole working time. The mean efficiency of a triple transmission is hereby reduced to 29 per cent., and that of a triple transmission to 40 per cent.

Now, as regards electric group working, it will be clear that by arranging the tool machines in smaller groups, so that the intervals of work always affect a whole group, this running without a load can be avoided. If, further, the installation is made in such a way that a double transmission can be dispensed with, a considerable advantage, from a commercial point of view, will be obtained by electric working.

Assuming 90 per cent. to be the efficiency of the generator, 95 per cent. that of the line, and 85 per cent. that of the electromotor (all these values are taken rather low), we get a total efficiency of 72½ per cent., as against 64 per cent. or 40 per cent. for double transmission.

To distribute the machines in such a way that all the machines of the same group are always simultaneously at work will be found difficult because it must naturally tend to making the groups smaller and thus lead to single motor working. At first sight it may seem strange to provide each tool machine with its own electromotor. The objections against such an arrangement are that it renders the installation too expensive, and that on account of the low efficiency of small motors such a system is not economical. Both these contentions are true to a certain extent. As regards, first of all, the prime cost, Mr. Richter has made a large number of calculations, and has found, for instance, that in one of the rooms of the arc lamp factory, where, as has been mentioned, group working has been adopted, and which contains 42 tool machines driven by a 25 horse power electromotor, the prime cost would only have been 13 per cent. dearer if, instead of the one electromotor with transmissions and belts, 42 electromotors with their accessories had been employed. In another room containing 29 tool machines, driven by an 8 horse power electromotor, the result would have been even more favorable, so that a mean of 10 per cent. may be assumed. It must, however, be pointed out that this 10 per cent. only refers to the prime cost of the motor installation and not to the cost of the tool machines, so that on comparing the total cost of single working with that of group working of the whole installation the additional expenditure would hardly amount to more than 3 or 4 per cent.

Now, as regards the efficiency, we will at once assume the most unfavorable case. An electromotor of ¼ horse power, the smallest to be used for similar purposes, has an efficiency of 70 per cent.; taking the efficiency of the line at 90 per cent., and that of the generator also at 90 per cent., we get a total efficiency of 57 per cent. Supposing, further, the tool machine to be joined to the motor by an intermediary piece absorbing 10 per cent., we get a total efficiency of over 51 per cent. Comparing this with the 40 per cent. efficiency of a double transmission it will be seen that the result is not nearly so bad as might be expected. It is clear that in a factory where the working hours of the tool machines exceed 62 per cent. of the total working time the result would be more unfavorable, but even in this case the efficiency would only be inferior to a double transmission if the above percentage amounted to 80 per cent. In basing our calculation, not on the smallest, but on motors of average size, for instance of one horse power, we find that the above figure of 57 rises to 61 per cent., and that of 51 to 55 per cent.; assuming the working hours of the tool machines to be 81 per cent. of the total working time, the efficiency of single motor working will be found equal to that of a double transmission. Compared with group working which, on account of the larger motors employed, has a higher efficiency than single motor working in proportion of 9.8, we may say that single working with motors of one horse power mean capacity, assuming the working hours of the tool machine to be 75 per cent of the total working time, gives the same efficiency as group working where the whole of the machines of one group are either working or standing still at the same time.

Single motor working presents special advantages which will, in many cases, compensate for the higher prime cost. In the first place, by combining the motor with the tool machine, the belts, which so greatly obstruct the light, are dispensed with; the appearance of the room and the light are improved and the existing space can be utilized for the erection of gallerie . The Frontispiece shows such a gallery on which there is working room for twenty-five men. The building, not having to support transmissions, can be of lighter construction; the tool machines can easily be shifted for certain work, requiring only an alteration of the electric wires; the cost of maintenance is diminished by the absence of long belts, and finally a complete independence of the various tool machines is obtained, so that for working after hours or during the dinner hour any one of the machines can be operated without being obliged to run a transmission consuming much power.

Another Non-Infringing Lamp.

Four patents have been issued to W. E. Nickerson and one to Edward Cary, both of Boston, on an incandescent lamp which is outside of the Edison patent. The lamps will be on the market within a few weeks.

The Action of Compound Dynamos When Run in Parallel.—II.

BY WILLIAM L. PUFFER, S. B.*

In a plant of such dynamos each driven by its own engine it is most likely that the net falling characteristics of the armatures will not all have the same steepness, and consequently a fluctuating load will not be shared equally by the dynamos; but it is possible to so arrange things that the series coils do not all act equally on the armatures, and if the resistances of the series coils are slightly changed by the addition of a little German silver or copper ribbon so that the total flow of current divides between the different series coils in such a proportion that the individual net armature characteristics are raised by just the right amount, we again have a plant in which a fluctuating load will divide equally among the different dynamos. The same effect may be produced by the addition of a small resistance in the armature circuit of any dynamo which takes more than its share of an increase of load. A number of machines so adjusted will run together perfectly, and there will be no change of voltage or any difficulty experienced in cutting in or out by the use of the ordinary two or three pole switch; the only precaution to be observed is to have the voltage of a new machine nearly that of the bus bars, for then, when the series coil is put in parallel with all other series coils, it will be traversed by such a part of the total flow of current as will be sufficient to raise the voltage of the armature enough to enable it to deliver its share of the total output.

If a dynamo is to be cut out it will not do to reduce its load first by the use of the resistance in the field circuit, because by this process its load is transferred to the other dynamo armatures and the station voltage will consequently fall somewhat, because the series coils are not proportionally increased. This fall of voltage may or may not be permissible, and is avoided if the switch is opened while the dynamo has its share of the load.

Sometimes it is desirable to have a dynamo which will maintain a constant potential at a point some distance from the switchboard; in this case the series coils will have a few more turns, so as to make up for the fall of potential in the mains; and in Fig. 3 will be found the component curves for a dynamo adjusted for approximately "5 per cent. rise." Curve 1 may be called the "net shunt" falling characteristic made up of the sum of the effects due to the engine change, belt slip, and the fall of potential in the armature circuits represented respectively by the Curves 3, 4 and 5. Curve 6 shows the rise of voltage due to the current in the series coils, and is greater than the total drop Curve 1 by an amount plotted as Curve 2, which is the net characteristic of the over-compounded dynamo.

Should the demand for current exceed the capacity of one dynamo, the addition of a duplicate machine will render it impossible to maintain a constant potential at the distant centre unless both dynamos are run all the time; for while 45 amperes on one dynamo will cause a net rise at the switchboard of 9.5 volts, the same total current furnished by the pair will only produce a rise of 4.75 volts.

If this want of exact regulation does not require the constant running of two dynamos at times of high load, we meet greater troubles in the process of adding the second unit when the load is too heavy for the first one. From the data given in Fig. 3 it is possible to see what will happen under any given conditions when the machines are put in parallel. I have experimentally verified this method of predicting the actions of compound dynamos, and find it exact enough for all practical purposes.

Suppose one dynamo is loaded, what will be the effect if we connect a new one when its voltage is lower, the same as, or higher than the switchboard? I will take from my notebook the results of some experiments on two dynamos with characteristic curves like Fig. 3, first giving the observed results and then calculating them from the curves.

The armatures were mechanically coupled and therefore at same speed. Voltage of each was 222; 30 amperes were taken from No. 2 dynamo and voltage rose to 228, while that of No. 1 fell to 212; then by a double-pole switch No. 1 was put in parallel. Momentarily No. 2 tended to overload and drive No. 1 as a motor, but in a few seconds the load became steady at a voltage of 222, No. 1 furnishing 18 and No. 2 12 amperes. Now by calculation from curves of Fig. 3:

No. 1.	No. 2.	
222.	222.	Volts at switchboard with no load.
−7.5	−7.5	Curve 4. Drop due to speed change when a current of 30 amperes was taken from No. 2.
214.5	214.5	
	−8.	Curve 5. Armature drop with 30 amperes.
	206.5	
	+21.5	Curve 6. Rise from 30 amperes in series coils.
	228.0	Switchboard voltage with 30 amperes output.

Put in parallel with same load, so no change is to be made for speed change. From Curve 6 we see that the change of half of the current from the series coil of No. 2 to No. 1 will raise No. 1.

No. 1.	No. 2.	
214.5	228.0	No. 1 with no load and 30 amperes on No. 2 and then put in parallel.
+12.0	−12.0	Curve 6. Change in voltage with change of half current from series coils of No. 2 to series coils of No. 1.
226.5	216.0	
−4.	+4.	Curve 5. Suppose each armature carried one-half the current then there would be a drop in No. 1 and a rise in No. 2.
222.5	220.0	

We must now add a current to the highest voltage dynamo, or No. 1, that will cause a drop of one-half of 222.5 — 220 volts, which from Curve 5 will be 4.7 amperes.

Then the voltage of the combination will be 221.2; and dynamo 1 will deliver 15 + 4.7 = 19.7 amperes, and dynamo 2, 15 — 4.7 = 10.3 amperes.

Calculated 19.7 amperes, dynamo 1; 10.3 amperes, dynamo 2. Voltage of 221.2.

Measured 18 amperes, dynamo 1; 12 amperes, dynamo 2. Voltage of 222.

Take, for another example, the case when one of these dynamos was at full load and the new machine was brought up to exact voltage and then put in parallel, and applying these methods we shall see that it may happen that all currents may be cut off by the melting of a fuse.

Dynamo No. 1 at 220 volts and no load, then as the load of 45 amperes comes on, the switchboard voltage will be about 230 volts.

220	
−11.2	Drop due to load. Curve 4.
208.8	
−11.7	Drop in armature. Curve 5.
197.1	
+32.5	Rise from series coil. Curve 6.
229.6	Volts at switchboard.

Here the switch is closed.

No. 1.		No. 2.
229.6		229.6
−16.2	22½ amperes in series coil. Curve 6	+16.2
213.4		245.8 Armature voltage.
+ 11.7	Curve 5, to find internal voltage.	
225.1	Armature voltage.	

245.8 Armature voltage No. 2.
225.1 Armature voltage No. 1.

20.7 Difference of armature voltages.
11.7 Drop in No. 2 with 45 amperes.

2) 9.0 Acting to send reverse current through No. 1.

4.5 Curve 5 corresponds to current of about 17 amperes.

245.8 Armature voltage No. 2
−17.0 Drop with 62 amperes. Curve 5.

228.8 Switchboard voltage.

Dynamo No. 1, which was loaded, has a reverse current of 17 amperes and is driven as a motor, while the new dynamo carries the load and is 17 amperes beyond its rated capacity. We see that the switchboard voltage practically does not change under these conditions, but to offset this there is the sudden change of a loaded dynamo into a partially loaded motor and an overload on the incoming dynamo. Such changes would be accompanied by much sparking at the brushes and the liability of thrown belts or blown fuses. Then we may say that if the new dynamo is of lower voltage when connected the voltage will change considerably, but there will be no shock to the dynamos; if the new dynamo is at the same voltage, then the voltage will remain about constant and the armatures will receive a shock; if the new machine is still higher, then the shock will be very severe and the voltage will rise. I had no time for taking readings on the last experiment, but I did notice that the needle of a 150 ampere instrument was out of sight before a switch could be opened.

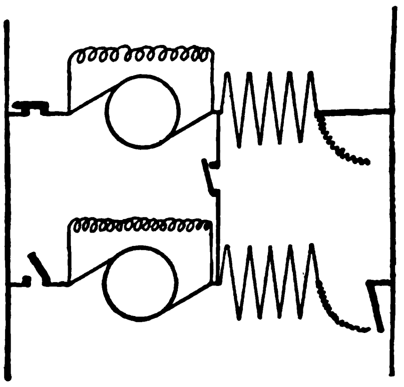


FIG. 4.

There is a very safe and simple method of throwing in a new dynamo, which does not, however, prevent a change in the switchboard voltage unless a special switch is used, as shown in Fig. 4, constructed in such a way that the equalizing connection is first made and then the outside end of the series coil gradually connected by a switch with a few resistance points in it, while at the same time the magnetizing effect of the shunt coil of the loaded dynamo is increased to make up for the loss in the series coil. In this way the series coils can be put in parallel with no jump in the voltage. If, however, there are many similar dynamos in the plant, it might be that the change produced by throwing in a series coil without its armature would not produce a greater change than would be allowable; in such a case the safest way is to connect first the series coils, then rapidly adjust the armature voltage by the voltmeter, or, if in a great hurry, by the looks of the pilot lamps, and then close the armature switch, well knowing that the steep net falling characteristic of the armature circuit will prevent an overload.

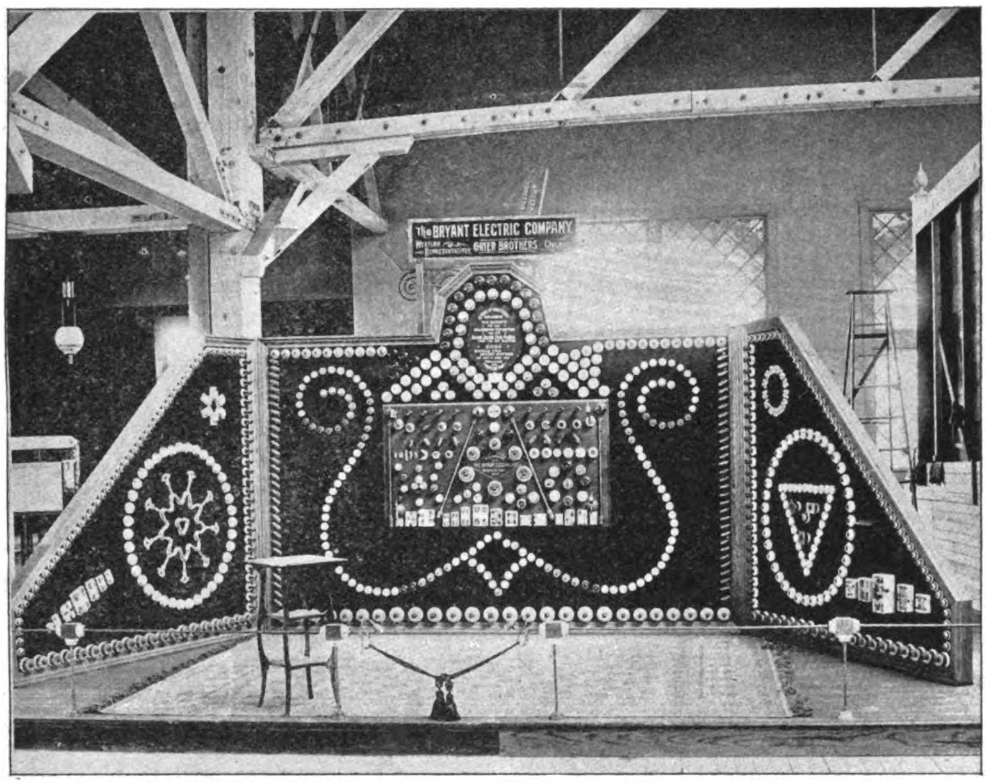
It is now clear that when we wish such dynamos to run together we must first adjust the resistances of all the series coils and connections so that when a current is passing through them but not through the armatures the armature voltages must be equally affected, and also see that the armature circuits are so arranged as to give the same net falling characteristics independent of the series coils. It is necessary for good compounding to have the brushes set once for all, and in all well-designed dynamos it is possible to find a point where there will be no excessive sparking. An easier although not so good a way to adjust is to find the best point for the lead and then alter the resistances of the series coils until all dynamos have the same net characteristics; but the rise of voltage due simply to the flow through all the series coils will in this case be different in different dynamos, and there will be a little more difficulty in adding a new dynamo, and a tendency to overload.

---

*Abstract from "Technology Quarterly," Vol. V, No. 4, read March 23, 1893.

Nearly all of the compound dynamos in the market for the last few years are purposely built with too many turns in the series coil, and then a shunt of German silver is adjusted by trial at the factory until the voltage at the terminals shows the wished for "0 per cent. rise," or whatever it may be. Now for any one dynamo running under the conditions of the experimental trial this method is simple and perfectly correct; but when such dynamos are run together in multiple it is of no service, and has no effect on the relative actions of the series coils of the dynamos, because of the fact that all coils and all shunts become parallel conductors, and therefore traversed by currents inversely proportional to their resistances. These shunts then merely diminish the total flow of current through the series coils, but in no way do they serve to adjust the effect of the series coils relatively to each other. If it should happen that one dynamo was very much over-compounded and then shunted for the "0 per cent. rise," and another only very slightly over-compounded and consequently only slightly shunted, it is plain that when the shunted series coils are in parallel the shunts will have only the effect of affording a path for a part of the total flow of current, and consequently could be wired up in any convenient place on the switchboard. These two above-mentioned dynamos would then be dissimilar over-compounded machines working in parallel, and in all probability an increasing load would be largely carried by the dynamo with most turns in the series coil, because an increase in total current flowing through the series coils would promote the voltage of this dynamo faster than that of the other. This will be the familiar condition we often see in power plants where the average load is equally divided, while an overload is taken quicker by the dynamo which takes the less at light loads, that is, the one in which the series coils have greatest effect.

In order to make such dynamos work properly it is best to examine the lead and the wiring, and, if possible, give the armatures similar net falling characteristics, and then, by the use of copper or German silver ribbon, slightly change the resistance of the series coils until all armatures are equally affected by the flow of current in the series coils; a single large shunt may be connected at any part of the bars to which the series coils are attached, or perhaps better, each machine may have a shunt across the series connections at the switchboard, on the dynamo side of the main three-pole switch, so that the total shunting capacity varies as it ought with the number of dynamos running.

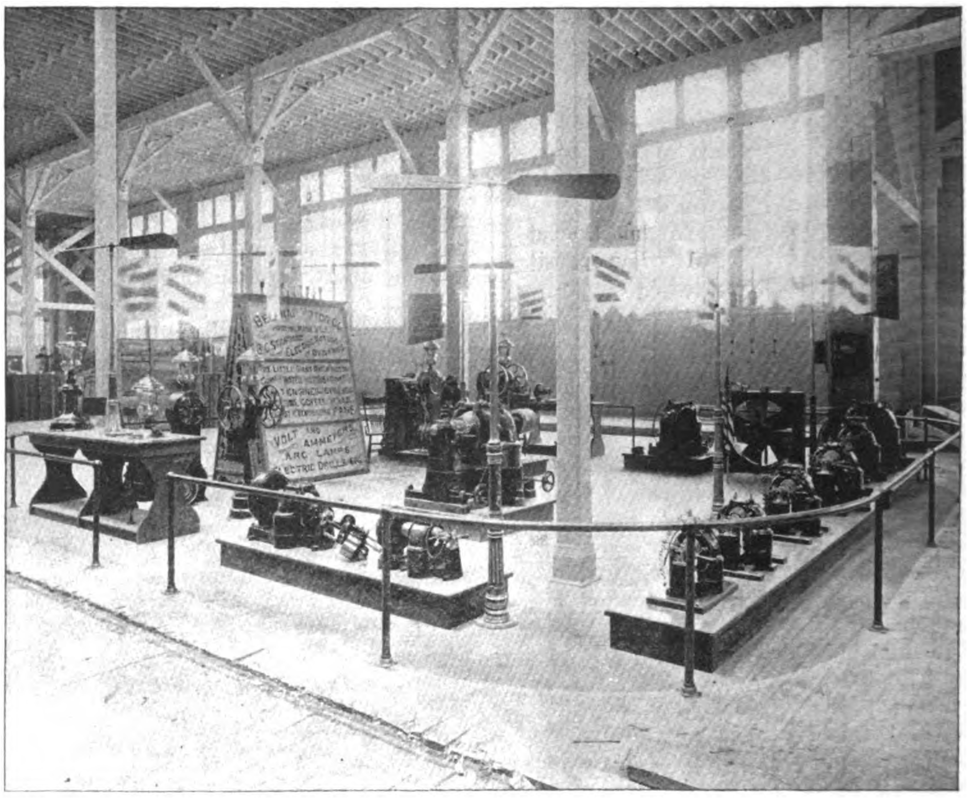


Bryant Electric Company's World's Fair Exhibit.

World's Fair Notes.

A very interesting exhibit, which is just being completed, is furnished by the Japan Government. Owing to the fact that Japan is making a very extensive display in nearly all of the Exposition buildings, and that its exhibits are installed by Japanese only, their display in the Electricity Building has been somewhat delayed. The section assigned to the Japanese Government is located in the northeast corner on the main floor of the building. It consists principally of instruments from the technical laboratory of the University of Tokio and also of instruments used by the Government in detecting movements of the earth caused by earthquakes. Among the latter are the following instruments: The siesmograph, a machine for writing the earth's horizontal and vertical movements on a smoked glass plate. The rate at which the plate moves is also marked by an electrical time ticker. The tremometer is one form of an instrument used to record the slight movements of the earth, usually called earth tremors. The action of the machine is to close a circuit at regular intervals which will cause a spark from an induction coil to perforate a band of paper which moves over a brass table. If the pointer from which the spark projects is stationary, a series of holes following one another in a straight line will be the result, but if the pointer is moving the line will be a curved one, the curves indicating the direction and extent of the motion. Among the other exhibits shown is an electrical contact maker, an electric clock and a safety lamp.

Some of the instruments in this display are of historical value as they were the ones used in the great earthquake of October 28, 1891, from which much important data was obtained.



Belknap Motor Company's World's Fair Exhibit.

The Western Electric Company during the past week have won the gratitude of a large portion of the visiting public at the Exposition by placing nearly 200 chairs and benches around their space in the Electricity Building. By performing this charitable act they not only hold the attention of the visitors longer but also keep a larger crowd interested in their display than would otherwise be possible. If the rest of the exhibitors in the Electricity Building would follow the good example set by the Western Electric this building would soon become the most popular one on the grounds. The small electric scenic theatre, which is a part of the Western's exhibit, is soon to be moved into larger quarters. A space twenty-two by forty-eight feet square has been secured by the company and is being prepared for the theatre. It will have a seating capacity for one hundred and twenty-five people. Two exhaust fans for purifying and cooling the air will be in operation during each performance. The theatre will be free to the public, performances being given every half hour.

The "C. & C" Electric Motor Company, owing to a lack of power, have been unable to get their exhibit in operation before the public until last week. They have now completed connections, and are showing one of their 50 horse power motors running a generator which in turn is used to generate current for an electric pump, an electric hoist and a fan. Besides these, seven other machines are also exhibited. A fifteen-panel switchboard, divided into two sections for a 500 and a 110 volt current, forms a very neat and attractive part of the exhibit.

The exhibits of the Bryant Electric Company and the Belknap Motor Company are illustrated in this issue, the photographs having arrived too late for last week.

A New Electric Railway System.

Operated with Insulated Trolley Wires in a Conduit.

An experimental electric railway has just been put in operation at Coney Island which is equipped with a conduit containing insulated trolley wires with which the trolley shoe under the car makes contact by means of switches placed at intervals along either side of the conduit.

The objects of this arrangement are to avoid the use of overhead wires, secure a conduit system which will not be liable to electrical leakage due to moisture or water in the conduit, and incidentally to make use of a higher voltage than is commonly used.

The experiment is being undertaken by the Universal Electric Company of New York, who own patents covering the system, to demonstrate the practicability of this method of electric railway propulsion, and the present line, which has been in operation but a few days, has so far given every evidence of satisfaction.

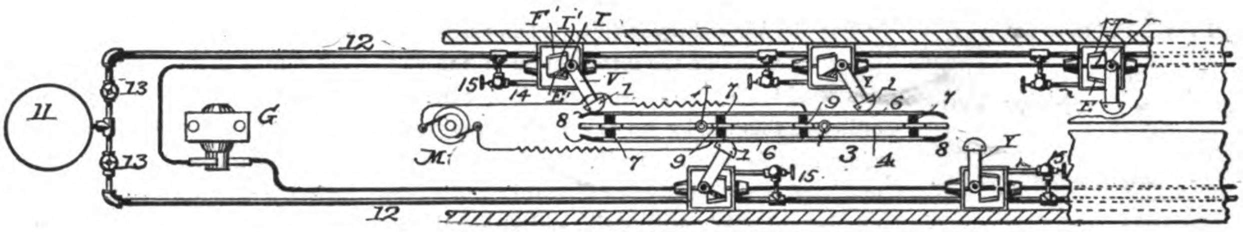


FIG. 1.

Reference to the following figures will explain the details of the system. Fig 1 shows a diagrammatic sketch of the plant and the apparatus which it contains. The station generator G is connected to the two trolley lines in the conduit, the outgoing and return circuit being placed on opposite sides. This circuit, unlike the usual trolley wire, is a heavily insulated lead-covered cable into which switches (shown in Fig. 2) are let in at distances of seven feet, those on one side being midway between the ones on the opposite side of the conduit. Attached to the car is a shoe which passes between the arms (1) of the switches from which the current is taken. The shoe is about twelve feet in length so that its two sides are always in contact with one or two switch arms, and it is held in line with the centre of the conduit by means of several vertical arms or rollers which travel in the slot. The current is led from the brass strips (7) on the shoe to the car motor.

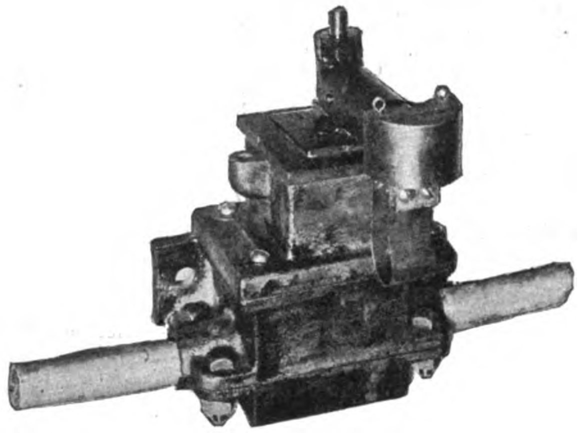

FIG. 2.

The switch boxes are filled with oil which is supplied by a system of piping (12).

Fig. 2 shows a general view of one of the switches which is explained in detail in Figs. 3 and 4. The box is composed of two parts, the lower section of which B has the cable passing through it. The insulation is removed from the cable inside the box and a contact piece E is clamped on the wire. A vertical brass rod I passes through the box, the lower end being provided with a brush L which stands normally between the two lugs of the piece E, and is brought into contact with either by the turning of the shaft I.

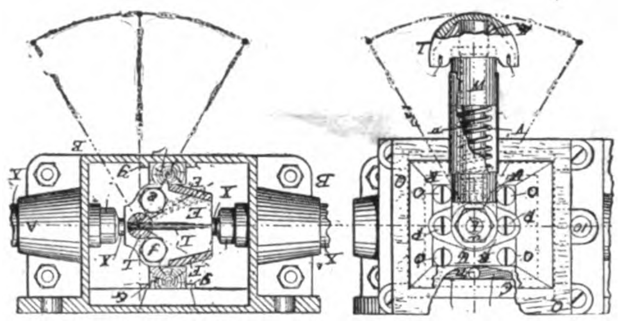

FIG. 4.

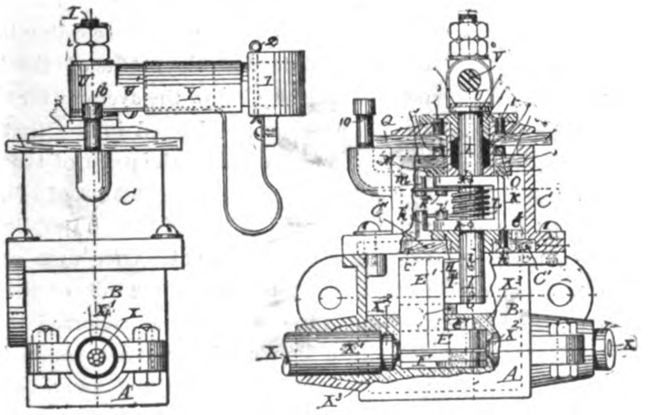

FIG. 3.

From the foregoing it will be seen that the contact arms are normally out of circuit and only carry the current when moved either way by the trolley shoe under the car. The contact arm is arranged to yield inwardly if the direction of the motion of the car is reversed, and the shoe is sufficiently flexible to conform to the sharpest possible curve of the track. In this way the leakage of the current due to water in the conduit is eliminated, and for this reason it becomes feasible to make use of currents of much higher voltage than is commonly used, thereby reducing the amount of copper necessary for the lines.

Fig. 5 shows a section of the road at Coney Island with the top of the conduit removed.

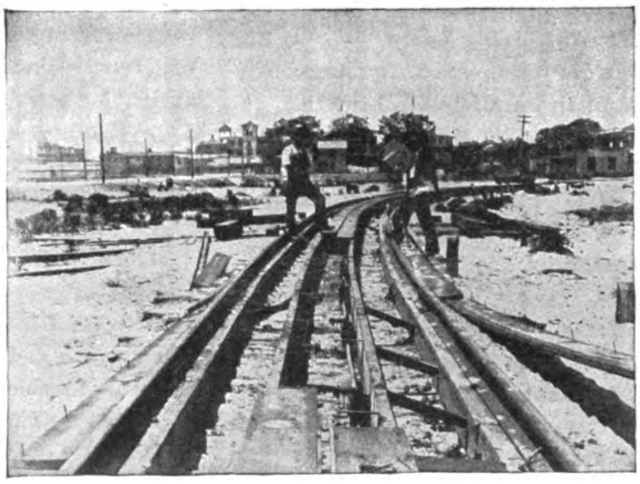

FIG. 5.

The officers of the company are: T. C. Buck, president; Julian Myers. vice-president; R. T. Keen, treasurer, and Albert Stetson, general manager.

The Northwestern Electrical Association.

The convening of this association at Madison, Wis., on the 19th and 20th inst., promises to be an event of great interest to all the participants. The programme for both days is as follows:

19th—Forenoon—Organization and President's Address. Afternoon—"Corliss Compound Engines," by E. L. Dobell, Sheboygan; "Russell Tandem Compound Engines," ——; "Gas Engines Applied to Electric Light Work." Geo. A. Farwell, Waukesha. Evening—"Alternating Current Phenomena" (with experiments), Geo. Cutter, Chicago; "Economy in the Use of Meters," Prof. Jackson, Madison.

20th—Forenoon—"Management of Central Stations," ——; "Average Charges and Methods of Charging of Northwestern Central Stations," P. H. Korst, Racine; "The Business End of Electricity," H. C. Thom, Madison. Afternoon and Evening—Pleasure.

The Hartford, Conn., Chief of Police employs electricity in putting an end to the life of vagrant dogs found in the streets unmuzzled and unmarked. In the rear of the station house he has had a cage rigged up with electrical connections. The cage is just large enough for a dog to stand in. The fore feet of the animal rest upon one electrode and his hind feet upon the other. When he is in position an electric current is switched on and death quickly ensues.

Electric Railway Progress.

The increasing number of plans which are appearing almost constantly for electric conduit and storage battery street car propulsion must be taken as indicative of the trend in which electrical engineers are preparing to make future advances in the electric railway field in which the overhead trolley now holds almost exclusive sway.

The electric railway industry commenced on a practical extent on the introduction of the single overhead trolley with return circuit over the rails, although this was by no means the actual beginning of this work. Trolley roads with double overhead circuits had been the subject of a great number of trials previously, and although they proved impracticable at the time, this was more through the fault of the mechanical constructions attempted than through any inherent electrical defects.

The early roads were generally run at low voltages, ranging from two hundred to three hundred and fifty volts, necessitating the use of very large trolley wires. The trolleys were four-wheel carriages, weighing from thirty to forty pounds, which traveled on top of the wires and had a flexible cable connecting them to the car. The slightest obstruction, or even a change of speed, often threw these trolleys on to the cars and they not infrequently went through the roofs.

On one road of this construction a small boy with a long pole to replace the trolley was carried on the roof of each car as part of the regular equipment, and a ladder was fixed to the rear platform to give easy access to the roof.

The advent of the single under-running trolley, which may be considered as merely a mechanical change, solved most of the former difficulties, and the use of five hundred volts, which was at first denounced as too dangerous to permit, put the electric railway practically in its present condition in which it has supplanted more than one-quarter of the horse railways in this country.

Now that the overhead trolley system has thoroughly established itself as a permanent and practical institution the demand for refinements both from æsthetic and engineering standpoints are heard, the public asking for the removal of all overhead wires and the railway companies for apparatus of higher efficiency and greater economy of operation.

The prejudice which has opposed the introduction of trolley wires in some cities appears as unconquerable as it is unfounded, and this has been the chief incentive to the invention of conduit systems and storage battery cars both of which are feasible where the traffic is sufficient to warrant the high first cost. This is probably the case only in the largest cities, and the overhead system will doubtless continue to be the rule in most places.

The most serious objections which the present roads present from an engineering view are the leakage of current in wet weather and the electrolytic action on underground pipes caused by the ground return in cases where heavy currents are used. These are avoided entirely in the storage battery cars and in the double trolley conduit systems but at a large additional expense over present systems.

The conduit system, which has been generally avoided on account of its cost, has been found to fill all requirements in the case of the Budapest railway, but if the question of insulation has been solved there seems to be no reason why the cost of equipment should not be very much reduced by using a current of much higher voltage than is usually employed and thus reduce the amount of copper in the conductors. This would amount to a large item in any road of sufficient size to warrant the expense of a conduit system.

While the field for such roads would be limited, work in this direction is going on which gives promise of eventual success; at the same time the present overhead systems will be pretty sure to be found the most available for most places.

* * *

Time for a Change.

The present condition, not alone of General Electric shares in the stock market, but of the actual selling business of that company, proves conclusively that ELECTRICITY has been right from the beginning in its main contentions—that the policy of the company is all wrong, and that the management is incompetent.

We feel certain that no suggestion which we could make in regard to the policy of the company would be well received by the Board of Directors. They seem to think that ELECTRICITY is an enemy when in reality it is the best friend they have. While we have, in the line of our duty to the trade, to legitimate investors, and to the cause of honest business methods, told a great many plain truths, we have not been instigated by malice. And sooner or later the respectable and fair-minded men among the Directors will acknowledge that the criticism of ELECTRICITY has been wholesome and beneficial to their own best interests.

While, as we have said, it is a little too soon to expect a change of policy, we believe there is not a member of the Board of Directors but realizes that a change in management is imperative. The business which would naturally come to the Trust is going elsewhere, and according to the latest official statement the profits of the last five months are away below the average for the eight months previous (as claimed in the first annual statement). Moreover, the price of the stock in the market is superabundant proof of mismanagement, or at least proof that the public believes there is mismanagement. Of course all stocks are low; but the financial records of the day fail to disclose the common and preferred stock and debenture bonds of any other sound dividend paying company all selling away below par. When an 8 per cent. stock cannot be forced above 72 or 73 something is wrong.

In view of the repeated statements of various members of the Board—all, all honorable men—that the company's finances are sound, we must, of course, believe this to be the fact?

What then is wrong? Clearly nothing but lack of confidence in the management.

It is therefore natural to suppose that the Board are casting about in secret for a new president.

There is only one man in the electrical field to-day who is the superior of Mr. Coffin in ability to carry out the present policy of the Electric Trust. This One Man is hopelessly modest, and since it has been the steadfast purpose of Electricity to see that virtue gets its proper reward, we feel perfectly justified in again bringing forward our candidate, Mr. Richard Truthful McDonald.

While Mr. McDonald has abundantly proved his ability, there is danger that he would be overlooked by the Board but for our advocacy of his cause. We have heretofore outlined Mr. McDonald's characteristics; but we shall persistently revert to this subject until our man wins.

The Golden Rule of Our Candidate is, " If you don't do others, they'll do you."

What more appropriate motto could there be for the General Electric Company under its present policy?

* * *

The *Street Railway and Electrical News*, published, as we suppose from its official date line, somewhere in the green fields between Minneapolis and St. Paul, has a few words to say about Electricity in its latest issue. We thank our contemporary for its kind attention, and have put its name down in our notebook along with our other friends. Candor compels the statement, however, that the opinions of a journal getting 30 per cent. of its patronage from the Electric Trust will not carry much weight in these parts.

* * *

The latest official statement of progress given out by the promoters of the St. Louis-Chicago electric road scheme is that twenty miles of road have been built. As long ago as March 1 it was claimed that twenty miles of road had been built, and we are therefore led to believe that business is not rushing with the Through-by-Lightning Company.

All visitors to the World's Fair will be welcome at the booth of Electricity, Section Y, Northwest Gallery, Electricity Building.

Another Statement.

General Electric's Record for Five Months.

The General Electric Company has declared its regular quarterly dividend of 2 per cent., and has issued the following statement of its business for the five months ending May 1 :

Net profits $1,391,721, net profit for June (partly estimated) $360,000, total $1,751,729, less five months' accrued interest on debentures $208,333; available for stocks $1,543,396, less five months' accrued dividends on preferred stock at 7 per cent., $124,013, and five months' accrued dividends on common stock at 8 per cent. $1,014,180, total $1,138,193. Net surplus for five months over and above accrued interest and dividends $405,202. The above profits are exclusive of all license and royalty stocks and other securities received since January 31.

Electric Lighting in Spain.

Spaniards although slow in the adoption of many improvements are decidedly not so in regard to electric lighting. A large number of the principal towns as well as many very small ones have installations of their own. The latest venture is on the part of the owner of some water power near the two very limited towns, Elgalbar and Eibar, in the Spanish province of Viscaya; these towns will shortly be supplied with electric current for both lighting and power purposes.

The necessary working power will be furnished by the water of the river Dova. A newly erected system of dams supplies an available fall of 8.05 meters and 300 H. P. A " Hercules" turbine of 130 H. P. will be set up and used for the direct propulsion of a rotatory current dynamo of 80,000 watts which is supplied by Messrs. Siemens & Halske of Berlin. The current produced by the dynamo has a tension of 120 volts which is increased to 50,000 volts by means of rotatory transformers. Elgalbar, the smaller of the two towns, contemplates chiefly electric lighting; there are here to be 80 lamps for street lighting and about 140 for private consumption. In the more industrial town, Eibar, the demand for electric power takes the first prominence. Numerous locksmiths and other manufacturers have applied for the supply of electric power and the firm of Messrs. Siemens & Halske have already received orders for a considerable number of electromotors of from 1 to 25 H. P. One hundred and twenty lamps are required for street lighting and about 400 for private purposes.

It is expected that the completion of the primary station will shortly be necessary. The entire installation is a private undertaking of the owner of the water power.

Injunctions Granted.

Ten Days Allowed to Procure Other Lamps.

Judge Lacombe, of the United States Circuit Court, has granted temporary injunctions to the Edison Electric Illuminating Company of New York against the Holland House and the Imperial Hotel, prohibiting them from using incandescent electric lamps infringing the Edison patent, under which, as is well known, the Edison Electric Illuminating Company of New York is sole licensee in the city of New York. The hotels in question were given ten days to arrange for other means of illumination.

This decision was not unexpected, and will create no surprise.

Personal.

Mr. M. M. Merritt, of the Boston Incandescent Lamp Company, met with a somewhat serious accident in Cleveland recently and was confined to his room for several days.

Mr. Nelson W. Perry, editor of the *Electrical World*, and Miss Marie Eugenia Bedell were married in Brooklyn on the evening of June 28. Mr. Perry and his bride will spend the summer in Chicago.

Mr. Herbert Laws Webb, of the Electric Selector and Signal Company, has lately returned from a trip abroad, taken in the interest of his company.

Mr. S. G. Booker, of the Fidelity Carbon Company of St. Louis, has been in the city for the past week.

Mr. W. L. Garrison, of Boston, has sold out his entire interest in the Brockton Edison Station.

Mr. Morgan Brooks, of the St. Paul Engineering and Supply Company, who has been in the city for some time, has returned to the West.

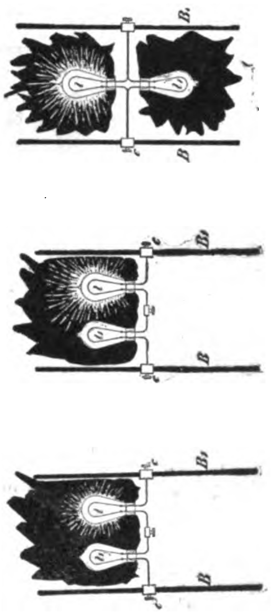
Mr. W. C. Bryant, of the Bryant Electric Company of Bridgeport, was in New York last week.

Mr. Arthur E. Bowers has been appointed New York manager for Claflin & Kimball, and will push the Novak lamp.

ON LIGHT AND OTHER HIGH FREQUENCY PHENOMENA.—VI.

BY NIKOLA TESLA.[*]

ON THE LIGHT PHENOMENA PRODUCED BY HIGH-FREQUENCY CURRENTS OF HIGH POTENTIAL AND GENERAL REMARKS RELATING TO THE SUBJECT.



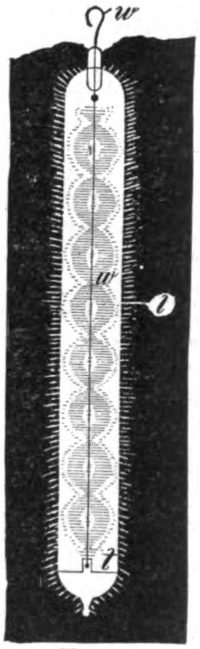


Fig. 22a, Fig. 22b, Fig. 22c.— Fig. 23.
Showing the Effect of the Presence of a Gaseous Medium.

Fig. 23.—Curious Incandescence of a Wire.

Returning now to the light effects which it has been the chief object to investigate, it is thought proper to divide these effects into four classes: 1. Incandescence of a solid. 2. Phosphorescence. 3. Incandescence or phosphorescence of a rarefied gas, and 4. Luminosity produced in a gas at ordinary pressure. The first question is, How are these luminous effects produced? In order to answer this question as satisfactorily as I am able to do in the light of accepted views and with the experience acquired, and to add some interest to this demonstration, I shall dwell here upon a feature which I consider of great importance, inasmuch as it promises, besides, to throw a better light upon the nature of most of the phenomena produced by high-frequency electric currents. I have on other occasions pointed out the great importance of the presence of the rarefied gas, or atomic medium in general, around the conductor through which alternate currents of high frequency are passed, as regards the heating of the conductor by the currents. My experiments, described some time ago, have shown that the higher the frequency and potential difference of the currents the more important becomes the rarefied gas in which the conductor is immersed, as a factor of the heating. The potential difference, however, is, as I then pointed out, a more important element than the frequency. When both of these are sufficiently high, the heating may be almost entirely due to the presence of the rarefied gas. The experiments to follow will show the importance of the rarefied gas, or generally of gas at ordinary or other pressure as regards the incandescence or other luminous effects produced by currents of this kind.

I take two ordinary 50-volt 16 C. P. lamps which are in every respect alike, with the exception that one has been opened at the top and the air has filled the bulb while the other is at the ordinary degree of exhaustion of commercial lamps. When I attach the lamp which is exhausted to the terminal of the secondary of the coil, which I have already used, as in experiments illustrated in Fig. 15a for instance, and turn on the current, the filament, as you have before seen, comes to high incandescence. When I attach the second lamp, which is filled with air instead of the former, the filament still glows, but much less brightly. This experiment illustrates only in part the truth of the statements before made. The importance of the filament's being immersed in rarefied gas is plainly noticeable but not to such a degree as might be desirable. The reason is that the secondary of this coil is wound for low tension, having only 150 turns, and the potential difference at the terminals of the lamp is therefore small. Were I to take another coil with many more turns in the secondary, the effect would be increased, since it depends partially on the potential difference, as before remarked. But since the effect likewise depends on the frequency, it may be properly stated that it depends on the time rate of the variation of the potential difference. The greater this variation the more important becomes the gas as an element of heating. I can produce a much greater rate of variation in another way, which, besides, has the advantage of doing away with the objections which might be made in the experiment just shown, even if both the lamps were connected in series or multiple arc to the coil, namely, that in consequence of the reactions existing between the primary and secondary coil the conclusions are rendered uncertain. This result I secure by charging from an ordinary transformer, which is fed from the alternating current supply station, a battery of condensers, and discharging the latter directly through a circuit of small self-induction, as before illustrated in Figs. 19*a*, 19*b*, 19*c*.

---

[*] A lecture delivered before the Franklin Institute at Philadelphia, Feb. 24, 1893, and before the National Electric Light Association at St. Louis, Mo., March 1, 1893.

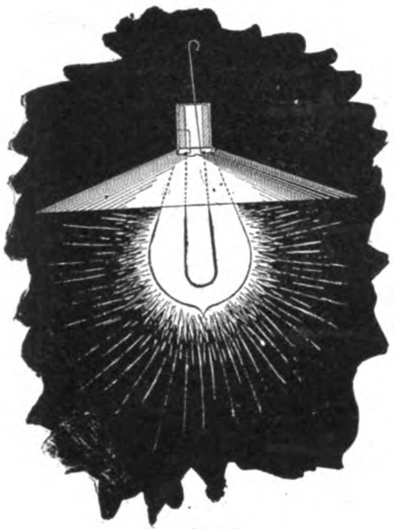

Fig. 24

UTILIZING THE HEATING EFFECT OF CONDUCTION CURRENT AND BOMBARDMENT.

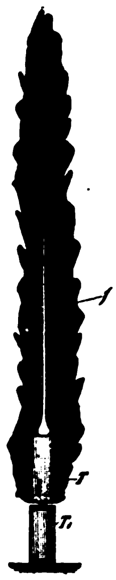

Fig. 25

FIG. 25.—ILLUSTRATING LATERAL DIFFUSION.

In Figs. 22*a*, 22*b* and 22*c* the heavy copper bars BB$_1$ are connected to the opposite coatings of a battery of condensers, or generally in such way that the high frequency or sudden discharges are made to traverse them. I connect first an ordinary 50-volt incandescent lamp to the bars by means of the clamps *c c*. The discharges being passed through the lamp, the filament is rendered incandescent. though the current through it is very small, and would not be nearly sufficient to produce a visible effect under the conditions of ordinary use of the lamp. Instead of this I now attach to the bars another lamp exactly like the first, but with the seal broken off, the bulb being therefore filled with air at ordinary pressure. When the discharges are directed through the filament, as before, it does not become incandescent. But the result might still be attributed to one of the many possible reactions. I therefore connect both the lamps in multiple arc as illustrated in Fig. 22*a*. Passing the discharges through both the lamps again the filament in the exhausted lamp l glows very brightly while that in the non-exhausted lamp l_1 remains dark as previously. But it should not be thought that the latter lamp is taking only a small fraction of the energy supplied to both the lamps; on the contrary, it may consume a considerable portion of the energy and it may become even hotter than the one which burns brightly. In this experiment the potential difference at the terminals of the lamps varies in sign theoretically three to four million times a second. The ends of the filaments are correspondingly electrified, and the gas in the bulbs is violently agitated and a large portion of the supplied energy is thus converted into heat. In the non-exhausted bulb, there being a few million times more gas molecules than in the exhausted one, the bombardment, which is most violent at the ends of the filament in the neck of the bulb, consumes a large portion of the energy without producing any visible effect. The reason is that, there being many molecules, the bombardment is quantitatively considerable, but the individual impacts are not very violent, as the speeds of the molecules are comparatively small owing to the small free path. In the exhausted bulb, on the contrary, the speeds are very great and the individual impacts are violent and therefore better adapted to produce a visible effect. Besides, the convection of heat is greater in the former bulb. In both the bulbs the current traversing the filaments is very small, incomparably smaller than that which they require on an ordinary low-frequency circuit. The potential difference, however, at the ends of the filaments is very great and might be possibly 20,000 volts or more if the filaments were straight and their ends far apart. In the ordinary lamp a spark generally occurs between the ends of the filament, or between the platinum wires outside, before such a difference of potential can be reached.

It might be objected in the experiment before shown that the lamps, being in multiple arc, the exhausted lamp might take a much larger current and that the effect observed might not be exactly attributable to the action of the gas in the bulbs. Such objections will lose much weight if I connect the lamps in series, with the same result. When this is done and the discharges are directed through the filaments it is again noted that the filament in the non-exhausted bulb l_1 remains dark, while that in the exhausted one (l) glows even more intensely than under its normal conditions of working, Fig. 22*b*. According to general ideas the current through the filaments should now be the same were it not modified by the presence of the gas around the filaments.

At this juncture I may point out another interesting feature, which illustrates the effect of the rate of change of potential of the currents. I will leave the two lamps connected in series to the bars BB$_1$ as in the previous experiment, Fig. 22*b*, but will presently reduce considerably the frequency of the currents, which was excessive in the experiment just before shown. This I may do by inserting a self-induction coil in the path of the discharges, or by augmenting the capacity of the condensers. When I now pass these low-frequency discharges through the lamps the exhausted lamp l again is as bright as before but it is noted also that the non-exhausted lamp l_1 glows though not quite as intensely as the other. Reducing the current through the lamps, I may bring the filament in the latter lamp to redness, and though the filament in the exhausted lamp l is bright, Fig. 22*c*, the degree of its incandescence is much smaller than in Fig. 22*b* when the currents were of a much higher frequency.

In these experiments the gas acts in two opposite ways in determining the degree of the incandescence of the filaments, that is, by convection and bombardment. The higher the frequency and potential of the currents, the more important becomes the bombardment. The convection on the contrary should be the smaller the higher the frequency. When the currents are steady there is practically no bombardment, and convection may therefore with such currents also considerably modify the degree of incandescence and produce results similar to those just before shown. Thus, if two lamps exactly alike, one exhausted and one not exhausted, are connected in multiple arc or series to a direct-current machine, the filament in the non-exhausted lamp will require a considerably greater current to be rendered incandescent. This result is entirely due to convection and the effect is the more prominent the thinner the filament. Professor Ayrton and Mr. Kilgour some time ago published quantitative results concerning the thermal emissivity by radiation and convection in which the effect of thin wires was clearly shown. This effect may be strikingly illustrated by preparing a number of small short glass tubes, each containing through its axis the thinnest obtainable platinum wire. If these tubes be highly exhausted, a number of them may be connected in multiple arc to a direct-current machine and all of the wires may be kept at incandescence with a smaller current than that required to render incandescent a single one of the wires if the tube be not exhausted. Could the tubes be so highly exhausted that convection would be nil, then the relative amounts of heat given off by convection and radiation could be determined without the difficulties attending thermal quantitative measurements. If a source of electric impulses of high frequency and very high potential is employed, a still greater number of the tubes may be taken and the wires rendered incandescent by a current not capable of warming perceptibly a wire of the same size immersed in air at ordinary pressure, and conveying the energy to all of them.

I may here describe a result which is still more interesting, and to which I have been led by the observation of these phenomena. I noted that small differences in the density of the air produced a considerable difference in the degree of incandescence of the wires, and I thought that, since in a tube through which a luminous discharge is passed the gas is generally not of uniform density, a very thin wire contained in the tube might be rendered incandescent at certain places of smaller density of the gas while it would remain dark at the places of greater density where the convection would be greater and the bombardment less intense. Accordingly a tube t was prepared, as illustrated in Fig. 23, which contained through the middle a very fine platinum wire w. The tube was exhausted to a moderate degree and it was found that when it was attached to the terminal of a high-frequency coil the platinum wire w would, indeed, become incandescent in patches, as illustrated in Fig. 23. Later a number of these tubes with one or more wires were prepared, each showing this result. The effect was best noted when the striated discharge occurred in the tube, but was also produced when the striæ were not visible, showing that even then the gas in the tube was not of uniform density. The position of the striæ was generally such that the rarefactions corresponded to the places of incandescence or greater brightness on the wire w. But in a few instances it was noted that the bright spots on the wire were covered by the dense parts of the striated discharge, as indicated by l in Fig. 23, though the effect was barely perceptible. This was explained in a plausible way by assuming that the convection was not widely different in the dense and rarefied places, and that the bombardment was greater on the dense places of the striated discharge. It is, in fact, often observed in bulbs that under certain conditions a thin wire is brought to higher incandescence when the air is not too highly rarefied. This is the case when the potential of the coil is not high enough for the vacuum, but the result may be attributed to many different causes. In all cases this curious phenomenon of incandescence disappears when the tube, or rather the wire, acquires throughout a uniform temperature.

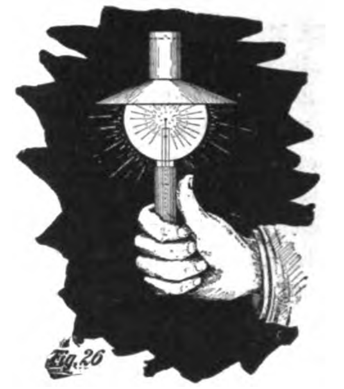

Fig. 26

INCANDESCENCE OF A SOLID.

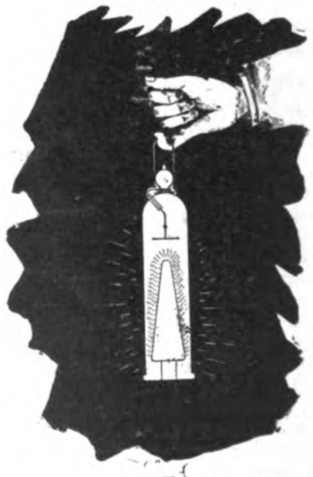

Fig. 27

PHOSPHORESCENCE.

Disregarding now the modifying effect of convection, there are then two distinct causes which determine the incandescence of a wire or filament with varying currents, that is, conduction current and bombardment. With steady currents we have to deal only with the former of these two causes, and the heating effect is a minimum, since the resistance is least to steady flow. When the current is a varying one, the resistance is greater and hence the heating effect is increased. Thus, if the rate of change of the current is very great, the resistance may increase to such an extent that the filament is brought to incandescence with inappreciable currents, and we are able to take a short and thick block of carbon or other material and bring it to bright incandescence with a current incomparably smaller than that required to bring to the same degree of incandescence an ordinary thin lamp filament with a steady or low frequency current. This result is important, and illustrates how rapidly our views on these subjects are changing, and how quickly our field of knowledge is extending. In the art of incandescent lighting, to view this result in one aspect only, it has been commonly considered as an essential requirement for practical success that the lamp filament should be thin and of high resistance. But now we know that the resistance to the steady flow of the filament does not mean anything; the filament might as well be short and thick; for if it be immersed in rarefied gas it will become incandescent by the passage of a small current. It all depends on the frequency and potential of the currents. We may conclude from this that it would be of advantage, so far as the lamp is considered, to employ high frequencies for lighting, as they allow the use of short and thick filaments and smaller currents.

Incandescence or Phosphorescence of Rarefied Gas.

If a wire or filament be immersed in a homogeneous medium, all the heating is due to true conduction current, but if it be enclosed in an exhausted vessel the conditions are entirely different. Here the gas begins to act and the heating effect of the conduction current, as is shown in many experiments, may be very small compared with that of the bombardment. This is especially the case if the circuit is not closed and the potentials of course very high. Suppose a fine filament enclosed in an exhausted vessel be connected with one of its ends to the terminal of a high tension coil and with its other end to a large insulated plate. Though the circuit is not closed, the filament, as I have before shown, is brought to incandescence. If the frequency and potential be comparatively low, the filament is heated by the current passing *through* it. If the frequency and potential, and principally the latter, be increased, the insulated plate need be but very small, or may be done away with entirely; still the filament will become incandescent, practically all the heating being then due to the bombardment. A practical way of combining both the effects of conduction current and bombardment is illustrated in Fig. 24, in which an ordinary lamp is shown provided with a very thin filament which has one of the ends of the latter connected to a shade serving the purpose of the insulated plate, and the other end to the terminal of a high tension source. It should not be thought that only rarefied gas is an important factor in the heating of a conductor by varying currents, but gas at ordinary pressure may become important if the potential difference and frequency of the currents are excessive. On this subject I have already stated that when a conductor is fused by a stroke of lightning the current through it may be exceedingly small, not even sufficient to heat the conductor perceptibly, were the latter immersed in a homogeneous medium.

From the preceding it is clear that when a conductor of high resistance is connected to the terminals of a source of high frequency currents of high potential, there may occur considerable dissipation of energy, principally on the ends of the conductor, in consequence of the action of the gas surrounding the conductor. Owing to this, the current through a section of the conductor at a point midway between its ends may be much smaller than through a section near the ends. Furthermore, the current passes principally through the outer portions of the conductor, but this effect is to be distinguished from the skin effect as ordinarily interpreted, for the latter would or should occur also in a continuous incompressible medium. If a great many incandescent lamps are connected in series to a source of such currents, the lamps at the ends may burn brightly, whereas those in the middle may remain entirely dark. This is due principally to bombardment, as before stated. But even if the currents be steady, provided the difference of potential is very great, the lamps at the ends will burn more brightly than those in the middle. In such case there is no rhythmical bombardment and the result is produced entirely by leakage. This leakage or dissipation into space when the tension is high is considerable when incandescent lamps are used, and still more considerable with arcs, for the latter act like flames. Generally, of course, the dissipation is much smaller with steady than with varying currents.

I have contrived an experiment which illustrates in an interesting manner the effect of lateral diffusion. If a very long tube is attached to the terminal of a high frequency coil, the luminosity is greatest near the terminal and falls off gradually towards the remote end. This is more marked if the tube is narrow.

A small tube, about one-half inch in diameter and twelve inches long, Fig. 25, has one of its ends drawn out into a fine fibre *f* nearly three feet long. The tube is placed in a brass socket T which can be screwed on the terminal T_1 of the induction coil. The discharge passing through the tube first illuminates the bottom of the same, which is of comparatively large section; but through the long glass fibre the discharge cannot pass. But gradually the rarefied gas inside becomes warmed and more conducting and the discharge spreads into the glass fibre. This spreading is so slow that it may take half a minute or more until the discharge has worked through up to the top of the glass fibre, then presenting the appearance of a strongly luminous thin thread. By adjusting the potential at the terminal the light may be made to travel upwards at any speed. Once, however, the glass fibre is heated the discharge breaks through its entire length instantly. The interesting point to be noticed is that the higher the frequency of the currents, or in other words, the greater relatively the lateral dissipation, at a slower rate may the light be made to propagate through the fibre. This experiment is best performed with a highly exhausted and freshly made tube. When the tube has been used for some time the experiment often fails. It is possible that the gradual and slow impairment of the vacuum is the cause. This slow propagation of the discharge through a very narrow glass tube corresponds exactly to the propagation of heat through a bar warmed at one end. The quicker the heat is carried away laterally the longer time it will take for the heat to warm the remote end. When the current of a low frequency coil is passed through the fibre from end to end, then the lateral dissipation is small and the discharge instantly breaks through almost without exception.

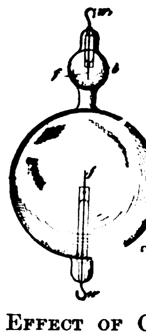
Luminosity of Gas at Ordinary Pressure.

After these experiments and observations, which have shown the importance of the discontinuity or atomic structure of the medium and which will serve to explain, in a measure at least, the nature of the four kinds of light effects producible with these currents, I may now give you an illustration of these effects. For the sake of interest I may do this in a manner which to many of you might be novel. You have seen before that we may now convey the electric vibration to a body by means of a single wire or conductor of any kind. Since the human frame is conducting, I may convey the vibration through my body.

First, as in some previous experiments, I connect my body with one of the terminals of a high tension transformer and take in my hand an exhausted bulb which contains a small carbon button mounted upon a platinum wire leading to the outside of the bulb, and the button is rendered incandescent as soon as the transformer is set to work (Fig. 26). I may place a conducting shade on the bulb which serves to intensify the action, but is not necessary. Nor is it required that the button should be in conducting connection with the hand through a wire leading through the glass, for sufficient energy may be transmitted through the glass itself by inductive action to render the button incandescent.

Next I take a highly exhausted bulb containing a strongly phosphorescent body, above which is mounted a small plate of aluminum on a platinum wire leading to the outside, and the currents flowing through my body excite intense phosphorescence in the bulb, Fig. 27. Next again, I take in my hand a simple exhaust tube, and in the same manner the gas inside the tube is rendered highly incandescent or phosphorescent, Fig. 28. Finally, I may take in my hand a wire, bare or covered with thick insulation, it is quite immaterial; the electric vibration is so intense as to cover the wire with a luminous film, Fig. 29.

A few words must now be devoted to each of these phenomena. In the first place, I will consider the incandescence of a button or of a solid in general, and dwell upon some facts which apply equally to all these phenomena. It was pointed out before that when a thin conductor, such as a lamp filament for instance, is connected with one of its ends to the terminal of a transformer of high tension the filament is brought to incandescence partly by a conduction current and partly by bombardment. The shorter and thicker the filament the more important becomes the latter, and finally, reducing the filament to a mere button, all the heating must practically be attributed to the bombardment. So in the experiment before shown the button is rendered incandescent by the rhythmical impact of freely movable small bodies in the bulb. These bodies may be the molecules of the residual gas, particles of dust or lumps torn from the electrode; whatever they are, it is certain that the heating of the button is essentially connected with the pressure of such freely movable particles, or of atomic matter in general, in the bulb. The heating is the more intense the greater the number of impacts per second and the greater the energy of each impact. Yet the button would be heated also if it were connected to a source of a steady potential. In such a case electricity would be carried away from the button by the freely movable carriers or particles flying about, and the quantity of electricity thus carried away might be sufficient to bring the button to incandescence by its passage through the latter. But the bombardment could not be of great importance in such case. For this reason it would require a comparatively very great supply of energy to the button to maintain it at incandescence with a steady potential. The higher the frequency of the electric impulses the more economically can the button be maintained at incandescence. One of the chief reasons why this is so is, I believe, that with impulses of very high frequency there is less exchange of the freely movable carriers around the electrode, and this means that in the bulb the heated matter is better confined to the neighborhood of the button. If a double bulb, as illustrated in Fig. 30, be made, comprising a large globe B and a small one *b*, each containing as usual a filament *f* mounted on a platinum wire *w* and w_1, it is found that if the filaments *f f* be exactly alike it requires less energy to keep the filament in the globe *b* at a certain degree of incandescence than that in the large globe B. This is due to the confinement of the movable particles around the button. In this case it is also ascertained that the filament in the small globe *b*



Showing the Effect of Confining the Gas Around the Electrode.

is less deteriorated when maintained a certain ength of time at incandescence. This is a necessary consequence of the fact that the gas in the small bulb becomes strongly heated and therefore a very good conductor, and less work is then performed on the button, since the bombardment becomes less intense as the conductivity of the gas increases. In this construction, of course, the small bulb becomes very hot, and when it reaches an elevated temperature the convection and radiation on the outside increase. On another occasion I have shown bulbs in which this drawback was largely avoided. In these instances a very small bulb, containing a refractory button, was mounted in a large globe and the space between the walls of both of was highly exhausted. The outer large globe remained comparatively cool in such constructions. When the large globe was on the pump and the vacuum between the walls maintained permanent by the continuous action of the pump, the outer globe would remain quite cold, while the button in the small bulb was kept at incandescence. But when the seal was made, and the button in the small bulb maintained incandescent some length of time, the large globe too would become warmed. From this I conjecture that if vacuous space (as Prof. Dewar finds) cannot convey heat, it is so merely in virtue of our rapid motion through space or, generally speaking, by the motion of the medium relatively to us, for a permanent condition could not be maintained without the medium being constantly renewed. A vacuum cannot, according to all evidence, be permanently maintained around a hot body.

In these constructions, before mentioned, the small bulb inside would, at least in the first stages, prevent all bombardment against the outer large globe. It occurred to me then to ascertain how a metal sieve would behave in this respect, and several bulbs, as illustrated in Fig. 31, were prepared for this purpose. In a globe b was mounted a thin filament f (or button) upon a platinum wire w passing through a glass stem and leading to the outside of the globe. The filament f was surrounded by a metal sieve s. It was found in experiments with such bulbs that a sieve with wide meshes apparently did not in the slightest affect the bombardment against the globe b. When the vacuum was high the shadow of the sieve was clearly proected against the globe and the latter would get hot in a short while. In some bulbs the sieve s was connected to a platinum wire sealed in the glass. When this wire was connected to the other terminal of the induction coil (the E. M. F. being kept low in this case), or to an insulated plate, the bombardment against the outer globe b was diminished. By taking a sieve with fine meshes the bombardment against the globe b was always diminished, but even then if the exhaustion was carried very far, and when the potential of he transformer was very high, the globe b would be bombarded and heated quickly, though no hadow of the sieve was visible owing to the mallness of the meshes. But a glass tube or other continuous body mounted so as to surround he filament did entirely cut off the bombardment, and for a while the outer globe b would emain perfectly cold. Of course when the glass ube was sufficiently heated the bombardment against the outer globe could be noted at once. The experiments with these bulbs seemed to show hat the speeds of the projected molecules or particles must be considerable (though quite inignificant when compared with that of light), otherwise it would be difficult to understand how they could traverse a fine metal sieve without being affected, unless it were found that such small particles or atoms cannot be acted upon directly at measurable distances. In regard to the speed of the projected atoms, Lord Kelvin has recently estimated it at about one kilometre a second or thereabouts in an ordinary Crookes bulb. As the potentials obtainable with a disruptive discharge coil are much higher than with ordinary coils, the speeds must of course be much greater when the bulbs are lighted from such a coil. Assuming the speed to be as high as five kilometres and uniform through the whole trajectory, as it should be in a very highly exhausted vessel, then if the alternate electrifications of the electrode would be of a frequency of five millions, the greatest distance a particle could get away from the electrode would be one millimetre, and if it could be acted upon directly at that distance the exchange of electrode matter or of the atoms would be very slow and there would be practically no bombardment against the bulb. This at least should be so if the action of an electrode upon the atoms of the residual gas would be such as upon electrified bodies which we can perceive. A hot body enclosed in an exhausted bulb produces always atomic bombardment, but a hot body has no definite rhythm, for its molecules perform vibrations of all kinds.

If a bulb containing a button or filament be exhausted as high as it is possible with the greatest care and by the use of the best artifices, it is often observed that the discharge cannot, at first, break through, but after some time, probably in consequence of some changes within the bulb, the discharge finally passes through and the button is rendered incandescent. In fact, it appears that the higher the degree of exhaustion the easier is the incandescence produced. There seems to be no other causes to which the incandescence might be attributed in such case except to the bombardment or similar action of the residual gas, or of particles of matter in general. But if the bulb be exhausted with the greatest care can these play an important part? Assume the vacuum in the bulb to be tolerably perfect, the great interest then centres in the question: Is the medium which pervades all space continuous or atomic? If atomic then the heating of a conducting button or filament in an exhausted vessel might be due largely to ether bombardment, and then the heating of a conductor in general through which currents of high frequency or high potential are passed must be modified by the behavior of such medium; then also the skin effect, the apparent increase of the ohmic resistance, etc., admit, partially at least, of a different explanation.

It is certainly more in accordance with many phenomena observed with high-frequency currents to hold that all space is pervaded with free atoms rather than to assume that it is devoid of these and dark and cold, for so it must be if filled with a continuous medium, since in such there can be neither heat nor light. Is, then, energy transmitted by independent carriers or by the vibration of a continuous medium? This important question is by no means as yet positively answered. But most of the effects which are here considered, especially the light effects, incandescence, or phosphorescence, involve the presence of free atoms and would be impossible without these.

In regard to the incandescence of a refractory button (or filament) in an exhausted receiver, which has been one of the subjects of this investigation, the chief experiences, which may serve as a guide in constructing such bulbs, may be summed up as follows: 1. The button should be as small as possible, spherical, of a smooth or polished surface and of refractory material which withstands evaporation best. 2. The support of the button should be very thin and screened by an aluminum and mica sheet, as I have described on another occasion. 3. The exhaustion of the bulb should be as high as possible. 4. The frequency of the currents should be as high as practicable. 5. The currents should be of a harmonic rise and fall, without sudden interruptions. 6. The heat should be confined to the button by inclosing the same in a small bulb or otherwise. 7. The space between the walls of the small bulb and the outer globe should be highly exhausted.

(To be continued.)

Turpin, the inventor of melinite, has submitted to the French War Office an electric gun alleged to be capable of discharging 25,000 projectiles in five minutes and to have a range of several miles. The apparatus is comparatively light in weight, so that it can be drawn by two horses and worked by four men. The projectiles are small shells charged with a secret chemical preparation, spreading death for sixty yards around. The English Government is said to be negotiating for the purchase of the invention, though skeptical of its value.

Boston Notes.

The project for changing the location of some of the street car tracks in Lynn is arousing more interest in that city of shoes than any other topic. The traveling public are taking the matter in hand and by petitions and enquiries are demonstrating the injustice to the community that must ensue, and especially to the working classes, should the proposed changes be made.

For some time past there have been lively doings in the suburban towns of Reading, Wakefield and Stoneham in connection with a public agitation for the adoption of the Municipal Lighting Act of 1891 entitling towns and cities to purchase or erect and operate their own gas and electric lighting plants. These communities have for some time past been acting independently. Appeals have been made to the State Legislature for power to compel the local lighting company to sell its plant at a fair market price to the town of Wakefield. As yet no such sale has been effected though negotiations still continue in progress. Now, however, the prominent men representing the local boards of trade are trying to formulate a scheme whereby the three towns shall conjointly establish a municipal lighting plant, locating it in Wakefield, the other towns taking their supply from this central station.

Much interest is being taken in the tests that are now being made with the large alternating current motor that has been installed by the Hartford, Conn., Electric Light Company. The motor is of 300 H. P. and is operated by current generated at the Farmington water power station. By this means the city of Hartford is being supplied with power from one of the best water privileges in the State.

There was quite a demonstration a few days ago in the town of North Weymouth, the occasion being the opening for regular traffic of the extension of the Quincy and Boston Electric Street Railway across Weymouth Fore River into the town of that name. The traveling public greatly appreciate the facilities by means of which they can take an electric car in the very centre of Boston and ride out fourteen miles into the shoe manufacturing region. In fact, any one can now travel by electrics from Peabody, some twenty miles north of Boston, passing through the latter city, and fourteen miles south, a direct run of thirty-four miles. Ere many months are over a like feat will be possible from Gloucester, forty miles north to Brockton, twenty-two miles south of Boston, thus making a clear run by electric cars of over sixty miles. The way in which Eastern and Southern Massachusetts is being covered by electric railways is one of the interesting features of electric railway development; still many additional new roads are under construction. There is neither lack of capital nor of enterprise in this section of the country.

The various firms in Boston who make a specialty of wiring and installing electric lights in dwelling houses are enjoying quite a boom, for among the innumerable buildings now being erected in or around this city very few indeed, whether mansions or cottages, but are wired throughout when building for bells and lights.

General News.

What is Going on in the Electrical World.

St. Louis, Mo.—Electric cars have taken the place of horse cars on the Cass avenue line.

Manitou, Col.—The franchise granted to M. A. Leddy has been recalled by the town council.

Columbia, S. C.—Electric motors have been installed in the Penitentiary shops to run the machinery.

Batavia, N. Y.—The taxpayers of this village have voted in favor of the town purchasing an electric lighting plant and operating it. $23,000 will be raised for this purpose.

Milwaukee, Wis.—The Milwaukee and Wauwatosa Railway, now employing steam as a motive power, is to be changed soon to an electric road.

Toledo, Ohio.—The Toledo Electric Company's new plant, which is said to be the finest electric light plant west of New York, is nearly ready to begin work.

Sandusky, Ohio.—The Sandusky, Milan and Norwalk Electric Railway is nearly completed. The new line is practically an extension of the People's Electric Railway of Sandusky.

Washington, D. C.—The Washington and Arlington Electric Railroad Company are having a route surveyed to Mt. Vernon for a proposed electric railway direct from Washington to that place.

Toronto, Can.—It is understood here that the Toronto and Mimico Electric Railway is to pass into the hands of the Toronto Street Railway Company in a few days, and that the cars of the latter will run to the Humber.

Houston, Texas.—The council has granted right of way to the Harrisburg Electric Railroad

Company for a period of twenty-five years. The road to be built by the company will be five miles long, beginning in this city and running to Harrisburg.

Phœnix, Ariz.—The contract for lighting the streets has been awarded to the Phœnix Light and Power Company and the East End Electric Light Company, each company to furnish the same number of lights as the other and of the same power.

Buffalo, N. Y.—If a report current here is to be credited, the Edison General Electric Company will in a few months remove its works from Schenectady to Depew, the new town near this city, being dissatisfied with its site in Schenectady, where the plant is annually liable to damage from floods in the Mohawk River.

Elizabeth, N. J.—The plant of the Electric Light Company, lately totally destroyed by fire, is now almost entirely replaced by new apparatus. In less than forty-eight hours the lights extinguished by the fire were burning again, the company having ordered dynamos, engines, etc., before the flames had subsided.

Salt Lake, Utah.—The suit of D. F. Walker against the Salt Lake and Ogden Gas and Electric Light Company has been withdrawn, the differences between the parties having been amicably settled. The company will at once reconstruct its plant and make extensive improvements both in this city and at Ogden.

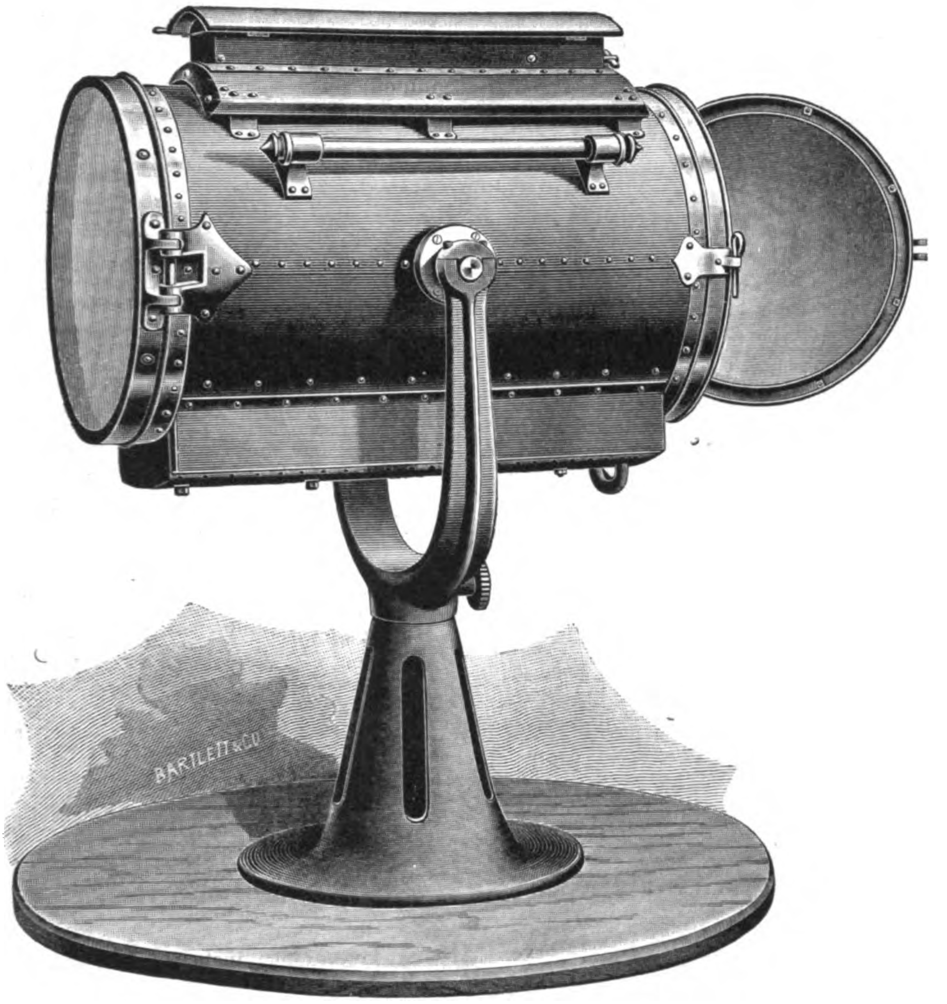
Bridgeton, N. J.—The South Jersey Traction Company has come into possession of all the franchises and property of the Bridgeton and Millville Turnpike Company and the Bridgeton Rapid Transit Company. The Traction Company is building the electric road in Bridgeton and between Bridgeton and Millville.

Roseburg, Ore.—The electric light plant, which has been in the hands of a receiver since last September, has been sold. The Northwest General Electric Company of Portland purchased the real property and part of the plant, consisting of lamps, wires, franchise, etc., and Charles A. Sprandel, of Roseburg, purchased the engine, dynamos and other appliances at the power house.

Davenport, Iowa.—An electrically operated street sprinkler has been introduced here and is doing effective work on the streets in which rails are laid. The car is operated with the greatest ease and can be shot along with any speed desirable and brought to a standstill in a twinkling. It is equipped with a Westinghouse single reduction twenty horse power motor and is fitted with an air brake instead of the ordinary brakes used on the street cars.

Providence, R. I.—The *Journal* states that the Union Railroad Company has let the contract for the overhead wire construction of upwards of seventy miles of track, and the intention is to push this part of the work to completion at the rate of a mile a day, so that the trolley can be put in operation, if unexpected obstacles are not encountered, early in the fall. Then the city will have about fifty miles of trolley, not including the four miles on the Broad street route to Pawtuxet, and the suburban districts will have nearly, if not altogether, twenty miles covered by electric cars.

Hartford, Conn.—The Hartford and West Hartford Horse Railway Company's amended charter has been reported favorably in the Senate. It provides that the company may use any motive power but steam and may use electricity for heat and light. It may sell and distribute electricity in West Hartford, Farmington and Canton. The company is authorized to increase its capital to $1,000,000. It may extend its tracks to Collinsville, New Britain and Plainville and connect at the city line with the Hartford and Wethersfield Horse Railway Company under such terms as the railroad commissioners may prescribe if the two companies cannot agree.



THE NEW WARD PROJECTOR.

The New Ward Projector.

The Electric Construction and Supply Company of New York City, well known for its line of Ward Arc Lamps, has been the pioneer concern in this country to introduce projectors using the Mangin reflecting lens which has acquired a wide reputation abroad but has heretofore been unknown in this country.

A well designed searchlight with a Mangin lens is now being manufactured by this company, and is shown in the illustration on this page. its most important features outside of the lens being the simplicity of its construction and the apparatus by means of which it is manipulated.

The frame is cylindrical and made of polished brass, and is mounted on a standard of the same material. The reflecting lens is mounted in the rear end of the cylinder, shown open in the illustration. The lamp, of the Ward pattern, is mounted in the front of the drum. the case containing the mechanism being placed in front of the carbons, which face the reflector, so that no direct rays from the arc are reflected from the front glass, the light coming entirely from the reflecting lens.

The barrel is arranged to revolve horizontally upon its standard, and can also be tilted vertically through a considerable angle, these two movements being controlled by means of gearing from the pilot house upon which the reflector is mounted.

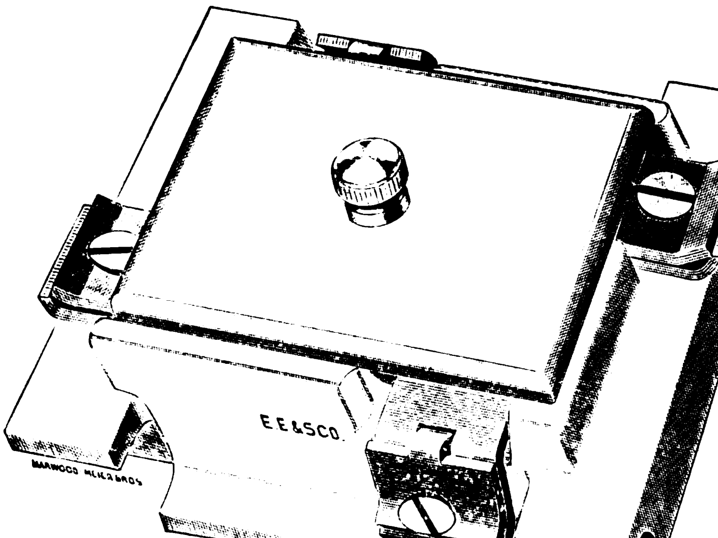
The lamp, which feeds by gravity, is controlled by nicely adjusted mechanism which operates with perfect freedom when the lamp is set at its greatest angle. The lamp is also provided with a horizontal feed along the barrel so that the focus of the carbons can be said to produce a concentrated beam of light or to spread the rays over a greater area if desired. The company has one of these projectors on exhibition in its office, 18 Cortlandt street, N.Y., an inspection of which will verify the claims made for the new instrument. The lenses, which are all made in this country, can be supplied at a great reduction over the imported ones, and the price of the apparatus is therefore but little greater than the old style metal reflectors.

The E. E. and S. Porcelain Covered Branch Block.

Herewith is given a cut of the improved Branch Block manufactured by the Electric Engineering and Supply Company. 308 and 310 West Jefferson street, Syracuse, N.Y.

In order to satisfy the underwriters' requirements and at the same time improve the appearance and add to safety and convenience in use, the E. E. and S. Company have fitted their branch blocks with porcelain covers. They are made of the well-known "Syracuse" porcelain, neatly finished and held in place by a thumb nut. These are readily removed by the fingers, avoiding the necessity of screwdriver or pliers and rendering the block unusually easy of access.

The cover protects the connections from dirt and accumulation of floating particles and in case of a melted fuse retains the metal and prevents possible damage.



THE E. E. AND S. PORCELAIN COVERED BRANCH BLOCK.

The blocks are strong and compactly made, of ample carrying capacity and easily wired, and the main and branch wires are separated by projections from the porcelain base, while both are held away from the ceiling.

These blocks are satisfactory in every respect and endorsed by underwriters and users everywhere.

COMMERCIAL PARAGRAPHS.

The Massachusetts Chemical Company, manufacturers of the well known Insullac, report an increased sale of their material notwithstanding the general depression of business. They have already begun to ship in considerable quantities to European ports, and state that the managers of twelve of the largest street railways in this country have issued orders that no new motors will be accepted by them unless they are insulated with Insullac.

The Ansonia Electric Company report that notwithstanding the long days are here the sale of Stanley Transformers does not seem to decrease in the slightest.

The W. S. Hill Electric Company, ever on the alert to sustain the fine reputation it has gained for electrical apparatus of the highest grade, has just issued one of the handsomest illustrated catalogues that have appeared for some time past in the electrical field. The volume is profusely illustrated with cuts of about every device this company manufactures, each cut being accompanied with descriptive matter and price list for every size in which the devices are made. Several handsome cuts appear of the marble switchboard for 50 circuits recently made for the Narragansett Electric Light Company's station at Providence, R. I., which switchboard is entitled to rank as the most unique and beautiful piece of work of its kind ever manufactured. Every central station manager ought to have a copy of this catalogue.

Since the Elektron Manufacturing Company opened its Boston office at 103 Milk street it has done more than a satisfactory business with its efficient motors for elevator work. A number of good contracts have been secured, and at present Mr. E. Marshall, manager, is installing complete passenger elevators in three large business blocks. In each case a 10 H. P. engine is called for to operate the elevators, and those which have already been installed are giving unbounded satisfaction. Mr. Marshall is an old hand at elevator work; knows just every modern improvement that is required, and is taking care of the Elektron Manufacturing Company's business in good shape.

The new style of porcelain cleat for inside wiring which the Hammond Cleat Company recently placed on the market has met with a prompt and ready demand. The company has received a big pile of orders and is in receipt of many flattering testimonials from those who have used this specialty.

The Consolidated Electric Manufacturing Company, Boston, has this week shipped another of its 60-arc light dynamos, equipped with the Elkins Automatic Regulator, which is proving one of the most efficient and economical devices that have yet been applied to arc dynamos.

So prosperous has the Brown Electric Company of Boston become since its recent organization that it has been decided to double up its capital so as to enable it the better to take care of its rapidly expanding business, and to carry a larger and more complete line of electrical goods.

The Mather Electric Company has just completed the installation of an isolated plant of their system in the nine story building just erected by and for the International Trust Company corner Devonshire and Milk streets, Boston. The plant is of 600 lights capacity, the dynamos used being what is known as the "Kodak," direct coupled with a Westinghouse engine, which together form the most compact and efficient combination now on the market and splendidly adapted where space is limited as in this particular case. This is the first installation of the kind in Boston, and it is naturally exciting a large share of interest.

The Boston Braid Company, which makes a specialty of braiding silk for incandescent lamp filaments, has found it necessary to lease more ample factory room, and has more than doubled its facilities for making its high grade silks, which are now in use everywhere.

Messrs. J. W. Penfield & Co., Willoughby, O., one of the largest manufacturing concerns in the State, will soon place on the market a line of friction clutches especially adapted for use in electrical power plants.

Price List No. 6 has just been issued by the Okonite Company, Limited, from the New York headquarters, 13 Park Row. It is a pamphlet of over fifty pages, containing a fund of valuable information concerning the celebrated product of the company, and should be in the possession of everyone interested in the perfect insulation of telephone, telegraph, electric light and power wires and cables. It calls special attention to three thicknesses of insulation furnished respectively for low, medium and high tension currents. The covers are rich in appearance and elaborately designed and show a lithographed title into which the well-known Okonite trademark enters conspicuously, the whole showing off finely on a gold background. There is also a view of the company's extensive works at Passaic, N. J., and Manchester, England.

The Ansonia Electric Company are now in position to fill any orders with the new Sunbeam lamp at very low prices. Judging from the number of orders they are receiving, the new lamp is even better than the old Sunbeam.

The Ansonia Electric Company report that the demand for Crocker-Wheeler motors was never as large as within the past month, particularly the fan motors. They also report a number of sales of motors for the pumping of organs.

INCORPORATIONS.

The United States Electric Lamplighter Company, Detroit, Mich. Capital stock, $50,000.

The Knickerbocker Electric Light Company of Flatbush, Kings County, N. Y.—to furnish light and power. Capital stock, $30,000. Incorporators: Richard Ficken, Flatbush; Thomas Murtha, New York; Richard Ulman, New York; William E. Martin, Brooklyn; John Murphy, Brooklyn.

The stockholders of the Salt Lake and Ogden (Utah) Electric Light and Gas Company at a recent meeting unanimously decided on an increase issue of $500.000 bonds. The purpose of the increase is to meet the expense of improvements in the gas and electric light plants.

The Cleveland Cross Town Street Railroad Company, Cleveland, O.—to construct and operate street railroads by electricity or other motive power. Capital stock, $10,000. Promoters: S. H. Short, Jotham Potter, L. A. Russell, W. C. Scofield and Geo. F. Scofield.

The Orient Electric Company, Youngstown, Ohio—to manufacture, repair and deal in arc and incandescent electric lamps, electrical machinery, specialties, etc. Promoters: F. Wagland Brown, Linus S. Denison, Clyde O. Shatto, Fred C. Brown and Albert I. Powers.

The Dills Manufacturing Company, Sprague, Wash.—to manufacture and sell an electric lamp hanger. Capital stock, $10,000. Promoters: Elbert Dills, S. E. DeRackin and Leonard F. Williams.

The Suburban Electric Company, Wheeling, W. Va.—to supply light, heat and power by means of electricity in Wheeling and vicinity. Promoters: Geo. W. Woods, J. J. Woods, I. M. Garvin and B. W. Peterson, Wheeling, W. Va.

The Farrall Electric Heat and Light Company, New York, N. Y.—to manufacture, use and sell and grant to others the right to use and sell apparatus for heating and lighting by electricity under U. S. patents of Theophilus Farrall. Capital stock, $1.000,000. Promoters: Henry A. Hubert, New York City; Wm. Albert Rudd, Brooklyn, N.Y.; Wm. E. Baskette, New York City.

The Hornberger Electric Manufacturing Company, Elkhart, Ind.—to manufacture and sell and repair electrical apparatus of all kinds. Capital stock, $20,000. Promoters: Wm. H. Hornberger, Chas. A. Hornberger and John C. Boss, Elkhart, Ind.

The Idaho Electric Railway, Light and Power Company, Weiser, Idaho—to construct an electric railway from Weiser to the Seven Devils. The company is composed of Ohio capitalists and local residents.

The Albert Lea Electric Company, Albert Lea, Minn.—to manufacture and furnish electric light and power, etc. Capital stock, $35,000. Promoters: C. G. Edwards, S. H. Cady, W. E. Todd, Harry Jones and S. S. Edwards, all of Albert Lea.

The McDonald Company, Norfolk, Va.—business: real estate and improvements; water, gas and electric works; securities, etc. Promoters: R. H. McDonald, San Francisco; Wm. A. Wrenn, Norfolk; A. P. Thorn.

The Electric Light, Heat and Power Company of Gettysburg, Pa.—to supply light, heat and power to the public at Gettysburg. Capital stock, $25,000. Promoters: E. M. Hoffer, H. G. Walmer, Harvey B. Hanck.

The Merchants and Manufacturers' Electric Light, Heat and Power Company, Erie, Pa.—to manufacture and supply light, heat and motive and mechanical power by means of electricity in Erie. Capital stock, $50,000. Promoters: E. D. Carter, Edward C. Siegel, John S. Rilling.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JUNE 27, 1893

ELECTRIC RAILWAYS AND APPLIANCES.

500,256. System for Supplying Electricity to Railways. Michael H. Smith, Halifax, England. Filed Oct. 26, 1887.

500,263. Trolley Support. William Duncan, Allegheny, Pa. Filed Dec. 7, 1892.

500,306. Conduit Railway Trolley. Ernest P. Warner, Chicago, Ill., assignor to the Western Electric Company of Illinois. Filed July 30, 1892.

500,375. Trolley. William H. Brodie, Brooklyn, N. Y. Filed March 15, 1893.

500,417. Automatic Disconnector for Trolley Wires. Ray N. Noyes, Haverhill, Mass. Filed Jan. 23, 1893.

500,432. Auxiliary Car Motor. William H. Schallioll, Chester, Pa. Filed Nov. 8, 1892.

500,506. Inclosed Conductor for Electric Railways. John A. K. McGregor, Chicago, Ill., assignor of one-fourth to Homan R. Powers, same place. Filed March 19, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

500,192. Electric Lighting Device. William H. Clewley, Providence, R. I. Filed April 15, 1893.

500,199. Push Button. James S. George, Jr., Philadelphia, Pa. Filed Oct. 20, 1892.

500,200. Push Button Cut-Out. James S. George, Jr., Philadelphia, Pa. Filed Nov. 28, 1892.

500,201. Cut-Out for Electric Lighting Systems. James S. George, Jr., Philadelphia, Pa. Filed Dec. 30, 1892.

500,279. Filament for Incandescent Electric Lamps. John Criggal, Newark, N. J. Filed Oct. 31, 1891.

500,341. Electric Arc Lamp. Wilhelm Mathiesen, Leipsic, Germany. Filed Sept. 5, 1892.

500,357. Electric Lighter. Bernhard Tropp, New York, N. Y., assignor of one-half to George Curtis Wright, same place. Filed Aug. 30, 1892.

500,421. Hanging Device for Electric Arc Lamps. Charles A. Pfluger, Chicago, Ill. Filed Oct. 14, 1892.

500,422. Electric Arc Lamp. Charles A. Pfluger, Chicago, Ill. Filed Oct. 31, 1892

DYNAMOS, MOTORS, ETC.

500,132. Electric Motor and Dynamo-Electric Machine. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Oct. 4, 1892.

500,135. Electric Motor. Charles S. Jones, Chicago, Ill.; Susan H. Jones, executrix of said Charles S. Jones, deceased. Filed April 7, 1890

500,144. Brush-Holder. Sam H. Libby, Lynn, Mass., assignor to the General Electric Company of New York. Filed Jan. 19, 1893.

500,276. Electric Locomotive. Frank M. Stevens, White River Junction, Vt. Filed Feb. 29, 1892.

500,301. Electric Generator and Motor. William Stanley, Jr., and John F. Kelly, Pittsfield, Mass., assignor to the Stanley Laboratory Company, same place. Filed Jan. 9, 1893.

500,400. Dynamo-Electric Machine or Motor. Philip Lange, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed April 28, 1891.

500,403. Dynamo-Electric Machine. Frederick H. Loveridge, Chicago, Ill., assignor to the Standard Electric Company, same place. Filed Oct. 22, 1892.

500,455. Automatic Short Circuit for Constant Current Machines. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Oct. 4, 1892.

500,456. Automatic Circuit Breaker. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Oct. 26, 1892.

BATTERIES.

500,284. Galvanic Battery. Mortimer M. Hayden, New York, N. Y., assignor to the Law Battery Company of New Jersey. Filed April 28, 1892.

500,394. Secondary Battery. Frank King and Edward Clark, London, England. Filed March 16, 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

500,226. Telegraphy. Charles Cuttriss, New York, N. Y. Filed Feb. 21, 1893.

500,481. Magnetic Telephone. Charles S. Forbes, London, England. Filed Oct. 27, 1892.

MEASURING INSTRUMENTS, INDICATORS, ETC.

500,236. Static Voltmeter. Arthur E. Kennelly, Orange, N. J., assignor to Thomas A. Edison, same place. Filed Aug. 6, 1892.

500,264. Galvanometer. Adrian H. Hoyt, Manchester, N. H., assignor to the Whitney Electrical Instrument Company, Saco, Me. Filed Sept. 5, 1892

500,359. Indicator. August Utzinger, Nuremberg, Germany, assignor to Shuckert & Company, same place. Filed Feb. 9, 1893

500,404. Electric Indicator. William B. Luce, Brookline, Mass. Filed Jan. 4, 1892.

500,543. Station Potential-Indicator. Charles F. Scott, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Sept. 28, 1892.

SIGNALS AND SIGNALING APPARATUS.

500,285. Police Signaling Apparatus. William H. Kirnan, Bayonne, N. J., assignor to the Gamewell Fire-Alarm Telegraph Company, New York, N. Y. Filed Dec. 28, 1892.

ELECTRIC HEATERS.

500,272. Electric Heaters. Charles E. Roehl, Chicago, Ill., Sidney Z. Mitchell, Portland, Oreg., and Earl P. Wetmore, Helena, Mont. Filed Dec. 23, 1892.

500,288. Electrical Heater. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car-Heating Company, Wheeling, W. Va. Filed Oct. 1, 1892.

500,520. Electric Heater. Earl P. Wetmore, Helena, Mont., assignor of one-half to Sidney Z. Mitchell, Portland, Oreg. Filed Dec. 23, 1892.

PHONOGRAPHS.

500,280. Phonograph. Thomas A. Edison, Llewellyn Park, N. J. Filed Nov. 21, 1890.

500,281. Phonograph. Thomas A. Edison, Llewellyn Park, N. J. Filed Nov. 21, 1890.

500,282. Phonograph. Thomas A. Edison, Llewellyn Park, N. J. Filed Dec. 3, 1890.

MISCELLANEOUS.

500,172. Electrotherapeutic Device. William R. Washburn, Cedar Rapids, Iowa, assignor of two-thirds to F. S. Washburn and F. E. Washburn, same place. Filed Nov. 11, 1892.

500,178. Lightning-Arresters. Montraville M. Wood, Chicago, Ill. Filed Sept. 22, 1892.

500,229. Electric Cut-Out. Ernst Egger, New York, N. Y., assignor of one-third to Aaron Naumburg, same place. Filed Nov. 8, 1892.

500,248. Fusible Cut-Out. Stephen A. Young and Clarence Alden, Maryville, Mo. Filed April 3, 189[illegible]

500,274. Regulating-Switch for Electric Elevators. Alonzo B. See and Walter L. Tyler, Brooklyn, N. Y. Filed Nov. 12, 1892.

500,362. Resistance-Box. Edward Weston, Newark, N. J. Filed Sept. 10, 1892.

500,423. Double-Pole Switch. Charles A. Pfluger, Chicago, Ill. Filed Dec. 19, 1892.

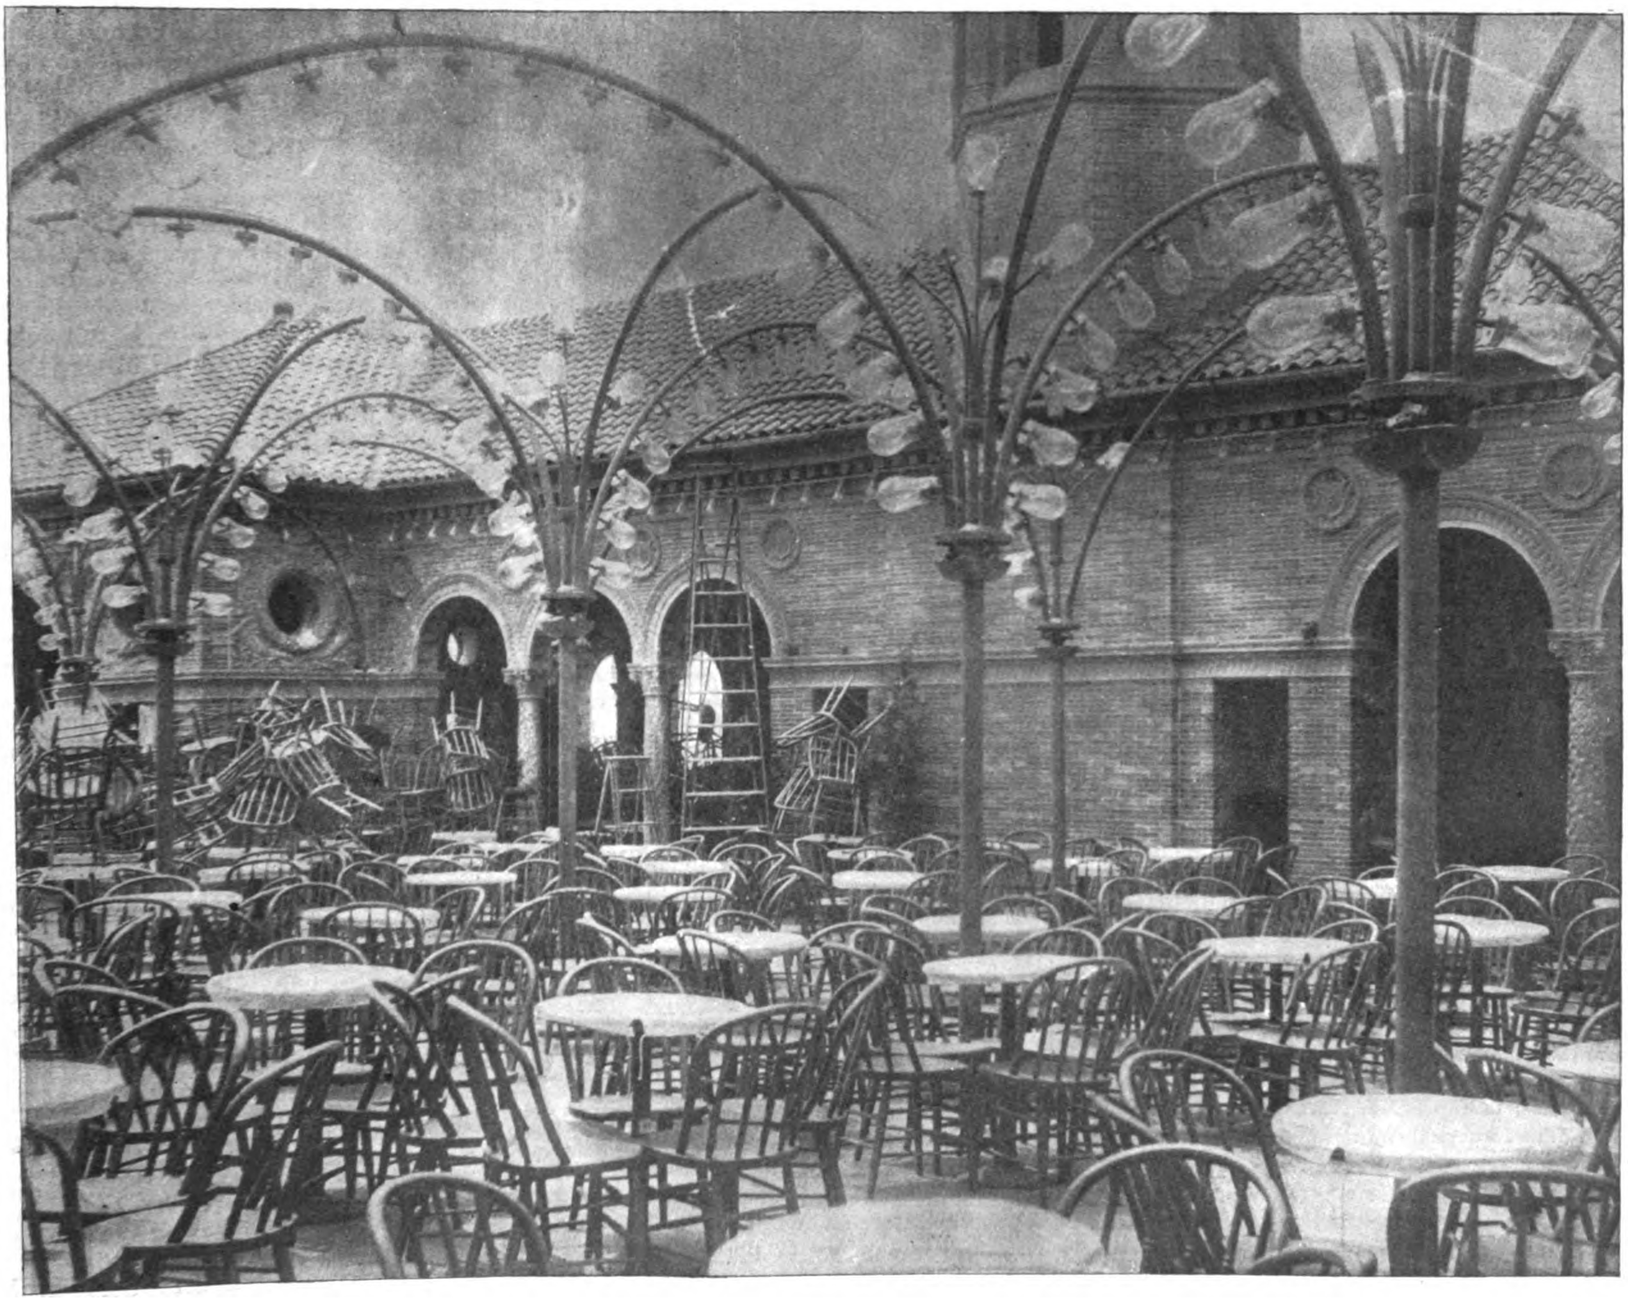
500,454. Lightning-Arrester. William Wurdack, St. Louis, Mo., assignor to the Inter State Complete Electric Construction Company, same place. Filed Sept. 12, 1892.

500,488. Insulating Device for Preventing Electric Currents in Pipes. Simeon D. Gratiaa, St. Louis, Mo., assignor to the Fay Gas Fixture Company, same place. Filed Sept. 1, 1892.

500,539. Electro-Medical Apparatus. Thomas C. Hodgkinson, Melbourne, Victoria, assignor to Henry Thomas Tompsitt, same place, and John Mildred Creed and Edward Henry Bellsario, Sydney, New South Wales. Filed Dec. 24, 1891.

ELECTRICITY.

VOL. IV. NEW YORK. JULY 12, 1893. CHICAGO. No. 26

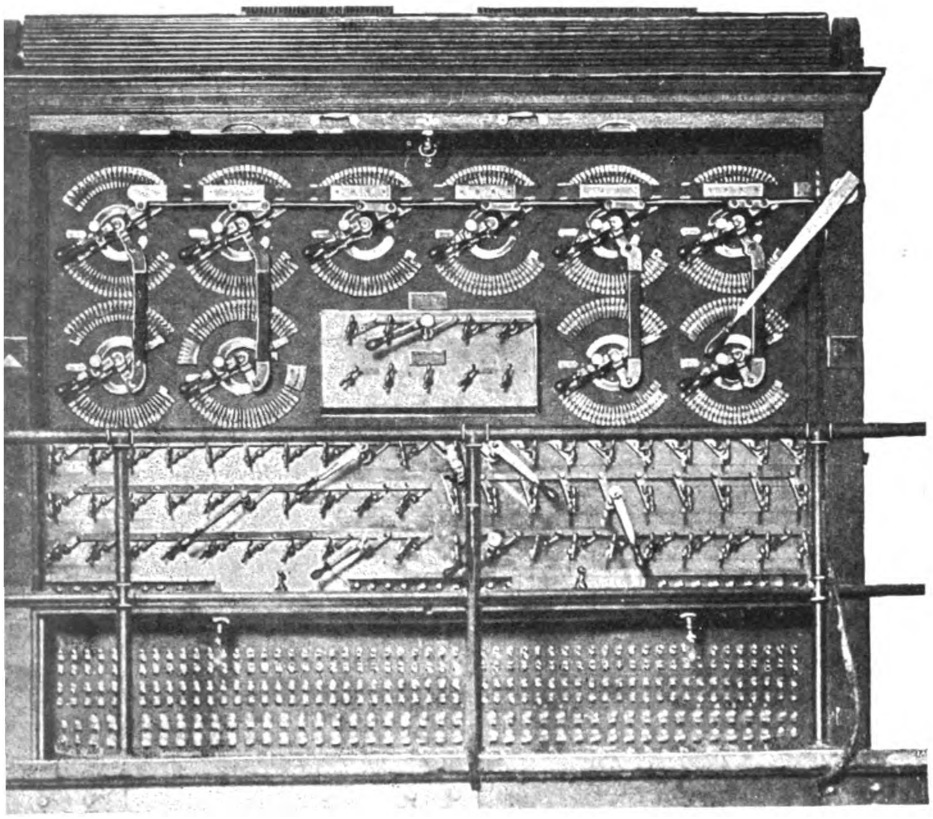


ROOF GARDEN LIGHTING, AMERICAN THEATRE. (SEE PAGE 350.)

nerican Theatre's Electric Plant.

erican Theatre, recently opened in this ins an extensive electric lighting plant designed in accordance with the best ctice in theatre lighting, and special has been given to the distribution of ts for producing every desired stage l to make any accident, such as the of a fuse, practically unnoticeable by g the lights on one circuit at consider- ces apart.

nt consists of three 25 K. W. Edison wound machines of 220 volts, three 45 hines of 125 volts, and one 15 K. W. 220 no for elevator service. The dynamos ven by horizontal high speed Arming- s engines.



STAGE SWITCHBOARD, AMERICAN THEATRE, NEW YORK CITY.

ie dynamo room switchboard independ- rs are run for the following circuits also independent: stage lighting; audi- ighting; front of house; Forty first ilding, Forty-second street building; nue building; Eighth avenue entrance; nd street entrance; roof garden; elec- Eighth avenue building; electric sign, nd street building; working lights in house; stage working lights; dressing

ing is on the three-wire system with wire having a capacity equal to the le wires, and the circuits for different ie building are all brought out to a few oints from which they are controlled.

and auditorium lighting is regulated tage switchboard, shown in Fig. 1. All for lighting in front of the house, in s, entrances, etc., are brought to the e, where the switches and cut-outs are

ge wiring has been given special atten- ially in the separation of the lamps on ch circuit. This is illustrated by the hts, of which there are seventy each of and blue. There are seven three-wire r each color, and the fusing of one side cuit cut-out would only affect the first, twenty-ninth, etc., lamps, and would noticeable to the audience. This same arrangement is carried out in all the stage lighting, and it is almost impossible for any consecutive set of lights to go out from accident.

The switchboard on the stage was manufactured by J. P. Cushing & Company, of Boston, and is the finest one ever made for this purpose. Every gradation of light needed for stage effects is readily made, and the red and white lights can be worked together in the same or opposite directions. The sets of border lights can be graded separately or any sets can be thrown out or graded independently. There are also seventeen sets of floor pockets, wired and regulated in the same way, to use for brackets, lamp posts, hearth fires, or any of the usual stage fittings requiring lights.

Any or all border lights can be thrown entirely out or up to full candle power or to any intermediate point by the simple throw of a switch without regard to their previous arrangement. A switch is also provided to throw the whole plant on to the street service in case of accident in the dynamo room, and every safeguard possible has been provided. The wiring throughout is run in interior conduit and the insulation resistance on the whole plant has been tested to over a megohm.

The entire equipment was put in by the New York Electric Equipment Company and the work was done under the personal supervision of Mr. Noll, General Superintendent of the company.

Electrical Experts.

BY G. EMIL HESSE.

Every important branch of our industries has what is called its experts, and so has electricity—good and bad ones. It certainly has too many of those who actually do not know any more about the theory of electricity than they know about the people on Mars, and that means very little. They use a language here and there intermixed with a few electrical expressions or phrases which to the outside man sound as if they were well posted in the business.

An incident with such an expert came some little time ago within my observation, and the situation would, under other circumstances, have been comical, but the great importance of the question made it serious in this case. It is very seldom that absolutely new things are presented to an expert, but this happened to be the case at this time, and such an incident requires of course a man with a good theoretical and practical education. The telephone is an example of this, and it would be interesting to know just how many of our experts endorsed Professor Bell's theory when first announced. The fact that a half interest in this patent went begging at $10,000 will probably convey a clear idea on that point. Our expert mentioned above would surely not have supported it under any circumstances.

I believe it did not take our friend one minute to decide that the thing in the present case was absolutely useless and not worth a second thought, while the manufacturer who presented it to him on behalf of the inventor and himself, and who was prepared to invest in it if pronounced good, went away satisfied that he had narrowly escaped losing his money and with the firm belief that the inventor in the case was an ordinary everyday schemer, and "the woods are full of those," as the saying goes.

Now this very same thing was afterward taken to two other experts by the inventor, both of them standing at the head of the profession, and the name of one of them especially is almost identical with the science in this country. These two men, seeing the importance of the thing, made separately a thorough examination of it, and returned it in about two weeks' time with the declaration that the theory was perfectly correct and that in practice it undoubtedly would prove a success, and recommended its speedy trial.

What I think therefore would be of value to manufacturers who are not themselves sufficiently posted in electricity is to be very careful in the selection of experts, and if it is an important case and large sums of money are involved, never to rely on the opinion of one man only, but consult men that are known to be sound both in theory and practice.

Never accept an opinion given at the spur of the moment. A new thing has to be studied up and thought over carefully if the opinion is to be of any value.

Better pay a good price for a well considered opinion given by a reliable expert. It is a great and very common mistake to think that money spent on a consulting engineer is money wasted.

It is very natural that new things are most frequently presented in such a new industry as electricity, wherefore it is more important to be on guard in this than in any other science, as a loss may just as well be incurred by investing in a new thing as by refusing to do so.

The Rochester Consolidation.

Mr. Einstein Takes Action to Get What is His.

Mr. Edwin Einstein, a New York capitalist, who was frozen out in the consolidation of the Rochester gas and electric companies some months ago, has brought suit against the companies forming the combine to recover 4,800 shares of Rochester Brush Electric Light Company's stock of the par value of $480,000.

Mr. Einstein alleges that in June, 1891, he purchased the right to use the Brush patents in the county of Monroe of C. M. Rowley, who had purchased them of the parent company; that he transferred the rights to the Rochester Brush Electric Light Company, and it was agreed that he should receive 48 per cent. of the stock of the company and the same proportion of any increase.

When the consolidation was effected the Brush Company retained its corporate name. The consolidated company, however, bought all its stock, giving five shares of consolidated for one of the Brush Company. Mr. Einstein says that there was an increase in the capital stock of just $1,000,000, and not having received his 48 per cent. he now brings suit.

Instrument for Testing Primary Batteries.

An instrument which should prove of great service for testing the condition of a primary cell has been designed by Major Holden, and was exhibited at a *conversazione* of the Royal Society. A small wooden case measuring 3½ inch. by 4½ inch. by 2 inch. deep, contains a dead beat voltmeter reading from 0·5 to 1·5 volts, and a resistance coil. The instrument, which is made by Mr. Pitkin, is shown in Fig. 1 with the outer case removed. The voltmeter *a* is constructed on the principle common to other Holden instruments, and is described in *The Electrician* (London). A club-footed magnet or a horseshoe magnet having one coil is used. The limb within the coil is circular, the outer one being flat, lying against the coil, the end projecting a little. The circular limb carries a small radial pole-piece. A jewelled arbor is mounted as an extension of the axis of the coil, and carries a soft iron radial needle; the end is tipped with brass to prevent magnetic contact. The action of the peculiar magnetic arrangement causes the iron needle to be repelled from the radial pole-piece when a feeble current passes, but when it has moved through an angle of some 10 degs. the other pole of the magnetic system begins to attract it. As a result a fairly uniform scale is obtained. A spring control is employed, which allows the instrument to be held in the hand and used in any position. A resistance coil, *b*, is provided, and a push-button, not shown in the illustration, acting on the spring-contacts, *c*, reduces the resistance from 8 ohms to 2 ohms.

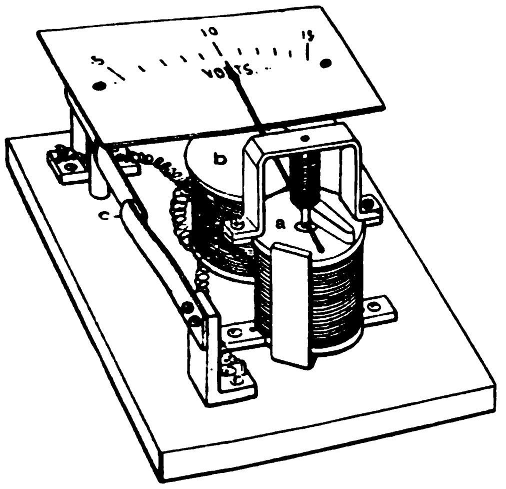


FIG. 1.

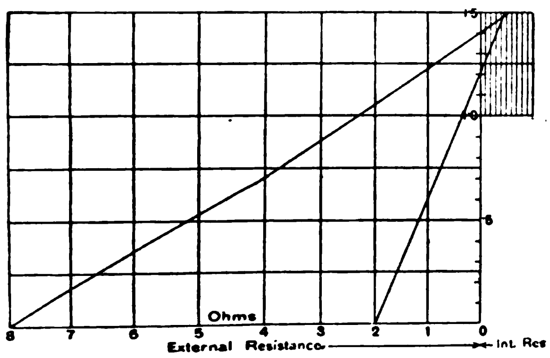

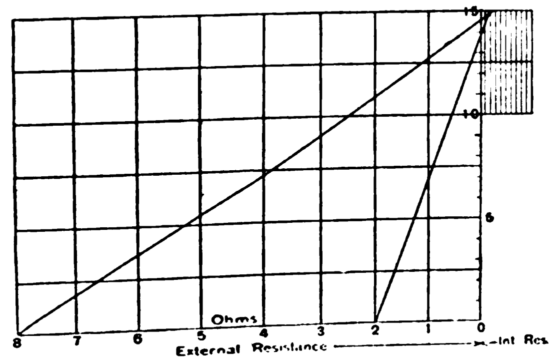

FIG. 2.—DIAGRAM FOR CALCULATING ELECTROMOTIVE FORCE AND INTERNAL RESISTANCE OF LECLANCHE, POROUS POT PATTERN (NEW).

FIG. 3.—DIAGRAM FOR CALCULATING ELECTROMOTIVE FORCE AND INTERNAL RESISTANCE OF E. C. C. DRY CELL, SPECIAL FIRING PATTERN (NEW).

The method of using the instrument is as follows: Two short, thick wires having been connected to the terminals terminating in ends or in a suitable double pointed spear, the ends or spear are put in contact with the poles of the cell it is desired to test: this gives one reading, viz., the difference of potential at the terminals of the cell when it is working through an external resistance of eight ohms (neglecting the resistance of the leads). Then by pressing the push in the side of the case another reading is obtained, this latter being the difference of potential at the terminals when the cell is working through two ohms external resistance; from these two readings (which should be taken as quickly as possible) the electromotive force and internal resistance can be calculated, or their values can be got by reference to a table. The following are the results of a few tests with well-known cells:

—	First reading.	Second reading.	E.M.F.	I. R.
1. Leclanche 6-block agglomerate round pattern (condition, very old)	1.32	1.22	1.35	0.22
2. Leclanche's porous pot pattern, 3-pint size (condition, new)	1.4	1.21	1.47	0.42
3. E. C. C. dry cell, special firing pattern, weight 6.25 lb. (condition, new)	1.43	1.38	1.96	0.15
4. Leclanche Barbier dry cell, No. 1 size (condition, fair)	1.3	1.05	1.43	0.68

The methods of ascertaining the electromotive force and internal resistance of a battery are well known, and possibly the following graphical construction is not new, but is well worthy of attention, being a singularly neat example of graphical calculation. On a piece of squared paper a scale from 0 to 8 is laid down from right to left, and on this is set off the external resistances of the instrument. On the same line, and with the same values of scale divisions, the internal resistance of the battery is to be measured. A vertical scale is chosen to give convenient angles in the construction of the diagram, and on it is set off the volts measured by the instrument. Straight lines are drawn from the 8 and from the 2 on scale of resistances through the readings on the vertical scale and meet at a point on the right-hand side of the zero resistance. The horizontal distance of this point from the zero line gives the internal resistance. The height of this point measured on the vertical scale gives the true electro motive force of the battery. Figs. 2 and 3 relate to the second and third examples already given.

The possible element of error in such a method of testing as that upon which this instrument is based is, of course, that, owing to polarization, the volts of the cell when circuited through the two ohms may be lower than its previous value when circuited through eight ohms, and that both of them will be lower than the volts on open circuit. The error is reduced to a negligible quantity by making the test quickly and by preventing very large currents from passing through the cell; but for the second precaution high resistances are necessary, and these are objectionable because of their great disproportion to the magnitude of the internal resistance which is to be measured.

A Chance for Business.

The town of Madison, Wis., is about to advertise for bids for an arc lighting plant, capacity 200 lights, for the village lighting. It is not intended that the town shall do incandescent lighting.

Germany's Electrical Exhibit at the Exposition.

The Chicago correspondent of the Boston *Herald* gives high praise to the German exhibit at the Fair as a whole, and of its electrical features he has this to say: It is in the Electricity Building, however, that we must learn the lesson of civilization, that there are four nations which to-day are really the great motor forces of the world, the United States of America, Germany, France and England. Other countries are doing practically nothing in the development of this great form of energy, and so in the one department of the Fair that is an absolute new creation since 1876 we find only these four nations, with our own clearly at the head and England as distinctly at the foot of the list. France here occupies more than three times as much space as England, but her exhibit does not equal that of Germany, which has contributions from 30 firms in the electro-technical field, and 43 in mechanics, optics, etc., Berlin, Nuremberg, Cologne, Frankfort and Hamburg being the cities most strongly represented. Then we have the great exhibit of Siemens & Halske of Berlin over in the Machinery Building; we have perhaps already noted the largest direct current dynamo ever constructed, which is 12½ feet in diameter, and is used to furnish light for the German section in that hall, the Terminal Station, the Wooded Island and a good deal more besides. Then we have here three of the biggest search lights ever built, one of them with a 7½ foot projector, throwing sufficient light for a lawn party a distance of 75 miles. This is, perhaps, the "big thing" of the German exhibit in electricity. The German catalogue tells us that the electrical industries of Germany employed 20,000 men and turned out a product valued at $9,000,000. One of the features of this department is the exhibit of telegraph apparatus, complete since 1830, which is made by the German Post-Office Department. Siemens & Halske also have a historical collection of electrical instruments that is very valuable.

Effect of Dynamos on Ships' Compasses.

The Admiralty has directed, says the London *Daily News*, that all ships fitted with 300 and 400 ampere dynamos are to be specially swung for the purpose of ascertaining the effect of the dynamos on the ships' compasses. The effect on all the compasses is to be specially noted, and a report forwarded to the Admiralty. The Lords of the Admiralty have directed that the minimum distance between dynamos and compasses is to be sixty feet in the case of a 300, and seventy feet in the case of a 400 ampere machine, and in the light of the experiments that are now to take place it would be interesting to know the distances between the dynamos and compasses of three of Her Majesty's ships that have recently been damaged by getting into positions at direct variance with the navigators' intentions.

A Subtle Poison.

Apropos of a series of tests making use of gas mains and water pipes for telephone circuits, the London *Lancet* raises a query as to the possibility of electrical lead poisoning. "The small though distinct currents that are set up when the gas and water pipes are connected are attributed to a slow chemical change in the pipes, which may thus represent the plates of a battery. This hypothesis leads one to think of the probable nature of these changes and to wonder whether any effect is produced in the water contained in the water pipes, or whether perchance minute traces of metal as a result of the change would find their way in solution into the water. If the latter event took place another and hitherto unsuspected source of lead poisoning might possibly be traced."

The Milwaukee Lamp Case.

Sensational Affidavits Offered.

A Decision Expected on July 17.

The case of the Edison Electric Light Company et al. vs. the Electric Manufacturing Company et al., on motion for preliminary injunction and on motion to raise the restraining order, came up before Judge Seaman in the United States Circuit Court at Milwaukee on Monday, July 3.

Complainants were represented by R. N. Dyer, Chas. E. Mitchell, Major S. B. Eaton, W. G. Beale and F. P. Fish, and defendants by Messrs. Witter and Kenyon, of New York, and W. H. Webster, of Oconto.

Little new evidence was introduced bearing upon the merits of the incandescent lamp question proper, complainants having rested their case chiefly on an effort to discredit the testimony introduced by the defendants in the Columbia and Beacon cases. Charges of bribery and perjury were numerous, and the proceedings were intensely interesting throughout.

Mr. Dyer, for complainants, made the opening argument, and consumed the greater part of three days. He was followed by Mr. Witter and Mr. Kenyon for defendants, and the argument was closed by Mr. C. E. Mitchell for complainants.

It was attempted by complainants to prove that Goebel lamps marked Exhibits 1, 2 and 3, and also the machines for planing the carbon filaments, had all been made since September, 1892.

Complainants offered in evidence seventeen new affidavits; that of Mr. George F. Barker, which came first, was intended to show the impracticability of the various Goebel lamps, and the inaccuracy of the tests made by Messrs. Pope and Cross. The affidavit of Mr. John W. Howell was in the same direction.

Mr. Clarence A. Seward, of counsel for complainants, who made an able and forcible argument in the Beacon and Columbia cases, made affidavit that to the best of his knowledge and belief a cross-examination of defendants' witnesses would prove the following facts: that as early as 1883, and subsequently in 1887, two lawyers other than Leonard E. Curtis, representing clients opposed to the Edison patents, had investigated the claims of Henry Goebel, and found that he was unable to produce any of his alleged early lamps, and that one of these lawyers had stated that Goebel had no evidence in his possession of having made lamps prior to the date of the Edison patent.

That lamps 1, 2 and 3 were recently and fraudulently made.

That the glass tubing out of which these lamps were made was purchased by Henry Goebel, Jr., on or about Sept. 28, 1892.

That lamp No. 4 was not made by Henry Goebel, but was made after the year 1880 by one Aug. F. Hyer at 468 Grand street, N. Y., as also lamps Nos. 9 and 11.

That Henry Goebel never had or used any incandescent lamps prior to his employment in 1881 by the American Electric Light Company.

That Henry Goebel, prior to 1881, did not employ on his telescope wagon or conveyance any electric lamp, but oil lamps only, and that prior to 1881 Goebel did not have any electric lamp of any kind.

That defendants' witnesses are mistaken as to their dates, and have confused gas light with a white shade with the electric light, and that a large number of these witnesses are ignorant of the construction of electric lamps.

That a large number of these affidavits were procured without any knowledge of the applicants as to their contents.

That prior to 1881 Goebel had never made any carbons for incandescent lamps.

That the machine which Goebel claimed to have made for cutting carbons was not made till after 1881, as also all the other tools for cutting carbons.

Joseph Steiner, an attorney, testified that a majority of defendants' witnesses were poor and ignorant people, living on the east side in New York; that Herman Kraft, who had made affidavit for defendants, was a criminal who had served a sentence for grand larceny, and that Kraft had stated to him, Steiner, that he did not know what his affidavit contained, and had no knowledge of Goebel's alleged electric lamp.

Max Hoffmann, a saloon-keeper, testified that he had seen Henry Goebel, Jr., almost daily since September last, and that the latter said when he heard of Judge Colt's decision at Boston: "That is a nice kind of a Judge; if he had dropped on lamps Nos. 1, 2 and 3, instead of on 4, he would come nearer to hitting the nail on the head. . . . I made those lamps. No. 4 was made in 1883 by a man who worked in my father's shop."

Other affidavits were introduced going to show that Henry Goebel, Jr., had made lamps 1, 2 and 3, that Aug. F. Hyer had made lamp No. 4, and that the machine for planing carbons was made upon the order of Henry Goebel in 1883 at the works of R. Hoe & Company in New York; also throwing discredit upon the affidavits of Henry Goebel, Jr., of Mary Meisinger, Azubah Rice, and Frederick Fitzpatrick, previously introduced at Boston and St. Louis.

Mr. W. H. Meadowcroft had prepared a series of tabulated statements showing that a large majority of defendants' witnesses were friends and relatives of Goebel, which was put in evidence.

The Defense.

Twenty-three new affidavits were offered by the defense, which makes now a total of over 250 affidavits, representing over 200 people in various walks of life, who have been found to testify to the early work of Henry Goebel in incandescent lighting.

In view of the claim of complainants that lamps 1, 2 and 3 were made by Henry Goebel, Jr., in September, 1892, the affidavit of Mr. J. E. Bull was perhaps the most important one introduced in the present case. Mr. Bull, as is well known, has been connected with incandescent lamp litigation since about 1880, chiefly as counsel for the companies which were the predecessors of the present Westinghouse Company.

Mr. Bull's deposition was taken at the Brevoort House, New York, June 2, 1893, just before his departure for Europe. There were present Major S. B. Eaton and D. H. Driscoll for complainants, and Messrs. Witter & Kenyon for defendants. Mr. Bull testified that he first saw lamps Nos. 1, 2, 3 and 4 at the shop of Henry Goebel in Grand street in November, 1890, and that both the Goebels, Henry junior and Henry senior, were present. "The lamps I then saw were either these exhibit lamps or lamps just like them." On returning to his office after that interview he made sketches in his office daybook of these lamps and memoranda as to the occurrence. Copies of these entries were finally offered in evidence as exhibits in this case. A few days before Nov. 15, 1890, Mr. Bull had met, at the factory of the Ball Electric Company in New York, a Mr. Bossard, who had told him of Goebel and his early work; this was the first he (Bull) had heard of Goebel.

Defendants showed by affidavits of Nicholas Finck, Charlotte Finck, C. N. Finck, R. D. Gibby, Baldwin Sebastiani, Lizzie Opry, J. A. Opry, A. D. Kenyon and Henry Goebel, Jr., bribery or attempted bribery of defendants' witnesses to secure alleged evidence of the fraudulent making of Goebel lamps.

Mr. A. D. Kenyon testified that on Feb. 16, 1893, the following statement, embodying what Henry Goebel, Jr., had just related to him in conversation, was placed in writing and signed by Goebel, Jr., in his (Kenyon's) presence:

> I, Henry Goebel, Jr., of the city of New York, hereby certify that this 16th day of February, 1893, I was approached by Max Hofmann, proprietor of the East Side Hofmann House, corner of Seventh street and Avenue A, New York City, and asked what I would take to go on the other side. I said I thought it was worth twenty-five or fifty thousand dollars. He then said to me that he thought he ought to make ten thousand out of it, and that it ought to be worth ten to twenty-five thousand to me to go on the other side, or to get out of the country. He then said he would speak to the other party to-morrow. He asked me if I would take a certified check; I said no, I would only take money. He furthermore said I would get a position for life in the company on the other side. When Hofmann first spoke to me I answered him and carried on the conversation to bring him out. This conversation took place between 3 and 4 o'clock in the afternoon in the saloon in the East Side Hofmann House. Later on, between five and six in the afternoon, I went to the office of Witter & Kenyon, 88 Park Row, and immediately told Alan D. Kenyon about the interview with Mr. Hofmann referred to above.

Complainants' moving papers are embodied in a pamphlet of 50 pages, defendants' answer occupying 486 pages.

We are privately informed that Judge Seaman expects to hand down his decision on Monday, July 17, next.

A Unique News Service.

The Telephone Usurps the Functions of the Ticker and the Newspaper.

Messrs. B. von Harksing, Eugene Godhard and Stephen Godhard, of Buda-Pesth, Hungary, at present enjoying an American tour, are quoted as follows by a Kansas City reporter in regard to the telephonic news service in their city, which was briefly noticed some weeks ago in ELECTRICITY:

"The editor of the *Telephonic Gazette* furnishes all the news of the day to his subscribers by telephone at a rate equivalent to sixty cents a month. The subscribers are given a telephone of a special pattern for which they pay $6. It receives but does not transmit sounds excepting from the central office of the *Telephonic Gazette*. It occupies a space about five inches square and has two ear pieces so that two persons can listen to the sounds on the wire at once. At 9 o'clock in the morning the first edition of the *Gazette* is announced by the simultaneous ringing of a bell in the houses of the subscribers and the business man and his wife listen to the stories of the events of the night. The editor is talking to hundreds of other subscribers at the same time and he has the instrument so arranged that inquisitive housewives must content themselves with his precise statement of the news, and not ask whether the fellow was married or not. He hasn't time, this telephonic editor, to answer all the questions women might ask, or go into all the details of the news. He states it in a laconic way.

"The second edition appears at 10 o'clock, when the foreign news comes over the wire in a condensed form for twenty minutes or less, according to the amount of foreign news on hand. At 11 o'clock the story of the meeting of Parliament is told, along with divers items of a local and political nature. The price of stocks is given and the wise broker may have time to hustle out and get 'long' or 'short' on certain securities in time to save his bank account. At 12 o'clock there is no edition. The editor of the *Telephonic Gazette*, unlike other editors, eats, and he is blessed with that desire about 12 o'clock. At 2 o'clock he begins again, though, and gives a concise statement of the debates in Parliament, telling just which members have been knocked down and giving the story of the resignation of the Ministry, which is reported so often in Hungary that it sticks on the wires. At 3 o'clock the editor in the central office opens up on local news again. He tells about fires, riots and other happenings of the day in Buda-Pesth. He gives his subscribers a chance to rest then until 6 o'clock, when he gives literary news and society news, never giving more than five words to the description of any one woman's gown. Sometimes he repeats the latest poem at 6 o'clock. This 6 o'clock edition is popular with the women and the editor speaks in a soft voice. The 7 o'clock edition is the last. It gives reports of concerts and plays in progress."

Municipal Plants.

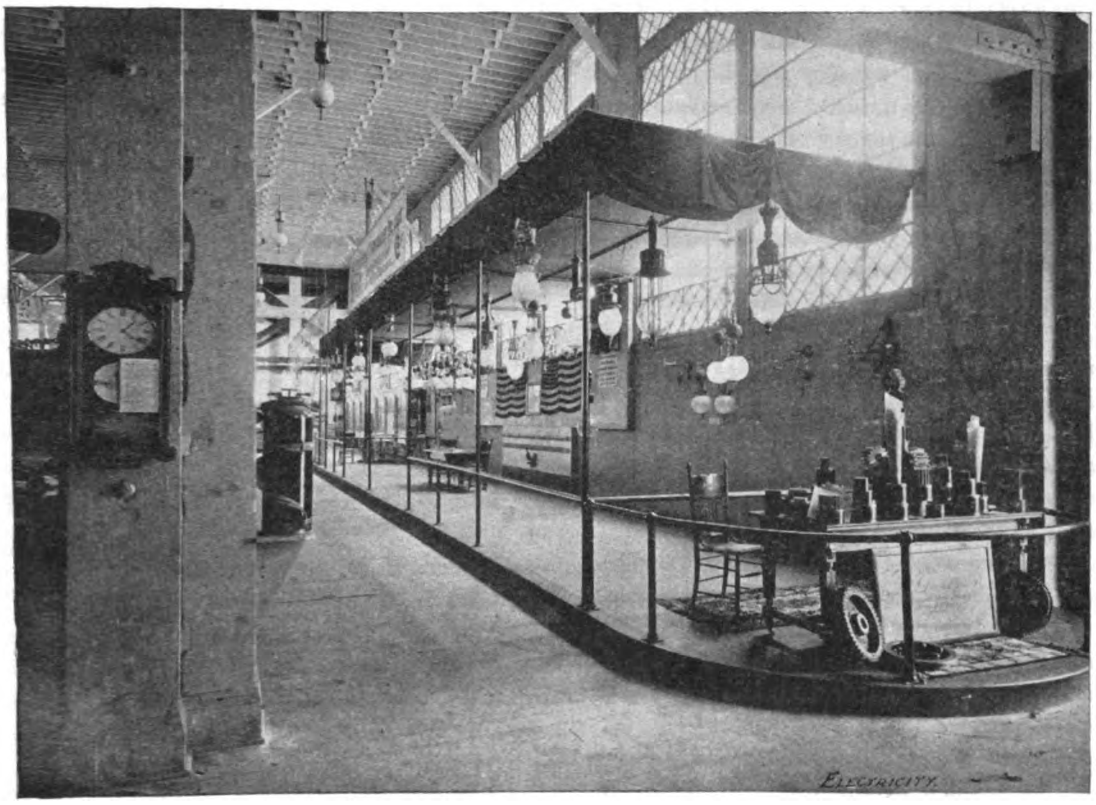
The Detroit *Free Press* has the following words of sound wisdom in regard to municipal electric lighting plants:

"It is no easy task under the most advantageous circumstances for a municipality to do its own work at a less price than the cost by contract. It could not, probably, do its electric lighting at less cost if there were free and open competition in the lighting business. It is only because of the 'combine,' which has forced the price up by excluding competition, that the project of lighting by public account promises better results for the money; and that promise can only be kept by exercising the most careful economy in the purchase of the site and in the establishment and management of the plant. It will be very easy by a lack of judgment or forethought in these matters to make the lighting cost as much under the public system as it did under the exorbitant charges of the contractors; and in that event the people will be greatly disappointed, and have the right to be."

World's Fair Notes.

In the exhibit of the General Incandescent Arc Light Company at the World's Fair, which is illustrated in this issue, is shown one of the most comprehensive displays of arc lamps for incandescent circuits that can be found on the grounds. The list includes not only the ordinary arc lamps, but also the standard, the ornamental, the railway, the series, the chain and the bijou, all of which are manufactured by this company.

The space allotted to the company is located near the northeast corner of the Electricity Building and has been very handsomely draped and decorated. Sixty lamps have been hung from the temporary ceiling and each lamp has been wired up to be turned on or off from a row of switches located on the wall behind the desk. A portion of the exhibit which is attracting considerable attention is the 6-light combination which occupies the central position of the booth. It consists of six arc lights arranged similarly to the ordinary chandeliers, but is much more handsomely decorated with brass finishings.



GENERAL INCANDESCENT ARC LIGHT COMPANY'S WORLD'S FAIR EXHIBIT.

The company have also installed 160 railway lamps in the annex to the Machinery Hall, which are run on the 500 volt circuit, to the entire satisfaction of the exhibitors in that portion of the building. The booth is in charge of C. A. Noll, of New York.

The construction department of the Exposition is to be criticised for the dangerous way in which they have left a number of the switch and fuse boxes exposed in several of the buildings. The boxes in which the wires carrying both high and low tension currents are run are set in the wall very near the floor and can be easily touched by any one standing near them. In view of the fact that the authorities have expended large sums of money in burying the conductors for the protection of the public, it would seem that a few dollars expended for covers for the boxes would be a good investment.

Unique features of the Japanese exhibit in the Electricity Building at the World's Fair are the electroliers and other fixtures. Instead of making them out of brass or other metal they are made out of bamboo. The electroliers are made to hold from one to six lamps and are very substantial and neat in design.

The Deadly Cable.

It Plays Havoc in Broadway.

Cars at a Standstill for Three Hours.

At the hour when Broadway was most crowded with loaded vehicles and busy pedestrians yesterday afternoon, says the *Sun* of July 6, one of the new cable cars of the Broadway surface line was run away with. It sped three-quarters of a mile, from Worth street to Trinity Church, before it stopped. Trucks were brushed aside and upset, horses were thrown from their feet and dragged for blocks under the wheels, four other cars were jammed into a heap in front of the runaway car, and several persons were more or less seriously injured.

During a temporary blockade, car 77, bound down, had stopped at Spring street and the gripman of course left the grip open until the cable was moving again. When he heard the wheels begin to murmur he gripped the cable and started toward the Battery. All went well until the conductor rang for him to stop at Worth street. Then he discovered that he could not open the grip and of course could not put on his brake. He tugged at the wheels in front of him with all his might, but they would not budge either way. The car kept on at full speed, and the conductor rang again to stop, but the cable did not stop, and neither did the car. It went tearing down Broadway until it had come up with five more cars, which were all compelled perforce to join in the procession.

When car 77 reached Old Trinity the cable stopped.

The Philadelphia *Times* has a writer on its editorial staff who seems to have "caught on" to the possibilities of the electric car. He says: "The electric railway is now the method of transit that is in the closest touch with the people. It is the cheapest of all motors; it requires no grading of road-beds; it can climb the highest hills with ease and descend them with complete control of speed, and it goes into the by-ways where the steam line can never penetrate. It is, in fact, the railway of the people, and as such it should be liberally encouraged. It will soon bring every rural community into close relations with the city, and open the most heartsome of rural lands into use for suburban homes."

Legal Notes.

The bondholders of the Electric Light Works of the city of St. Charles, Mo., are taking steps to bring suit against the city in the United States courts for the unpaid interest coupons on the electric light bonds. The special tax for the purpose of having this interest was refused by the authorities last January. The refusal to collect the tax was based upon a decision of the State Supreme Court declaring that cities of the third class could not levy and collect special taxes over 50 cents on the $100 valuation. It is believed the suit, if brought, will be submitted to the court on an agreed statement of facts.

Judge Livingston has granted a preliminary injunction restraining the Lancaster and Columbia Electric Railway Company and the Lancaster Traction Company from laying their railway tracks over a Pennsylvania Railroad bridge at Mountville.

Judge Lea of the Pulaski (Ark.) Circuit Court will render a decision the present week in certain suits involving the validity of $270,000 indebtedness of the City Electric Street Railway Company of Little Rock. The test suits were brought by the Banks of Manistee and Grand Rapids, Mich., and Paris, Ill., and involve the sum of $35,000. A decision in these cases will settle all.

The American Bell Telephone Company has brought suit in the U. S. Circuit Court against two Chicago firms—Wm. Hubbard & Co. and the Cushman Telephone Company—for infringement of patents. The bills of complaint state that the defendants since March 7, 1893, have been unlawfully making and furnishing for use telephones which embody the inventions still controlled under patents not yet expired and owned by the American Bell Telephone Company.

Chancellor McGill of New Jersey has granted a temporary injunction stopping work on the Asbury Park and Belmar Electric Street Railroad. Argument on the application to make the injunction permanent will be heard July 18.

The Colorado Telephone Company won a case in the United States Circuit Court at Denver a few days ago in which it was defendant. Frank G. Browning brought suit for $5,000 for infringement of patent on fire clay conduits for underground wires. The patentee was A. L. Lynch, who had sold the rights to Browning. Judge Hallett decided there was no infringement. Browning appealed.

Current Items.

A Rochester man has devised a plan by which a trolley street car can be stopped almost instantaneously, or within a space of three feet, while the car is going at full speed. His device is operated by a lever in the motorman's cab. It is, generally speaking, a steel shoe, upon which the rear wheels of the car ride, the under side of which is corrugated so as to produce great friction upon the rails of the track. On the top of the shoe is an arrangement which, as soon as the wheel rises upon the shoe, clamps the outer rim of the wheel and at the same time grasps the inner edge of the rail. The simple weight of the car crowds down the shoe upon the rail and at the same time clamps together, as in a vise, the wheel and the rail; and all this by a single movement on the part of the motorman.

Telephonemeter is the new word naming an instrument to register the time of each conversation at the telephone from the time of ringing up the exchange to the ringing off signal. Such a system would reduce rentals of telephones to a scale according to the service, instead of a fixed charge to a business firm or occasional user alike. The instrument has been constructed at the invitation of the German telephone department, and is to control the duration of telephone conversations and to total the time.

ELECTRICITY.

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

The Earth Return.

The trouble between the telephone and electric railway interests in London, mentioned some time ago in ELECTRICITY, is referred to again by our London correspondent this week. Since the petition from the telephone companies was presented to the Board of Trade asking that the specification to prohibit the use of grounded railway circuits be included in the provisions for any future roads, a joint committee of Lords and Commons has started an inquiry in regard to the matter, and has taken the testimony of many of the leading electricians in England.

In view of the trouble that has been found in different places due to ground circuits, not only in the case of telephone and telegraph wires, but to the electrolytic action on buried pipes, it seems at present as if the most satisfactory course would be to provide metallic returns for all circuits, as in that case incidental grounds, which are almost inevitable on railway lines, would not have any noticeable effect on neighboring lines, and this would also obviate the difficulties which have occurred in connection with gas and water pipes.

The greatest advantage which would be secured in the case of insulated railway conductors would be the possibility which would be offered for using much higher voltages than are now practicable. Five hundred volts has been adopted as a standard only because it is considered a safe limit on bare wires, and the early attempts in railway work were made on 220 volts or less.

The testimony of Lord Kelvin in this connection is significant, as he says that there would be no practical difficulty in having return conductors, which if insulated would allow a much higher working pressure and decrease the amount of copper correspondingly.

The right of using the ground return is generally conceded in this country, but it is not improbable that the railways may eventually find it to their own advantage to insulate their return circuits and take advantage of the saving in copper which would result from high voltages.

* * *

THE *Review of Reviews* for July contains an extended sketch of the career of Mr. Thomas A. Edison from the pen of Charles D. Lanier, illustrated with new photographs which are interesting. The article is followed by a sketch of Lord Kelvin, the two being printed under a common heading, "Two Giants of the Electric Age."

It has for about fifteen years been Mr. Edison's chief misfortune that newspaper men fail to maintain their mental equilibrium when writing of him, and Mr. Lanier is no exception.

A correct estimate of Mr. Edison and his work has never yet been printed, and is not likely to be for many years to come. Somewhere, however, between the unfavorable picture drawn by his severest critics and the abnormal figure which exuberant reporters have painted stands the true Edison—a genius, a hard worker, and a public benefactor, but neither a god nor a monstrosity.

Mr. Lanier has quoted Mr. Edward H. Johnson, to whom Mr. Edison owes more than to any other *man* for the success of his various enterprises, and from Mr. Johnson we have about the only prosaic common sense in the article, if we except the following sentence from the author's own pen: "Electrical science is in its infancy."

* * *

An Expensive Lesson.

While the disturbances in the financial and business world this summer have not been as sensational in their nature as were the panics of 1873 and 1884, they have been fully as serious, and it will take a much longer period for a full recovery to take place.

In both of the instances referred to it was only a few weeks until values had recovered to a healthy basis and confidence was fully restored. Then, as now, Wall Street was the first to see the dangers ahead, and had practically recovered from the shock, while yet business disasters were multiplying throughout the country. We predict, however, that in the present instance Wall Street will wait a good deal longer for a boom than it has ever waited before, because the lambs have not been sheared only, they have actually been skinned.

While the Industrial stocks cannot be charged with creating the present condition of affairs, they and their promoters can be honestly charged with the wholesale robbery of the investing public. Other values have shrunk, and will again recover, but the Trust stocks will never recover, because the values never existed, and the people have been fully convinced of the fact.

The London stock markets had their period of Industrial speculation some years ago, and it ended with even more disastrous results than have been felt here. The boom lasted longer, and prices had reached even a more inflated point. Laws were speedily enacted there rendering a repetition of the schemes impossible on any large scale.

It is unfortunate that American investors could not have heeded the impressive lesson, but they did not. They were carried away by the rapid rise of Trust stocks in the market, believing that the rise represented an honest increase in value when it was nothing less than a conspiracy to defraud, engineered by the Trust themselves, and carried out by their official brokers, who sold the stocks back and forth among themselves, reaping fortunes in commissions alone. Thus the public were caught, and the public has paid the bill. Expert Wall Street judgment is that not one in twenty of the organizers of these Trusts has kept his stock on the decline. They have all unloaded enough to leave them with a handsome balance to the good, and whatever stock they have left has cost them practically nothing. It should be noted that in the case of General Electric, with which our readers have most concern, the original Thomson-Houston stockholders could sell their General Electric stock at 75 and still make a substantial profit.

The following table shows approximately the losses which the investing public has sustained through their child-like faith in Trust stocks. Present quotations are all lower (July 7) than when the table was compiled, and some of the companies have made further issues of stock since the date of the highest quotation :

Companies.	Highest since Jan. 1892.		Present quot'ns.	Loss in points.	Amount of capital.	Losses in money.

						$100,811,538

Other stocks listed on Exchange have fallen in price, but they will all recover with an easier money market and a restoration of confidence in the future. But not so with the Trust stocks. They will all settle still further, as one by one their actual condition becomes known.

The public has paid a high price for its folly, and the Trust promoters have grown rich.

* * *

Business Is Not Always Business. It is to be hoped that some way will be found by which the builders of the electric road around the Gettysburg battlefield may be compelled to abandon their project, and make good as far as possible the damage already done.

It is extremely doubtful if the road would ever pay, if built; but, however that may be, the road has no right to be there.

Of course the only objection which can be offered is founded on sentiment; but that objection in this case is overwhelming. The whole scheme of the world's civilization is built up on sentiment, and the battlefield of Gettysburg covers the bones of thousands of brave men who gave up their lives there thirty years ago for sentiment or principles vitalized by sentiment.

The ground is sacred, and to build a road over it, or anywhere near it, is not business, but outrageous vandalism.

* * *

THE Mount Vernon *Chronicle* is sound in its contention that the new Westchester Electric Railroad Company, which obtained a franchise to use electricity, should not now be permitted to use horses. The *Chronicle* closes a strong editorial on the subject as follows : "We have been promised electricity, we want the electricity, and we want it without further delay."

* * *

THE best likeness of Henry Goebel which we have yet seen is the lithograph sent out by the Columbia Lamp Company of St. Louis.

The Prophecy Fulfilled. When ELECTRICITY a few weeks ago stated, upon what we knew to be unquestioned authority, that the Brush Company of Cleveland was to be laid as completely on the shelf as was the Excelsior Company, our statement was met with a chorus of denials from those who either knew nothing about the matter or wished to deceive the public as long as possible.

We have now to report, upon equally good authority, that the order has been actually promulgated; that all the selling offices of the Brush Company are to be closed, and that hereafter whatever Brush apparatus is sold will be sold by the General Electric Company's own offices, and will only be sold when customers insist on having it.

In other words, the Brush Company as a factor in the electric lighting business is dead and buried.

The Boston wreckers have succeeded after many years in their original intention so far as the Brush Company is concerned.

How long they will be able to continue their disgraceful career, and how many magnificent enterprises must still fall before them, are questions worth considering.

* * *

Will the Fort Wayne Co. be the Next? The placing of the Brush Company in a position where it can do no further harm to the Boston squeezers leaves the Fort Wayne Company alone of all the companies controlled by the Trust with any power to be of service to the electrical business generally, the only one which can seriously interfere with Mr. Coffin's plan to establish a dictatorship over the industry in this country.

The Fort Wayne Company is not dead. Its apparatus has always been regarded as efficient and satisfactory; it has attached to it some of the best technical minds in the country, notably Messrs. Wood and Bradley; and greatest of all, it has in Mr. R. T. McDonald a man who has few equals and no superiors as an organizer and promoter. Through Mr. McDonald's efforts, and because of his personal popularity, the company has been able to maintain, under very discouraging circumstances, an able corps of hustlers in its various branch offices. It will be seen, therefore, that this company is well prepared to do business independently. The only drawback is the iron hand of the Master at 44 Broad street, who so far has pulled the strings on Mr. McDonald whenever he saw fit, and Mr. McDonald has in turn been compelled to call his agents off from many a good contract, until 50 per cent. of the business which would come to the Fort Wayne Company if it were working independently has been diverted to other channels.

Mr. McDonald's position has been anything but an enviable one. Were it not that he had made a record for himself, he would be ridiculous in the eyes of business men. He has been for some time, as far as actual power goes, about on a par with Lieutenant Samuel Dana Greene. In brief, he has received his orders, and has been merely the medium for the transmission of orders to those who are supposed to be his subordinates but who in the eyes of Mr. Coffin are his equals in authority.

There have been for the past year signs of restiveness among the Fort Wayne people. The agents have been compelled to submit to a series of grievances the like of which broke the back of the Brush Company early in the game. Nothing, as we have said, but their personal attachment to Mr. McDonald has kept them from scattering to the four winds.

The technical men of the company have been busy with new apparatus, and it is understood that they have now ready to place on the market a new alternating system, an incandescent machine, and a railway generator.

Under present conditions, they might better have saved their time, as none of these machines, whatever Mr. McDonald may desire, will be allowed to achieve prominence in the field. It is possible, however, that a new deal is at hand.

The position of the Fort Wayne Company, it will be seen, is a very remarkable one. Whatever the company may have had to gain at one time from a consolidation, it has nothing further to gain, but can only lose steadily in business and in reputation until it finally goes the way of the other absorbed companies.

That Mr. McDonald will submit, however, to the kind of treatment he has been receiving seems impossible. He is universally recognized, among those who have followed his career closely, as being head and shoulders above Mr. Coffin as a business man, and it is not likely that he will continue for long to be snubbed and set aside. He is a wealthy man, and were it not for one thing we should look for him to sell out his holdings and retire from this business, seeking new fields for his capital and brains. That one thing is the sense of obligation which he is known to feel toward the agents who have stood loyally by him and toward the unprotected stockholders of his company. These agents and these stockholders naturally look to Mr. McDonald to save the company from wreck, and unless ELECTRICITY has over-estimated the man, they will not be disappointed.

* * *

WE HAVE in contemplation a biographical sketch of Mr. E. I. Garfield, which will occupy when published about twelve pages of ELECTRICITY. The city records of the city of Detroit will be quoted from in extenso. We are well aware that Mr. Garfield does not amount to much, but it will some day be of historic interest for the public to know just what kind of men were relied on to make an Electric Trust successful.

* * *

AN ITEM is going the rounds of the country dailies to the effect that Mr. Edison is perfecting a plan to kill all the mosquitoes in New Jersey by electricity. We do not doubt that Mr. Edison, in common with all other residents of New Jersey, would be glad to have mosquitoes abolished or annihilated, but we do not think this item is correct.

* * *

DURING the summer months ELECTRICITY will go to press on Saturday, instead of on Monday as heretofore. Copy and changes for advertisements should therefore reach us not later than Friday.

* * *

The Board of Directors of the General Electric Company is mainly composed of men who have always maintained the good opinions of their business associates. They have been generally supposed to have some regard for the proprieties of life. We doubt, therefore, if they have been made aware of the record of the secretary of the company, Mr. E. I. Garfield. When they are conversant with the facts, they will no doubt call upon him to retire at once.

* * *

The employees of the General Electric Company throughout the country, who have been made aware of a general cut in salaries of from 25 to 33⅓ per cent., are unable to discover any evidence in this of the remarkable prosperity of the company.

* * *

"Mr. Perry is one of the most correct and forcible writers connected with the technical press of the country."—*Western Electrician.*

This may be the language of the Chicago Browning Club and the Dante Society, but it is not English.

General Electric.

(*Boston Commercial Bulletin.*)

Information comes from Providence which reports that the General Electric Company is in the market there as a borrower of money. A prominent banker of that city, who had much to do with electrical companies before the consolidation of the Thomson-Houston and Edison Companies, is said to be very bearish on General Electric. We also hear that the Rhode Island Hospital Trust Company purchased some time ago, before the present financial disturbances became so great, $1,000,000 of the bonds of the Electric Corporation.

This company, it will be remembered, was formed by Mr. Coffin and his associates to finance street railways, etc. In other words, the General Electric Company supplies the machinery and apparatus, etc., and the stocks and bonds which it receives in payment therefor are in turn turned over to the Electric Corporation for cash. In fact, the Electric Corporation is practically a scheme to keep the General Electric Company supplied with cash, for its chief function will be to pay cash for the securities which the parent concern turns over to it.

If memory is correct, an instalment on the subscription to the Electric Corporation securities comes due the 20th of July. This payment will give the General Electric about $1,000,000 in cash.

Queer Prosperity.

(*From the Wall Street News.*)

As an evidence of success (?) the General Electric Company announces that reductions are being made in its salary list, and that a saving has already been made in this item during the past two months of nearly $200,000. This news is given out as a bull tip, and like the sale of the company's gilt-edged treasury stocks recently, the public is asked to believe that this indicates prosperity. Our experience with corporations of this character justifies the belief that this action signifies exactly the reverse. When salaries are cut down and forced economies introduced, it is generally a sign that "the boot pinches" somewhere. When companies are, as this one claims to be, rushed with work to the fullest extent, they don't generally cut down salaries: and when you find they are doing so it is generally good business judgment to let somebody else buy and carry your stock.

Where the Trouble Lies.

"The keynote of the whole situation," says an expert accountant in the *Commercial Bulletin*, "is over-capitalization by industrial corporations and the neglect to provide sufficient working capital; and," he says, "I wish this were the worst that could be said of scores of these Industrials and other stock corporations, but it is not. Many absolutely make a practice of submitting false balance sheets at the end of the year, so false that a stockholder or outsider can know nothing about the real condition of the company. As an illustration of this, I know, and if it should become necessary, I can give the name of one of the largest companies of this country which issued a false balance sheet some time ago."

The "Earth" Question.

An Important Inquiry.

(*From our Regular Correspondent.*)

In consideration of the expected advance in the development of electric traction in England there was recently appointed a joint committee of Lords and Commons to consider and report whether the grant of statutory powers to use electricity ought to be qualified by any prohibition or restriction as to earth return circuits, or by any provision as to leakage induction.

The committee commenced sitting on June 19, and is being watched and its decision awaited with general interest. Parliamentary debates have taken place in recent years as to the protection of telephonic lines from electrical disturbance, and it is unnecessary to dwell on the form or the effect of the various clauses which Parliament has from time to time inserted in the provisional orders of promoters seeking powers for electric traction. The more immediate matter is the decision of Mr. Justice Kekewich in the beginning of February last in the case of The National Telephone Company vs. Graff Baker. In that case the plaintiff, a limited company carrying on the business of supplying telephonic communication under a license from the Postmaster-General, sought relief against the defendant, Mr. Graff Baker, who was the lessee of a tramway line at Leeds, constructed by the Corporation of that city under the authority of a provisional order of the Board of Trade and worked on the trolley system, on the ground that the leakage incident to that system created a serious disturbance in their circuits. Mr. Justice Kekewich held that the disturbance complained of existed, and that it amounted in law to an actionable nuisance, but that, as the corporation of Leeds had statutory powers to work their tramway by electricity, Parliament had legalized it by anticipation. Thereupon the telephone company applied to the Board of Trade to insert a proper protective clause in all provisional orders settled by that department, and after some delay the matter was referred to the joint committee which has just commenced sitting. The clause which the National Telephone Company desire the committee to adopt is that, "in the event of any tramway being worked by electricity otherwise than by electrical power, the persons working it shall be bound so to construct and work their lines as to prevent any injurious interference with the electric circuits from time to time used or intended to be used by the telephone company." The telephone company is, however, to take reasonable and proper precautions in the erection of future circuits, and not to place them in needless proximity to the tramway lines or works, and disputes are to be referred to the arbitrament of the Board of Trade. Several of the railway companies, which allege that they also are prejudicially though differently affected by electric traction, have joined hands with the National Telephone Company in this case.

The present inquiry is said to be the most important one relating to electrical matters that has been held since the electric light inquiry of 1888. In the course of evidence Sir Courtenay Boyle on behalf of the Board of Trade explained the relative positions of the telephone and traction companies. Wm. W. H. Preece was the first technical witness, and the gist of his evidence was as follows: The first telephone fixed in London was operated on a metallic circuit, and ever since the Post Office had used the metallic return. The effect of leakage and induction from the City and South London Railway was most evident on the Post Office telegraph circuits. Whenever a train was started leakage currents had been noticed as far away as North Walsham, in Norfolk. He considered that if London were perforated with electric railways the matter of leakage would become serious. With proper supervision, however, he thought it possible for every tramway in England to use the earth accidentally without doing harm.

Mr. Gaine (manager of the telephone company) gave numerous details as to the number of messages and the cost in various towns of the National Telephone Company's system. The National Company had spent large sums in adopting the metallic circuit in London; the return wire, he considered, was absolutely valueless to the company commercially. Taking Liverpool as an instance, it would cost £20,000 for a switchboard alone, and assuming that electric traction were adopted throughout the country without using a metallic return it would cost the National Company £2,000,000 to protect their system. The company had already spent £100,000 in the London district in changing from the earth to the metallic system. The witness admitted that the Postmaster-General had said that he would give no more licenses to telephone companies unless they used the metallic return. In his estimation a complete metallic circuit system in London would cost £250,000, and it would take five or six years to arrange it.

Dr. John Hopkinson spoke of the disturbance caused to the telephone system at Leeds by the electric tramway. From what we have heard we should imagine this witness stands alone in his experience of the London telephone service when he remarks that there is no disturbance. He considered that only slight complications would be added if tramway companies were obliged to use two conductors.

Lord Kelvin was the next witness, and he said there would be no practical difficulty in having return conductors in either an overhead or an underground system. Two insulated conductors would allow of a much higher working pressure, and would very much diminish the quantity of metal used in the conductors.

Mr. W. E. Langdon (superintendent of the electrical department of the Midland Railway) said that the block signals of the railway he represented had been very seriously affected to a distance of between three and four miles from where the electric tramway crossed the line. There were thirty-two towns on the line where power had been granted for electrical tramways. He recommended the disassociation of those high currents from the earth entirely.

Mr. C. E. Spagnoletti (past president of the Institution of Electrical Engineers, and who had been for thirty-seven years chief engineer of the Great Western Railway,) gave like testimony regarding the disturbance caused by the tramway currents.

Further lengthy evidence was given by Mr. James Swinburne, Mr. R. E. B. Crompton, Mr. A. R. Bennett, Mr. Alexander Siemens, Mr. J. H. Greathead (of the City and South London and the Liverpool Overhead Railways), Mr. J. F. Parsons, Mr. Sellon, Major-General Webber. Evidence was also called on behalf of the Corporations of England and Scotland.

Although the committee had now been sitting for five days, there remained a number of witnesses to be examined. A. B.

London, Eng., June 27, 1893.

The Westinghouse Electric Company at Pittsburg made an arrangement with the Pennsylvania Railroad Company for a special train to carry those of their employees who wished to visit the Columbian Exposition during the week of the Fourth, the fare for the round trip to be $12. Of this the Westinghouse Company paid $2 on each ticket, making the fare for the employees $10.

ON LIGHT AND OTHER HIGH FREQUENCY PHENOMENA.—VI.

BY NIKOLA TESLA.*

Most of the considerations which apply to the incandescence of a solid, just considered, may likewise be applied to phosphorescence. Indeed, in an exhausted vessel the phosphorescence is, as a rule, primarily excited by the powerful beating of the electrode stream of atoms against the phosphorescent body. Even in many cases, where there is no evidence of such a bombardment, I think that phosphorescence is excited by violent impacts of atoms, which are not necessarily thrown off from the electrode but are acted upon from the same inductively through the medium or through chains of other atoms. That mechanical shocks play an important part in exciting phosphorescence in a bulb may be seen from the following experiment. If a bulb, constructed as that illustrated in Fig. 10, be taken and exhausted with the greatest care so that the discharge cannot pass, the filament *f* acts by electrostatic induction upon the tube *t* and the latter is set in vibration. If the tube *o* be rather wide, about an inch or so, the filament may be so powerfully vibrated that whenever it hits the glass tube it excites phosphorescence. But the phosphorescence ceases when the filament comes to rest. The vibration can be arrested and again started by varying the frequency of the currents. Namely, the filament has its own period of vibration, and if the frequency of the currents is such that there is resonance, it is set easily vibrating, though the potential of the currents be small. I have often observed that the filament in the bulb is destroyed by such mechanical resonance. The filament vibrates as a rule so rapidly that it cannot be seen and the experimenter may at first be mystified. When such an experiment as the one described is carefully performed, the potential of the currents need be extremely small, and for this reason I infer that the phosphorescence is then due to the mechanical shock of the filament against the glass, just as it is produced by striking a loaf of sugar with a knife. The mechanical shock produced by the projected atoms is easily noted when a bulb containing a button is grasped in the hand and the current turned on suddenly. I believe that a bulb could be shattered by observing the conditions of resonance.

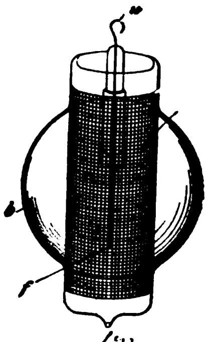

Fig. 31

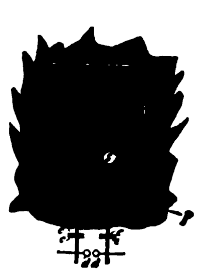

Fig. 32

Showing the Inefficiency of a Metal Screen.

Fig. 32.—Electrostatic Action Between Primary and Secondary, with Extremely High Frequencies.

In the experiment before cited it is, of course, open to say that the glass tube upon coming in contact with the filament retains a charge of a certain sign upon the point of contact. If now the filament again touches the glass at the same point while it is oppositely charged, the charges equalize under evolution of light. But nothing of importance would be gained by such an explanation. It is unquestionable that the initial charges given to the atoms or to the glass play some part in exciting phosphorescence. So, for instance, if a phosphorescent bulb be first excited by a high frequency coil by connecting it to one of the terminals of the latter and the degree of luminosity noted, and then the bulb be highly charged from a Holtz machine by attaching it preferably to the positive terminal of the machine, it is found that when the bulb is again connected to the terminal of the high frequency coil the phosphorescence is far more intense. On another occasion I have considered the possibility of some phosphorescent phenomena in bulbs being produced by the incandescence of an infinitesimal layer on the surface of the phosphorescent body. Certainly the impacts of the atoms are powerful enough to produce intense incandescence by the collisions, since they bring quickly to a high temperature a body of considerable bulk. If any such effect exists, then the best appliance for producing phosphorescence in a bulb, which we know so far, is a disruptive discharge coil giving an enormous potential with but few fundamental discharges, say 25-30 per second, just enough to produce a continuous impression upon the eye. It is a fact that such a coil excites phosphorescence under most any condition and at all degrees of exhaustion, and I have observed effects which appear to be due to phosphorescence even at ordinary pressures of the atmosphere, when the potentials are extremely high. But if phosphorescent light is produced by the equalization of charges of electrified atoms (whatever this may mean ultimately), then the higher the frequency of the impulses or alternate electrifications, the more economical will be the light production. It is a long known and noteworthy fact that all the phosphorescent bodies are poor conductors of electricity and heat, and that all bodies cease to emit phosphorescent light when they are brought to a certain temperature. Conductors, on the contrary, do not possess this quality. There are but few exceptions to the rule. Carbon is one of them. Becquerel noted that carbon phosphoresces at a certain elevated temperature preceding the dark red. This phenomena may be easily observed in bulbs provided with a rather large carbon electrode (say a sphere of six millimetres diameter). If the current is turned on after a few seconds, a snow white film covers the electrode just before it gets dark red. Similar effects are noted with other conducting bodies, but many scientific men will probably not attribute them to true phosphorescence. Whether true incandescence has anything to do with phosphorescence excited by atomic impact or mechanical shocks still remains to be decided, but it is a fact that all conditions which tend to localize and increase the heating effect at the point of impact are almost invariably the most favorable for the production of phosphorescence. So, if the electrode be very small, which is equivalent to saying in general that the electric density is great, if the potential be high, and if the gas be highly rarefied, all of which things imply high speed of the projected atoms, or matter, and consequently violent impacts—the phosphorescence is very intense. If a bulb provided with a large and small electrode be attached to the terminal of an induction coil, the small electrode excites phosphorescence while the large one may not do so, because of the smaller electric density and hence smaller speed of the atoms. A bulb provided with a large electrode may be grasped with the hand while the electrode is connected to the terminal of the coil and it may not phosphoresce; but if instead of grasping the bulb with the hand the same be touched with a pointed wire the phosphorescence at once spreads through the bulb because of the great density at the point of contact. With low frequencies it seems that gases of great atomic weight excite more intense phosphorescence than those of smaller weight, as for instance, hydrogen. With high frequencies the observations are not sufficiently reliable to draw a conclusion. Oxygen, as is well known, produces exceptionally strong effects, which may be in part due to chemical action. A bulb with hydrogen residue seems to be most easily excited. Electrodes which are most easily deteriorated produce more intense phosphorescence in bulbs, but the condition is not permanent because of the impairing of the vacuum and the deposition of the electrode matter upon the phosphorescent surfaces. Some liquids, as oils for instance, produce magnificent effects of phosphorescence (or fluorescence ?), but they last only a few seconds. So if a bulb have a trace of oil on the walls and the current is turned on, the phosphorescence only persists for a few moments until the oil is carried away. Of all bodies so far tried, sulphide of zinc seems to be the most susceptible to phosphorescence. Some samples obtained through the kindness of Prof. Henry, in Paris, were employed in many of these bulbs. One of the defects of this sulphide is that it loses its quality of emitting light when brought to a temperature which is by no means high. It can therefore be used only for feeble intensities. An observation which might deserve notice is that when violently bombarded from an aluminum electrode it assumes a black color, but singularly enough, it returns to the original condition when it cools down.

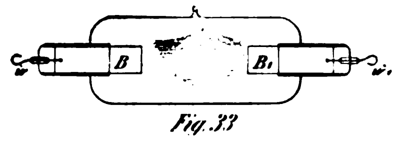

Fig. 33

Carbon Deposit in Tube in a Magnetic Field.

The most important fact arrived at in pursuing investigations in this direction is that in all cases it is necessary in order to excite phosphorescence with a minimum amount of energy to observe certain conditions. Namely, there is always, no matter what the frequency of the currents, degree of exhaustion and character of the bodies in the bulb, a certain potential (assuming the bulb excited from one terminal) or potential difference (assuming the bulb to be excited with both terminals) which produces the most economical result. If the potential be increased, considerable energy may be wasted without producing any more light, and if it be diminished, then again the light production is not as economical. The exact condition under which the best result is obtained seems to depend on many things of a different nature, and it is to be yet investigated by other experimenters, but it will certainly have to be observed when such phosphorescent bulbs are operated, if the best results are to be attained.

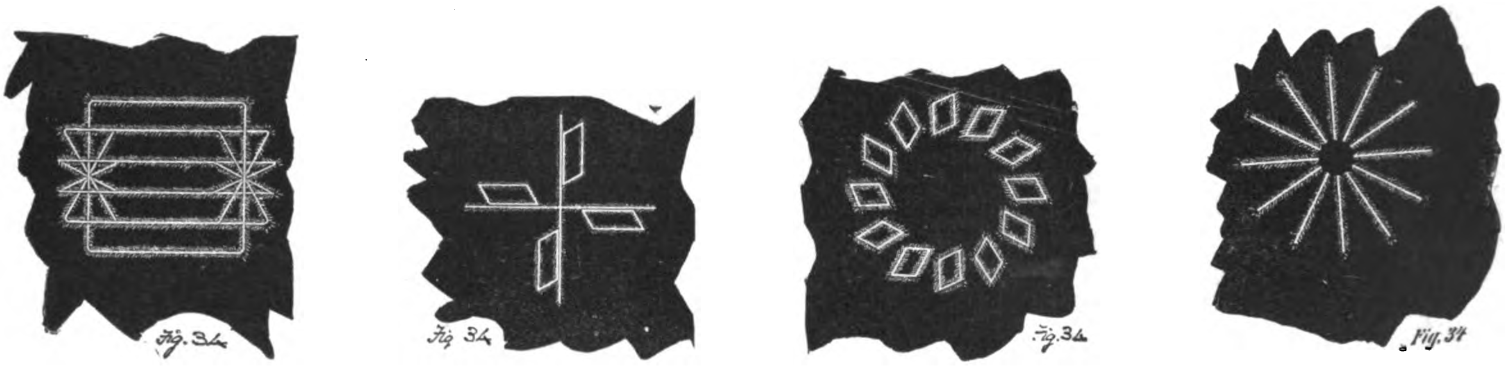
Coming now to the most interesting of these phenomena, the incandescence or phosphorescence of gases, at low pressures or at the ordinary pressure of the atmosphere, we must seek the explanation of these phenomena in the same primary causes, that is, in shocks or impacts of the atoms. Just as molecules or atoms beating upon a solid body excite phosphorescence in the same or render it incandescent, so when colliding among themselves they produce similar phenomena. But this is a very insufficient explanation and concerns only the crude mechanism. Light is produced by vibration which goes on at a rate almost inconceivable. If we compute, from the energy contained in the form of known radiations in a definite space the force which is necessary to set up such rapid vibrations, we find that though the density of the ether be incomparably smaller than that of any body we know, even hydrogen, the force is sometimes surpassing comprehension. What is this force, which in mechanical measure may amount to thousands of tons per square inch ? It is electrostatic force in the light of modern views. It is impossible to conceive how a body of measurable dimensions could be charged to so high a potential that the force would be sufficient to produce these vibrations. Long before any such charge could be imparted to the body it would be shattered into atoms. The sun emits light and heat, and so does an ordinary flame or incandescent filament, but in neither of these can the force be accounted for if it be assumed that it is associated with the body as a whole. Only in one way may we account for it, namely, by identifying it with the atom. An atom is so small that if it be charged by coming in contact with an electrified body and the charge be assumed to follow the same law as in the case of bodies of measurable dimensions, it must retain a quantity of electricity which is fully capable of accounting for these forces and tremendous rates of vibration. But the atom behaves singularly in this respect, it always takes the same "charge."

It is very likely that resonant vibration plays a most important part in all manifestations of energy in nature. Throughout space all matter is vibrating, and all rates of vibration are represented, from the lowest musical note to the highest pitch of the chemical rays, hence an atom, or complex of atoms, no matter what its period, must find a vibration with which it is in resonance. When we consider the enormous rapidity of the light vibrations, we realize the impossibility of producing such vibrations directly with any apparatus of measurable dimensions, and we are driven to the only possible means of attaining the object of setting up waves of light by electrical means and economically, that is, to affect the molecules or atoms of a gas, to cause them to collide and vibrate. We then must ask ourselves—How can free molecules or atoms be affected ?

It is a fact that they can be affected by electrostatic force, as is apparent in many of these experiments. By varying the electrostatic force we can agitate the atoms and cause them to collide under evolution of heat and light. It is not demonstrated beyond doubt that we can affect them otherwise. If a luminous discharge is produced in a closed exhausted tube, do the atoms arrange themselves in obedience to any other but electrostatic force acting in straight lines from atom to atom ? Only recently I investigated the mutual action between two circuits with extreme rates of vibration. When a battery of a few jars (*c c c c*, Fig. 32) is discharged through a primary P of low resistance (the connections being as illustrated in Figs. 19*a*, 19*b* and 19*c*), and the frequency of vibration be many millions, there are great differences of potential between points on the primary not more than a few inches apart. These differences may be 10,000 volts per inch, if not more, taking the maximum value of the E. M. F. The secondary *s* is therefore acted upon by electrostatic induction, which is in such extreme cases of much greater importance than the electro-dynamic. To such sudden impulses the primary as well as the secondary are poor conductors, and therefore great differences of potential may be produced by electrostatic induction between adjacent points on the secondary. Then sparks may jump between the wires, and streamers become visible in the dark if the light of the discharge through the spark gap *d d* be carefully excluded. If now we substitute a closed vacuum tube for the metallic secondary *s*, the differences of potential produced in the tube by electrostatic induction from the primary are fully sufficient to excite portions of it; but as the points of certain differences of potential on the primary are not fixed, but are generally constantly changing in position, a luminous band is produced in the tube, apparently not touching the glass, as it should, if the points of maximum and minimum differences of potential were fixed on the primary. I do not exclude the possibility of such a tube being excited only by electro-dynamic induction, for very able physicists hold this view; but in my opinion there is as yet no positive proof given that atoms of a gas in a closed tube may arrange themselves in chains under the action of an electromotive impulse produced by electro-dynamic induction in the tube. I have been unable so far to produce striæ in a tube, however long and at whatever degree of exhaustion, that is, striæ at right angles to the supposed direction of the discharge or the axis of the tube, but I have distinctly observed in a large bulb, in which a wide luminous band was produced by passing a discharge of a battery through a wire surrounding the bulb, a circle of feeble luminosity between two luminous bands, one of which was more intense than the other. Furthermore, with my present experience I do not think that such a gas discharge in a closed tube can vibrate, that is, vibrate as a whole. I am convinced that no discharge through a gas can vibrate. The atoms of a gas behave very curiously in respect to sudden electric impulses. The gas does not seem to possess any appreciable inertia to such impulses, for it is a fact that the higher the frequency of the impulses with the greater freedom does the discharge pass through the gas. If the gas possesses no inertia then it cannot vibrate, for some inertia is necessary for the free vibration. I conclude from this that if a lightning discharge occurs between two clouds there can be no oscillation, such as would be expected considering the capacity of the clouds. But if the lightning discharge strikes the earth, there is always vibration—in the earth, but not in the cloud. In a gas discharge each atom vibrates at its own rate, but there is no vibration of the conducting gaseous mass as a whole. This is an important consideration in the great problem of producing light economically, for it teaches us that to reach this result we must use impulses of very high frequency and necessarily also of high potential. It is a fact that oxygen produces a more intense light in a tube. Is it because oxygen atoms possess some inertia and the vibration does not die out instantly? But then nitrogen should be as good and chlorine and vapors of many other bodies much better than oxygen, unless the magnetic properties of the latter enter prominently into play. Or, is the process in the tube of an electrolytic nature? Many observations certainly speak for it, the most important being that matter is always carried away from the electrodes, and the vacuum in a bulb cannot be permanently maintained. If such process takes place in reality, then again must we take refuge in high frequencies, for with such electrolytic action should be reduced to a minimum, if not rendered entirely impossible. It is an undeniable fact that with very high frequencies, provided the impulses be of a harmonic nature, like those obtained from an alternator, there is less deterioration and the vacua are more permanent. With disruptive discharge coils there are sudden rises of potential and the vacua are more quickly impaired, for the electrodes are deteriorated in a very short time. It was observed in some large tubes, which were provided with heavy carbon blocks B B_1 connected to platinum wires w w_1 (as illustrated in Fig. 33), and which were employed in experiments with the disruptive discharge instead of the ordinary air gap, that the carbon particles under the action of the powerful magnetic field in which the tube was placed, were deposited in regular fine lines in the middle of the tube as illustrated. These lines were attributed to the deflection or distortion of the discharge by the magnetic field, but why the deposit occurred principally where the field was most intense did not appear quite clear. A fact of interest, likewise noted, was that the presence of a strong magnetic field increases the deterioration of the electrodes, probably by reason of the rapid interruptions it produces, whereby there is actually a higher E. M. F. maintained between the electrodes.

---

* A lecture delivered before the Franklin Institute at Philadelphia, Feb. 24, 1893, and before the National Electric Light Association at St. Louis, Mo., March 1, 1893.



Some of the Designs Produced by Intermittent Discharges · [1] Drum Winding, [2] Alternate Motor Winding, [3] Ring Winding, [4] Spoke Wheel.

Much would remain to be said about the luminous effects produced in gases at low or ordinary pressures. With the present experiences before us we cannot say that the essential nature of these charming phenomena is sufficiently known. But investigations in this direction are being pushed with exceptional ardor. Every line of scientific pursuit has its fascinations, but electrical investigation appears to possess a peculiar attraction, for there is no experience or observation of any kind in the domain of this wonderful science which would not forcibly appeal to us. Yet to me it seems that of all the many marvelous things we observe, a vacuum tube, excited by an electric impulse from a distant source, bursting forth out of the darkness and illuminating the room with its beautiful light, is as lovely a phenomenon as can greet our eyes. More interesting still it appears when, reducing the fundamental discharges across the gap to a very small number and waving the tube about we produce all kinds of designs in luminous lines. So, by way of amusement, I take a straight long tube, or a square one, or a square attached to a straight tube, and by whirling them about in the hand I imitate the spokes of a wheel, a Gramme winding, a drum winding, an alternate current motor winding, etc. (Fig. 34). Viewed from a distance the effect is weak and much of its beauty is lost, but being near or holding the tube in the hand one cannot resist its charm.

In presenting these insignificant results I have not attempted to arrange and co-ordinate them as would be proper in a strictly scientific investigation in which every succeeding result should be a logical sequence of the preceding, so that it might be guessed in advance by the careful reader or attentive listener. I have preferred to concentrate my energies chiefly upon advancing novel facts or ideas which might serve as suggestions to others, and this may serve as an excuse for the lack of harmony. The explanations of the phenomena have been given in good faith and in the spirit of a student prepared to find that they admit of a better interpretation. There can be no great harm in a student taking an erroneous view, but when great minds err the world must dearly pay for their mistakes.

(*Concluded.*)

An Electric Conduit System.

The Hieatzman electric conduit system, a Baltimore invention, has recently been introduced by Hieatzman Bros. of that city, who are the inventors of the system.

The arrangement adopted is to place two conductors of the same polarity in a single conduit which is situated between the inner rails of a double track and contains two parallel slots, one of which is used by the car on the adjacent track. The object of this arrangement is to reduce the cost of construction by utilizing a single conduit for both tracks, and as the space occupied is the highest point of the road the conduit is less susceptible to the street drainage than when placed between the rails of a single track. In equipping existing roads the conduit is independent of the tracks and may thus be constructed without disturbing or relaying the tracks.

Instead of a copper conductor, as usually employed for the trolley wire, heavy steel rails are used, and the conduits are designed to be about three feet deep, so as to accommodate any extra circuits desired. The return current for the railway is carried by the track as in the overhead trolley system.

Boston Notes.

Notwithstanding the stringency in the money market, the work on electric street railways goes along developing and expanding throughout New England; and the American Railroad Improvement Company of this city, Mr. George A. Beatey, treasurer and general manager, is securing quite a large share of the contracts. A large staff of men employed by this company has started on the construction of a new road that is to connect Braintree with Rudolph, Holbrook, Weymouth, Hingham and Nantasket Beach.

During the past two weeks the two formidable Russian warships, the Dimitre Donskoi and Rynda, which took part in the Columbian pageant, have been at anchor in Boston harbor, the reason of their coming being to have a part in the inauguration of the monument erected to the memory of Admiral Farragut in Marine Park, South Boston. On the evening of July 4th these two ships, together with the U. S. warship San Francisco and torpedo boat Vesuvius, were brilliantly illuminated by variegated colored electric lamps from stem to stern and right to the mastheads. During the evening the thousands of lights were shut off, and the powerful searchlights were brought into play, producing some weird effects among the shipping in the harbor. For hours thousands of spectators thronged the water front, such a brilliant display of electric lights and fireworks never having been before witnessed in Boston harbor.

There was quite a blaze on Wednesday in the building formerly occupied as New England headquarters of the Edison General Electric Company before the consolidation on Otis street, Boston. In the extensive salesroom and the superbly fitted blue and white showrooms were many handsome electric and combination fittings which were considerably damaged by fire, smoke and water. The fire is thought to have been caused by an electric wire.

The electrical supply houses of Boston are naturally feeling the effects of the present uncertainty in trade, and so are not rushing shipments at the same rate they were ten days or a fortnight ago. Nevertheless they are all getting their stocks in order, for they all have the assurance that as soon as the present tightness relaxes, as it must shortly do, their customers' stocks will have become so depleted that a big boom in orders will be experienced and they desire to be ready for the rush.

A new piece of apparatus has been patented recently by a Boston inventor, having for its purpose the operating of the switches on street railways by means of electricity, the apparatus being set in motion by the driver or motorman of each car as he approaches the switch. The device has been examined and tested by engineers, electricians and railroad men and they report very favorably upon it.

The unique and efficient electric burglar alarm system in use at the Security Safe Deposit vaults in this city, a fully illustrated description of which we published in our columns last December, has proved so great a success that the company using it now finds itself enjoying the largest number of clients and with more valuable property entrusted to its care than any similar company in Boston. A new and artistic circular, calling attention to this apparatus as securing the most absolute safety, has just been issued, and is still further increasing the business done by the Security Safe Deposit Company.

The North Shore Traction Company, which at present is operating more miles of railway track than any other company in New England, it being composed of Philadelphia, New York, Boston and Lynn capitalists, is reported as having in contemplation the purchase of the Essex, Beverly and Gloucester street railway, which would give it a continuous line from Boston to Gloucester, a distance of over forty miles. The company may also engage in freight as well as passenger traffic in time.

General News.

What is Going on in the Electrical World.

Hillsdale, Mich.—The council has decided to get a Westinghouse electric lighting plant to cost $14,000.

Calais, Me.—An electric road is to be built here, extending to St. Stephen, as soon as council decides upon a route.

Sing Sing, N. Y.—The Sing Sing Electric Railway Company intends to extend its line to Pleasantville on the Harlem Road.

Weston, W. Va.—The electric light plant here was totally destroyed by fire on the morning of the 3d inst.; loss $10,000, insured for $1,500.

Flushing, L. I.—The board of trustees will consider the question of awarding the contract for an electric fire alarm system on July 18.

Norfolk, Va.—Preparations for the change from the present horse cars to the electrical system are being made by the street car company.

Batavia, N. Y.—The council has authorized its light and lamp committee to advertise for bids for a complete electric lighting plant for the city.

Florence, S. C.—The business men of this city and of Darlington are being canvassed with success in regard to establishing telephone exchanges in the two places.

Cleveland, Ohio.—Fifteen thousand street car tickets were stolen from the Cleveland Electric Railway Company's office last week. They represent a value of about $700.

Milwaukee, Wis.—The Milwaukee Electric Railroad, known also as the Hinsey line, is now the property of Charles F. Pfister, who bought it at receiver's sale for $200,000.

Whitesboro, N. Y.—The Utica Electric Light Company has been awarded the contract for lighting this village, and will do it directly from the Utica plant by special wires.

San Jose, Cal.—An extension of time has been asked for the completion of the electric railway between San Jose and Los Gatos, a franchise for which was granted some time ago.

Middletown, N. Y.—The Middletown and Goshen Traction Company have been granted a franchise for the electric road they propose building between this city and Goshen.

Jefferson, Iowa.—At a special election held here on granting a twenty year franchise for electric lighting, the local electric light company carried the day by a large majority.

Indianapolis, Ind.—Judge Brown has rendered a decision transferring the cause of the City Railway Company against the Citizens' Street Railroad Company to the Federal Court.

Marion, Ind.—An electric railway between Marion and Pennville, to run by way of Montpelier, is being talked of here, and several local capitalists have expressed a willingness to aid the project.

Niagara Falls, N. Y.—The contract for street lighting awarded to the Buffalo and Niagara Falls Electric Light and Power Company has been duly executed and the construction of the power house is begun.

Buffalo, N. Y.—Surveys have been completed for an electric road to be known as the Buffalo, South Shore and Hamburg Electric Railway, and running to points on the lake shore between Buffalo and Hamburg.

Brooklyn, N. Y.—All of the horse cars on Fulton street east of the City Hall have been superceded by the trolley and only three horse lines run to Fulton Ferry where a short time ago there were a score of them.

St. Louis, Mo.—St. Louis will within a few weeks have the most complete electric car system in the world. Only two of the old horse lines remain to be converted into electric systems, and they will make the change in a short time.

Montgomery, Ala.—The Cloverdale Electric Street Railway was sold on the 3d inst., under a decree of the City Court, and was bid in for Townsend & Brown, the contractors who built the road, at $3,000. The road has six miles of track.

Denver, Col.—The Western Union has reduced its rates here from 40 cents for ten words to 25 cents. Among the places to be benefited by the reduction besides Denver are Colorado Springs, Pueblo, Canon City, Leadville, Aspen, La Junta and all intermediate towns.

Salt Lake, Utah.—Robert M. Jones has been granted a franchise for electric lighting and transmission of electrical currents for all purposes in this city for a period of twenty-five years. Mr. Jones will transmit current from his Big Cottonwood Cañon power plant.

Fair Haven, Conn.—The Hon. James R. Langdon, of Montpelier, Vt., has purchased the land on which Carver's Falls are situated, about three miles from this city, and will use the water power at that place in generating electricity. About 2,000 horse power will be developed.

San Francisco.—The palatial mansion which Ralph Brisbane Nonesuch, the South African diamond millionaire, is building in the Temescal district, near this city, is to be electrically equipped so as to have all the heating, lighting, cooking and ventilation done by electricity.

Madison, Wis.—The street lighting committee of the city council has advertised for bids for doing the city lighting for a period of years by private corporation, and also for putting in an electric lighting plant for the city complete except grounds and building, which the city now has.

Missoula, Mont.—The purpose of the Missoula Electric Light Company to erect a dam and power house on the Missoula River at a point about a mile up from this town has been checked by a suit brought by J. D. Morgan contesting the validity of the transfer of the site on which the dam was to be built.

Mt. Sterling, Ky.—The Mt. Sterling Gas Company and the Citizens' Electric Light Company (Thomson-Houston) will consolidate July 15. The Electric Light Company will increase their facilities with the object of furnishing power for an electric car line to Sharpsburg now under contemplation.

San Antonio, Tex.—There are two companies—the San Antonio and the Citizens' Electric Street Railway—constructing almost parallel lines to Dignowity Hill, an attractive suburb, and several hundred men are making the dirt fly on both lines in a race for the coveted advantage of "getting there" first. Gangs are working night and day.

Portsmouth, Ohio.—An electric street railway line here is now an assured fact. The contract for building the road, power house, etc., has been awarded, and work is begun. The officers of the company are: President, George Davis; vice-president, Floyd L. Smith; secretary and treasurer, Sam. B. Timmonds.

Lockport, N. Y—A company is to be formed here to build and operate an electric road to Williamsville. The road will be about 13 miles long and will cost $100,000. After it is completed the electric line from Buffalo to Lockport, by way of Williamsville, will, it is said, be nine miles shorter than any steam road connecting the two places.

Elizabeth, N. J.—The board of aldermen, being of the penny-wise and pound-foolish order, are in favor of lightening the burden of taxation by excessive demands on persons or corporations desiring franchises. The mayor of the city, on the contrary, says that Elizabeth should offer more encouragement to enterprises that would help to build it up and especially electric street railways.

Bangor, Me.—The Hampden and Winterport Electric Railroad and Light Company have elected the following directors: J. Manchester Haynes, Geo. E. Macomber, of Augusta; H. L. Shepherd, of Rockport; Edward W. Mayo, of Hampden; Henry A. Mitchell, Eugene C. Nichols, of Bangor, and Fred Atwood, of Winterport.

Gloversville, N. Y.—The opening of the electric line between Gloversville and Fonda the other day was celebrated with great eclat. All along the line in Gloversville, Johnstown and Fonda the houses and the places of business were gayly decorated and everybody evinced an enthusiasm which showed that the new road was a welcome enterprise to the people.

Washington, D. C.—The Washington and Arlington Electric Railway has passed under the control of a Philadelphia syndicate, two-thirds of the former stockholders having accepted 50 cents on the dollar for their shares. A transfer of the property to the new owners will be made as soon as possible, when steps will be taken to complete the road into Washington, which will necessitate the building of a bridge across the Potomac.

Shreveport, La.—Through Percy Thompson & Company, investment bankers, New York, the Belt Line Electric Road and the Short Electric Road of this city have been consolidated and placed under one management. The company is now operating fifteen miles of road and proposes to extend the line five miles further. The consolidated securities of the company were sold by Percy Thompson & Company.

Worcester, Mass.—The franchise granted about a year ago to the Quinsigamond Electric Light and Power Company to supply electric lights in this city has been revoked by the State Gas and Electric Light Commission on the ground "that a competing company is not desirable, because it would needlessly encumber the streets with wires, it would not furnish light or power more cheaply than the present company, and there would be danger of consolidation or absorption with consequent 'stock development' and an increased tax on consumers."

Nashville, Tenn.—The new cars of the Overland electric line in this city are peculiar in construction, and were designed by the president of the road. They are open at each end, with seats for eight persons on each platform, and have a closed section in the centre with twenty seats. The entire car can be thrown open when needed and all the seats face in the direction the car is going, with an aisle in the centre. The cars are twenty-seven feet long.

Providence, R. I.—The Pawtuxet Valley Electric Street Railway Company, incorporated nearly two years ago to build and operate an electric street railway in the Pawtuxet Valley, has completed its organization by electing new officers, as follows: Nelson W. Aldrich, president; Henry L. Greene of River Point, vice-president; H. V. A. Joslin, secretary; Cyril A. Babcock, treasurer; directors, Nelson W. Aldrich, Henry L. Greene, Enos Lapham, Charles H. Perkins, Marsden J. Perry, Gorham P. Pomroy, William G Roelker, Arthur H. Watson, Webster Knight, Henry V. A. Joslin, Cyril A. Babcock.

Chloride of Silver vs. Aluminum-Iodine Cells.

To the Editor of ELECTRICITY:

DEAR SIR: We notice in your issue of June 28th an article entitled "The Aluminum-Iodine Portable Testing Set, manufactured by Queen & Company, of Philadelphia, or more properly speaking, a comparison of E. M. F. between the aluminum-iodine and the chloride of silver cell. In reply to this article we desire to say that there are several points which need correction, and which the author no doubt failed to recognize in his composition.

In the first place, our present form of chloride of silver dry cell has an E. M. F. of about one volt.

Secondly, there is absolutely no local action, so that there is, not only practically but positively, no waste of the elements while not in use.

Thirdly, a chloride of silver cell can be made with an E. M.

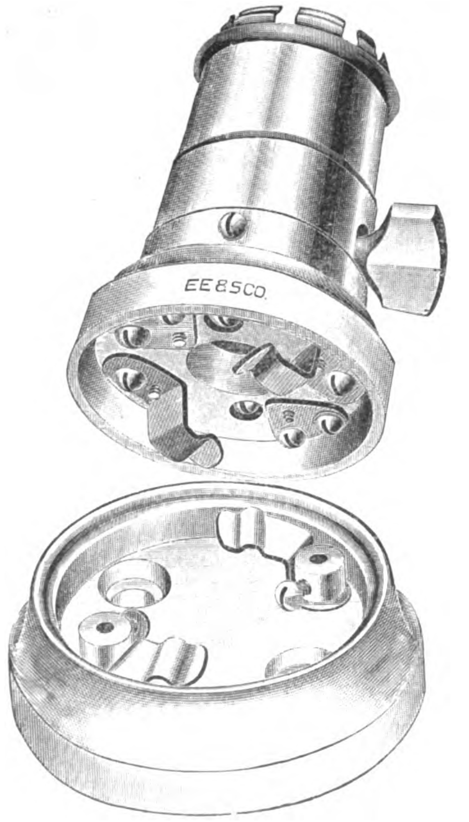
F. of not only 1.4 volts, but with from 1.5 to 1.6 volts. But why did we not bring such cells prominently before the electrician? Simply from the fact that they were too closely related to the aluminum-iodine cell, in which the local action, which you state is practically eliminated, was nevertheless still going on, and however slight, resulted in inevitable ruin to the elements. For this reason we preferred our one volt cell, which is devoid not only of any injurious waste but of any waste whatever, to a cell of 1.5 volts in which a local action of the slightest nature would invariably mean destruction.

We regret exceedingly that we are not now in a position to go into such details as we would desire, for the manufacturers of the aluminum-iodine cell have placed before us a barrier which we cannot at present overcome, by refusing to place in our hands a cell of their production. . . . Respectfully,

THE CHLORIDE OF SILVER DRY CELL BATTERY COMPANY.
Baltimore, July 5.

The E. E. and S. Fusible Wall Socket.

The combination represented in the illustrations accompanying this notice is said to give universal satisfaction. It is the well-known E. E. & S. socket with fused



THE E. E. AND S. FUSIBLE WALL SOCKET.

detachable base and wall standard, manufactured by the Electric Engineering and Supply Company of Syracuse. The contrivance has a number of good points. The porcelain is tough and strong, the parts are well made and carefully finished, and it is neat and attractive in appearance.

As the two parts of the base are not fastened by screws, no tools are needed to separate them, a simple quarter turn being sufficient, and the contact is always sure. A special feature is the fact that the fuse is carried on the removable part. When necessary to replace the former the socket is removed and the work done without danger of accident or short circuit.

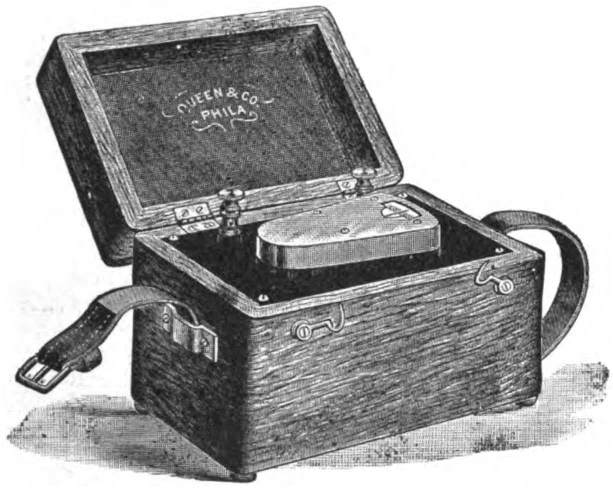
This combination can be used in many cases instead of more expensive fittings, for side brackets, temporary and advertising work, where rosettes and cut-outs would otherwise be necessary. The company makes them with either Edison, Thomson-Houston or Sawyer-Man key or keyless sockets.

Queen Portable D'Arsonval Galvanometer.

In completing a line of portable testing instruments Queen & Company, Philadelphia, have placed on the market a D'Arsonval Galvanometer, as illustrated, which deserves more than passing notice. It is of the type used heretofore in their testing sets, and is admirably adapted to laboratory or station measurements and for use as a detector of faults in line wire. The Index is quite dead beat, so that rapid readings are possible, and because of the principle of construction employed, magnetic fields and mechanical vibrations produce practically no effect.

As the Galvanometer is a "zero" instrument, readings cannot be made by direct deflection, but to determine resistance a rheostat and bridge are necessary exactly as in regular testing sets.

For manufacturing companies, especially where quick work is an item, the above will prove of much value. It is well suited for ascertaining the resistance of carbon filaments for incandescent lamps, and has been used for this purpose by some of the large lamp makers. As a simple ground detector the Galvanometer is quite complete in itself, being conveniently mounted in a handsome mahogany case with leather strap.



QUEEN PORTABLE D'ARSONVAL GALVANOMETER.

COMMERCIAL PARAGRAPHS.

In ordering a fresh supply of brushes for the motors made by the Boston Motor Company and in use at the Lawrence Scientific School, Harvard University, one of the professors says that the motors work splendidly. Another correspondent in forwarding a repeat order for a fan equipment, says that though these motors are like small toys they are as scientifically and well made as any large sized motors now on the market. These and many similar endorsements prove the popularity of the Boston Motor, which now sells like hot cakes.

The "Novak" lamp is making a great record for itself wherever used, and nowhere more satisfactorily than at the World's Fair. In the Libbey Glass Company's Factory, which is one of the chief attractions at the Exposition, 1,200 "Novak" lamps were installed and went into service May 1st, since which date they have been in regular use. With the exception of 35 lamps, the bulbs or filaments of which have been broken by accident, the whole 1,200 are burning with as great brilliancy as when first installed. This must be very gratifying to all interested in the Waring Electric Company, which manufactures this first-class lamp.

INCORPORATIONS.

The McCay-Howard Engineering Company, Baltimore, Md.—to deal in electric light plants and power plants and other business in which electricity through wire is applied. Capital stock, $5,000. Promoters: H. K. McCay, B. Howard, A. H. McCay, A. Hamilton, S. Post, L. E. Wolfe.

The Pittsburg, Crafton and Mansfield Street Railway Company Pittsburg, Pa.—to construct and operate an electric railway in Allegheny County, Pa. Capital stock, $500,000. Promoters: Thos. S. Bigelow, Wm. J. Burns, John E. Reilly, Pittsburg.

The Pentz Reckenzann Electric Company, Philadelphia, Pa.—to manufacture electric meters and other electrical apparatus and appliances. Capital stock, $30,000. Promoters: A. J. DeCamp, Chas. D. Horton, L. Webster Fox, Chas. Schaffer, Philadelphia; Lincoln Godfrey, Merion, Pa.

The College and Grandview Electric Street [illegible] Company, Beaver Falls, Pa.—to construct and [illegible] electric railway in College Hill Borough, Beaver [illegible] Pa. Capital stock, $15,000. Promoters: Chas. P. [illegible] John P. Sherwood, A. R. Loyds, Beaver Falls.

The American Burglar Alarm and District Telegraph Company, at Oakland, Cal. Capital stock, $50,000. Directors: A. H. Hogg, D. S. Henderson, A. G. Gunnett, [illegible] Graham and Cary Howard. The objects of the corporation are to operate and maintain a district burglar alarm and telegraph systems, also to operate electric light and power machinery and appliances for the distribution of electricity for purposes of lighting, power, or any other purpose for which electricity may be used.

The New Hampton Electric Light and Power Company, New Hampton, Iowa.—to deal in electric light and power. Promoters: T. C. Clary, L. L. Briggs, J. F. Babcock, E. G. Porter, D. K. Gardner, New Hampton.

The West Side and Gordon Park Street Railroad Company, Cleveland, O.—to construct and operate street railroads by electricity or other motive power. Capital stock, $10,000. Promoters: W. C. Scofield, C. W. Scofield, Geo. F. Scofield, S. H. Short and L. A. Russell.

The Elsinore Electric Power and Water Company, Elsinore, Cal.—to erect and conduct electric light and power plants, etc. Capital stock, $200,000. Promoters: Jas. F. Jones, Elsinore; Ray D. Wellman, Redlands; Cal. Dawson, B. Day, Downey, Cal.

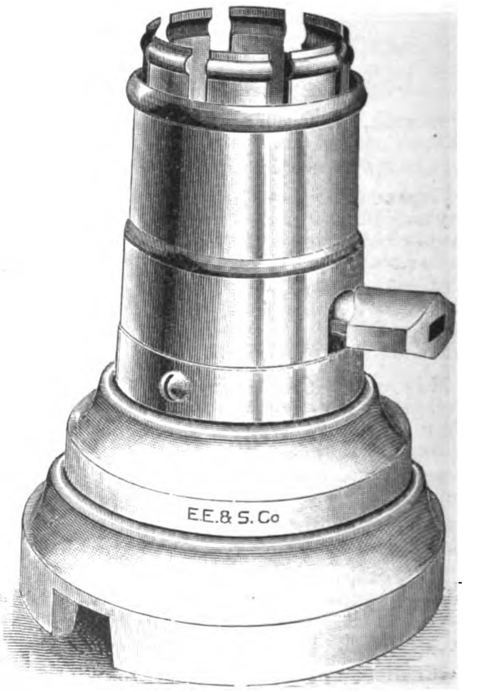
The Louisville and Jeffersonville Terminal Railway Company, Louisville, Ky.—to construct and operate railways by steam, electricity or other motive power. Capital stock, $100,000. Promoters: Dennis Long, Samuel A. Miller, W. L. Lyons, Jos. Huffakes, Jas. W. Baird and Thaddeus W. Spindle.

The Electric Light, Water and Milling Company, Milwaukee, Wis.—to erect and operate water works and electric light plants. Capital stock, $80,000. Promoters: J. Seeveland, J. Davidson and W. Schlosser.

The Adams Electric Manufacturing Company, Chicago, Ill.—to manufacture and deal in all kinds of electrical machinery, appliances and other metallic goods. Capital stock, $500,000. Promoters: Wm. B. Mather, Wm. L. Sutherland, Jas. S. Wheeler, Jr.

The City Illuminating Company, Chicago, Ill.—to furnish light and electricity for houses, streets, etc., distribute electric currents for operation of motors, etc. Capital stock, $6,000. Promoters: M. B. Austin, R. H. Watson and H. W. Ames.

The Chelora Brade Sewage and Electric Light and Power Company, Atlantic City, N. J.—to supply and distribute electricity for electric light, heat and power, etc. Capital stock, $15,000. Promotors: H. Monback, D. S. Dengler, E. Wood, Philadelphia; I. G. Adams, E. Ford, W. Riddle, Atlantic City.



THE E. E. AND S. FUSIBLE WALL SOCKET.

The Cornelius & Rowland Company, Camden, N. J.—to buy, sell and manufacture gas and electrical fixtures, etc. Capital stock, $50,000. Promoters: R. Cornelius, J. Brannen, B. H. Buck, C. Thackera, J. Meadows, Philadelphia; L. Plant, New York City; J. W. Morgan, Camden, N. J.

Articles of incorporation have been filed at Camden, N.J., by the New Jersey Improvement Company, the purposes of the corporation being to equip ready for operation railroads and to construct electric light and power plants, etc. Capital stock, $150,000. Incorporators: Louis C. Maus, Theodore T. Hansen and Benjamin T. Wagner.

MUNICIPAL ELECTRIC LIGHT CO.,
BROOKLYN, N. Y., July 19, 1892.
HENRY A. REED, SEC'Y BISHOP GUTTA-PERCHA CO.

Dear Sir: We can candidly vouch for the superior quality of the Bishop insulation, as it has withstood the weather, falling wires, etc., during our two and a half years' service without accident or trouble of any nature on our aerial lines or in our house wiring. The severe storm of the winter of 1890-'91, which obliged all other plants to "shut down," caused no injury to our alternating circuits. Yours respectfully,

JAMES FERGUSON, *Sup't.*

Electrical Transmission of Intelligence

And Other Advanced Primers of Electricity.

BY PROF. EDWIN J. HOUSTON, A.M.,

Author of

"A Dictionary of Electrical Words, Terms and Phrases," &c., &c., &c.

CLOTH. PRICE, $1.00.

The third and concluding volume of Prof. Houston's Series of Advanced Primers of Electricity is devoted to the telegraph, telephone, and miscellaneous applications of the electric current.

In this volume the difficult subjects of multiple and cable telegraphy and electrolysis, as well as the telephone, storage battery, etc., are treated in a manner that enables the beginner to easily grasp the principles, and yet with no sacrifice in completeness of presentation.

CONTENTS.

I. The Electric Transmission of Intelligence. II. The Electric Telegraph. III. Multiple Telegraphy. IV. Cable Telegraphy. V. Electric Annunciators and Alarms. VI. Time Telegraphy. VII. The Telephone VIII. Electrolysis. IX. Electro-Metallurgy. X. Storage or Secondary Batteries. XI. Electricity in Warfare; Electric Welding. XII. Some Other Applications of Electricity. XIII. Electro-Therapeutics. XIV. Review, Primers of Primers.

PETITION.

To the Honorable ....

Representative in the United States Congress from the ....

District of ....

Your undersigned constituents, being engaged in the manufacture or sale of electrical apparatus, in which business there are large amounts of capital invested in your district, hereby beg to urge upon you to do all in your power to secure Congressional investigation of the plan of organization and methods of doing business of the General Electric Company, whose main offices are at 44 Broad street, New York City, with branch offices in all the large cities and towns of the country.

We urge this action, believing that a thorough and impartial investigation will establish the following :

1. That the said General Electric Company is and has been since its organization conducting its business in direct violation of the laws of the United States.

2. That the said General Electric Company as at present organized and conducted is a formidable barrier in the way of further development in the electrical art, and a standing menace to those concerns of smaller capital engaged in the electrical trade.

3. That the said General Electric Company is and has been making since its organization an entirely unwarranted and illegal use of certain patents granted to it and to its component companies by the United States Patent Office.

4. That it is about to solicit from the honorable body of which you are a member, an extension of United States Patent No. 223,898 (the Edison incandescent lamp patent) which patent expires November 10, 1893.

5. That the best interests of the public demand an open and unrestricted competition in the electrical trade, and a strict enforcement of the law against Trusts.

6. That the General Electric Company is composed of twelve or more sub-companies, which have been absorbed or taken over at various times, and is in its very essence a Trust, conducting its business in defiance of the law.

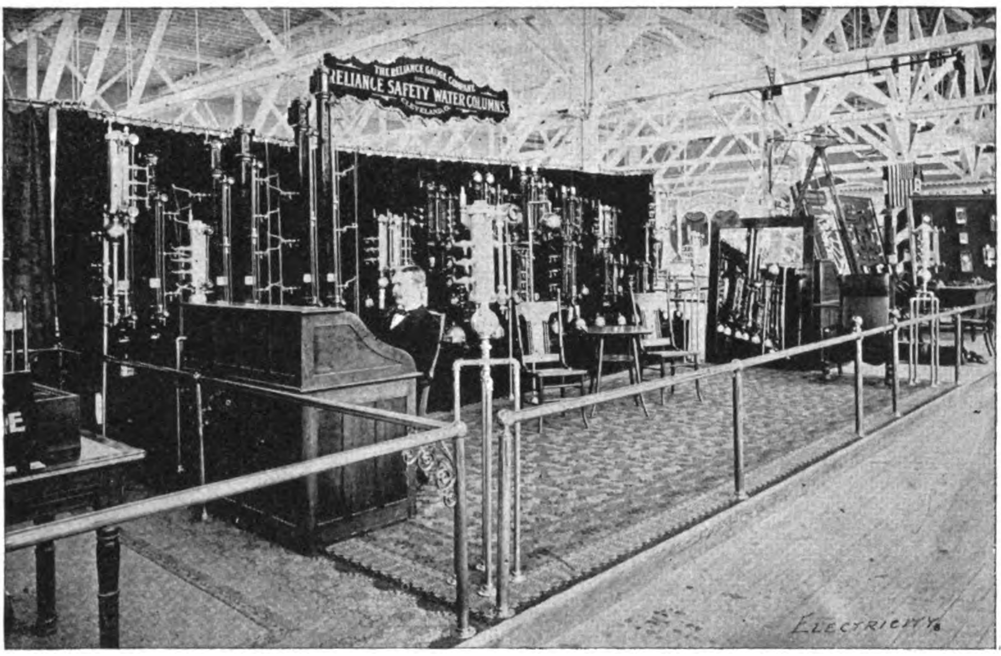
THE NEW ENGLAND BUTT COMPANY'S WORLD'S FAIR EXHIBIT. (SEE PAGE 2.)

World's Fair Notes.

NEW ENGLAND BUTT COMPANY'S EXHIBIT.

Among the interesting exhibits located in the gallery of the Electricity Building is that made by the New England Butt Company. It is especially interesting to that portion of the public that has never before had the opportunity of seeing the insulation put on the wires used for electrical purposes. Seven machines are shown in operation, four of which are double braiders, which show the method of putting on a double coating of insulation. Two others are used as single braiders, and are designed for covering small wire with a single layer for insulation. A six-spindle machine is also shown in operation. This machine is designed for covering the smallest of wires used on magnets. The smallest fraction of insulation can be obtained by a simple adjustment of any one of the six spindles. A heavy braider for making cables is another interesting part of the exhibit. This machine is used in insulating the heavier electric wires, and can be operated so that a compound can be distributed over the surface of the cotton insulation. All of the machines are belted to a line shaft which is in turn belted to an electric motor.



THE RELIANCE GAUGE COMPANY'S WORLD'S FAIR EXHIBIT.

THE RELIANCE GAUGE COMPANY.

The Reliance Gauge Company's exhibit is one of the most attractive exhibits on the second floor of Electricity Building, showing a full line of their celebrated Reliance safety alarm water columns for steam boilers varying in size from 1 to 1,000 horse power. The exhibit is very handsomely and tastefully arranged, the floor being covered with Brussels carpet, the stands with plush, and olive plush draperies for a background. The highly polished aluminum, brass and nickel-plated columns add to the luster, giving to the exhibit a very pretty and attractive effect.

The Reliance safety columns go on the boilers taking the place of the ordinary water columns in every detail, having both the gauge cocks and the water gauges, but on the inside there are two floats and a valve. When the water gets above the third gauge the high water float comes up, raises the valve lever, sounds the alarm for high water at the third gauge, compels the fireman to keep the water down where it should be all the time, also informs his superiors of his carelessness. It is an impossibility for him to get 1-16 of an inch more water in the boiler than he should have at any time without being instantly reported. This insures good dry steam, which to an electrical or power plant is invaluable. When the water falls to the first gauge cock it is as low as it should be allowed to go. When it gets below that point of the gauge cock the float falls by gravity and sounds the alarm for low water at the first gauge cock, calling the attention of the attendant. Another feature of the Reliance column is its trap sediment chamber. With the ordinary water column whenever any mud or foreign matter comes in through the feed pipe it comes up, circulates around through the column, dirties up the water glass, and in fact often stops it up, then falls right back into the feed pipe, only to come back again the next time the gauge cock is tried, but the Reliance column feeds at the side. Every particle of mud which comes in the column is trapped down into the sediment chamber. After once in that, it cannot possibly get back into the column. It holds the mud in the chamber, lets the water free and clear circulate through the column, keeping the glass clean all the time.

The exhibit is in charge of Mr. Geo. B. Clark, who will be pleased to meet his many patrons and friends and all others who are interested. The boilers in Machinery Hall are equipped with these columns, and to see them working practically call in the boiler room, but the aluminum models cut open, showing the working parts, gives one a better idea of their simplicity and value as safeguards.

The following judges were announced last week to pass upon the electrical exhibits in the Electricity Department by the National Commission:

H. S. Carhart, Professor of Physics and Electrical Science, Michigan University, Ann Arbor, Mich.

Michael O'Dea, Professor of Physics, University of Notre Dame, Ind.

Ernest P. Warner, Electrician Western Electric Company, Chicago.

Harris J. Ryan, Professor of Electrical Engineering, Cornell University, New York.

W. M. Stine, Professor of Electrical Engineering, Ohio University, Athens, Ohio.

R. B. Owens, Professor of Electrical Engineering University of Nebraska, Lincoln, Neb.

B. F. Thomas, Professor of Electrical Engineering, Ohio State University, Columbus, Ohio.

T. C. Mendenhall, Washington, D. C.

Samuel Reber, U. S. A.

H. A. Rowland, Baltimore, Md.

Geo. F. Barker, Philadelphia.

The *British* exhibit, which has just been completed, is the most complete in its line shown in the Electricity Building. The display is located in the northwest corner of the building, on the ground floor, and occupies a space of about twenty by forty feet square. The exhibit consists principally of a collection of historical telegraph instruments loaned from Her Majesty's Postmaster's exhibit at South Kensington, and is shown in such a manner that it readily illustrates the advances and the growth and development of the telegraph from the first instrument ever used up to the present. A very interesting part of the exhibit is Delany's telegraph system, which provides for the transmission of six messages simultaneously over the same wire, all in the same direction or divided up in any manner most suitable to the traffic at any moment, thereby enabling the operator to make the maximum use of each circuit. It is interesting to note the great difference between this system and the original fine needle system, which is also exhibited, and which required five wires to transmit one message.

The remainder of the German exhibit is being installed in the middle of the west gallery of the Electricity Building. It will consist of historical apparatus from the Government Museum and from the different German electrical manufacturers. The central portion of the space will be occupied by a bust of Siemens, the sides will be draped with old gold curtains and silk plush portieres.

Among the number killed in the fire which occurred in the cold storage building on the Fair grounds last week was Norman H. Hartman, a wireman in the employ of the Harter Electric Company.

The space formerly assigned to the Spanish Commission for the display of Spanish electrical goods in the Electricity Building has been given to the Newman Clock Company.

The Electric Heat Alarm Company's exhibit, which is in charge of Mr. Ed. Nashold, is credited with having one of the handsomest booths in the building.

Electricity for Marking Meat.

Although electricity has for some time invaded many unexpected places, and is familiar in a number of abattoirs for supplying illumination, a recent suggestion of Mr. Manville, an English electrical engineer, promises to bring butchery still more closely in touch with electricity.

A Parliamentary committee has been appointed in England to make inquiry into the subject of marking meat imported from different countries. Among the witnesses called was Mr. Manville, who proposed an electrical machine, a model of which was presented for the consideration of the committee.

The machine contains a wheel with projections on its circumference consisting of various letters which is supplied with an electric current. When the wheel is rolled along a carcass, the letters are branded on the skin and may be applied very rapidly to any part of the animal. The device is cheaply manufactured, and where electric light is supplied its use would incur only an insignificant expense.

Electrically Welded Steel Barrels.

It is reported that a large industry is being built up at Barrow, Eng., in the production of steel barrels for the conveyance of petroleum. The barrels are made in halves by means of compression in a mold, when hot. Afterward they are welded together by means of electricity. The barrels are intended for use by the large oil carrying companies engaged in the oil trade in the East, where the temperature has a great effect on wood casks, and results in so much leakage.

Practical Aspects of Low Frequency Electrical Resonance.*

BY M. I. PUPIN, PH.D.

A large part of the subject of the following discourse was discussed by me, but in a different way, in three papers. Two of these appeared in the April and May numbers of the *American Journal of Science*. The third will appear in the June number of the same journal. The method which I have adopted in the following discussion seemed preferable to the mathematical method which I followed in those papers. It is probably just as exact, and certainly a much clearer way of viewing the variable flow of electricity, especially those features of it which have a more or less direct practical bearing.

1. ON THE NATURAL PERIOD OF AN ELECTRICAL CIRCUIT.

An electrical circuit possessing self-induction and capacity behaves in a great many respects as a body does in consequence of its inertia and elasticity. The fundamental reason for this analogy is simply this: the electro-magnetic energy of a coil through which a current flows has all the characteristic properties of the kinetic energy of a moving body, whereas the energy of the static charge of a condenser has all the characteristic properties of the potential energy of a strained elastic body. If the neutral state of such an electrical circuit is disturbed, it will return to it again after performing a certain number of oscillations about the position of its neutral state. But a return to the neutral state is impossible until the energy which is spent upon the circuit to disturb its neutral state has left the circuit, or to use a more technical expression, until the energy has been dissipated or given off to some other circuit. The two principal causes which produce dissipation and compel the circuit to return to its neutral state again are frictional resistances and radiation. Just as in the case of vibrating bodies, so also in the case of electrical oscillations, losses due to radiation, especially when no other electrical circuits are near, are exceedingly small when the oscillations are slow. In Herzian oscillations they are quite considerable. In oscillations of the Tesla frequency they are probably not negligible. My remarks refer to electrical oscillations of long period, therefore losses due to frictional resistances are the only losses which I shall consider. Consider now an electrical circuit consisting of a coil *A* and a condenser *B* (Fig. 1) in series with it. It is a circuit with localized self-induction and capacity. I trust that my discussion will lose as little in its generality as it will in its practical bearing if I confine it to such circuits only. Let a sudden electrical impulse disturb the neutral state of the circuit; electrical oscillations will result. These oscillations follow laws practically identical with the laws of the motion of a slowly vibrating body. Their period is constant, as we all know, and it is in general completely determined by *the electro-magnetic moment of inertia* and the *dielectric elasticity* of the circuit—that is, by its coefficient of self-induction and its capacity. When, however, frictional losses due to ohmic resistance, magnetic and dielectric hysteresis are large, then the period of this circuit is no longer defined by the self-induction and capacity alone, but it is also influenced by these frictional losses.

When ohmic resistances and hysteresis losses are small enough, then the natural period of the circuit is given by the well-known formula

$$T = \frac{2\pi}{10^3}\sqrt{L\,C}$$

where T is the natural period of the circuit in seconds, L its coefficient of self-induction in henrys, and C its capacity in microfarads. For instance, a large Bell telephone whose coefficient of self-induction is 0.5 henrys when connected in series to a condenser of 1 microfarad capacity will have a natural period of very nearly $\frac{1}{225}$ seconds, that is to say, an electrical disturbance would set up oscillations in it 225 of which would take place in one second. If a permanent magnet were brought into the vicinity of the telephone coil and then suddenly removed, the telephone would sing a note whose pitch would be a little below the well-known note C. But it would not sing it very long. For since the ohmic resistance is 100 ohms these oscillations would disappear almost entirely after 10 complete oscillations, somewhat in the manner represented in diagram Fig. 2, that is to say, the telephone would sing only during about $\frac{1}{22}$ part of a second. By diminishing the resistance we could prolong its song. But diminish the resistance as much as you please, the pitch of the note of the telephone will remain the same, because, as I said, the natural period of the telephone circuit just described is within wide limits independent of the ohmic resistance.

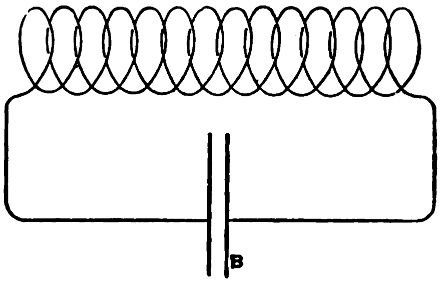


FIG. 1.

2. ON THE TUNING OF AN ELECTRICAL CIRCUIT.

To change the note, say to make it higher, it would be necessary to diminish the capacity of the condenser. When a piano tuner wishes to raise the pitch of a piano string he gives it more tension; so in *tuning an electrical circuit*, in order to change its pitch, it is necessary to change its *electrical elasticity*, that is, its capacity. But there are other ways of tuning an electrical circuit, just as there are different ways of tuning musical instruments. Consider a reed pipe, say a clarionet. The musician places a little bit of wax on the reed. When the instrument is too low in pitch he takes off some of the wax, so as to diminish the moment of inertia of the reed, and when the pitch of the instrument is too high, he sticks on more wax so as to increase the moment of inertia. At any rate this used to be the method of old-fashioned country musicians. And so it is in tuning an electrical circuit. Instead of varying its *electrical elasticity*, that is, its capacity, we can vary its *electro-magnetic moment of inertia*, that is to say, its coefficient of self-induction. To show how this may be done in a telephone circuit just mentioned, insert into this circuit a small coil *a* (Fig. 3) an auxiliary coil, with a removable iron core *c* made up of very fine iron wire. In doing this we do exactly what the country musician does when he puts wax on the reed of his clarionet. If the electrical pitch of the circuit does not suit, say it is too high, then simply put on more electro-magnetic wax, that is to say, insert the iron core and move it back and forth until the correct position is found, which will give the correct electrical moment of inertia, that is to say, the correct coefficient of self-induction. This is, briefly stated, what I mean by the expression *tuning an electrical circuit.* From the simple expression given above for the natural period of an electrical circuit, it is evident that the tuning of an electrical circuit, if not simpler, is certainly quite as simple a process as the tuning of a musical instrument.

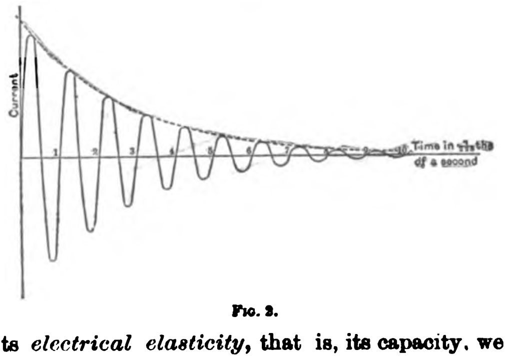

FIG. 2.

3. ON THE DETERMINATION OF THE PITCH OF AN ELECTRICAL CIRCUIT.

If we wish to know the pitch of a musical instrument, say of a tuning fork, to choose a simple illustration, we simply give it an impulse, say a tap with the finger, and then listen to the vibrations, which in general will last for several minutes, and give us sufficient time to make up our minds as to what the vibrations sound like. In examining the pitch of an electrical circuit it is more convenient to adopt a different method. The reason is that as a rule electrical oscillations are, as pointed out in the example above, much more damped, so that the oscillations resulting from a single impulse would not last long enough to give us sufficient time to see what they look like, or to listen and hear what they sound like. The method suggested by the stroke of a violin bow over the string is preferable. The stroke of the bow produces a series of impulses which quickly succeed each other and maintain the string in uniform vibration. It is interesting now to observe that the same thing can be done with an electrical circuit. Consider the circuit A B C, Fig. 4. The condenser B represents the tension on the violin string, coil A represents its inertia. The air gap C stands for the point where the bow by its stroke excites the string. If you now wish a musician who plays with a one-sided stroke, use a high potential direct current generator D, and for an alternating stroke substitute an alternator. The discharges at the air gap C succeeding each other quickly enough, and at proper intervals, will maintain in the circuit A B C practically uniform electrical oscillations. This is one of Tesla's favorite circuits, and I have no doubt but that he will accomplish great things with it yet.* Bring a few turns of wire of a telephone circuit into inductive influence of this circuit, and you will have in the telephone a musical note of exactly the same pitch as the pitch of the electrical oscillations in the circuit A B C. The note is not perfectly pure. It is marred by the noise of the spark discharge of the air gap C Neither is the note of the violin string pure; there is always more or less of the scraping noise of the bow. Just as it is necessary to keep the bow well rosined so as to give a good grip upon the string, so it is necessary to apply a strong current of air or the action of some other of Tesla's devices upon the air gap C, otherwise an arc is formed and the generator D loses its grip upon the circuit A B C.† If we had a number of different coils with condensers like A and B alongside of each other, and arranged in such a way as to be able to place them at will, now the one and now the other, and now again a number of them in multi-

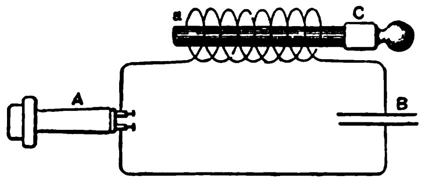

FIG. 3.

---

[*] A lecture delivered at the Tenth General Meeting of the American Institute of Electrical Engineers, Columbia College, New York.

[*] It must be observed, however, that Hertz, in 1887, produced his oscillations by a circuit of this identical form

[†] The importance of blowing out the arc for the production of powerful oscillations seems to have been first organized by H. Classen, *Wiedemann Annal. d. Physik und Chemie*, Band xixxx, p. 647, 1890.

ple under the action of the electrical bow which the generator D keeps moving over the air gap C, and at the same time vary the capacities, we should be able to change the electrical vibrations of our system with that ease, precision and grace which the violin player displays when with the one hand he guides his obedient bow while the busy fingers of the other hand glide over the trembling strings, eliciting from them delightful notes which blend into pleasing harmonies.

So with our system of properly tuned electrical circuits, we could produce harmonies, but they would be harmonies of silence, harmonious oscillations in the ether that affect neither eye, nor ear, nor taste, nor smell. But bring a part of a telephone circuit into inductive action of our harmonic system, and let a skilled experimentalist manipulate a properly constructed keyboard which controls the coils and condensers of the various circuits, and harmonies which before were as silent as the grave will now agitate the responsive diaphragm of the telephone and produce music that could be made to re-echo in every telephone in the United States.

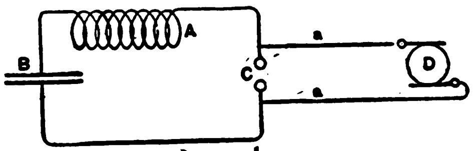

FIG. 4.

But after all, such an arrangement when used for such a purpose would be a mere toy in comparison to the purpose for which our distinguished colleague, Mr. Tesla, employs it. To convert high potential but small current electrical energy into low potential big current energy, or *vice versa*, accompanied by all possible variations in the frequency of oscillation was the purpose for which Mr. Tesla constructed the device. To a physicist who delights, not less than the engineer, in neat, simple devices for the accomplishment of big and brilliant effects this device of Tesla naturally appeals more than all his other ingenious inventions. Many a delightful hour have I spent in watching experiments on a circuit like the one in Fig. 4. The coil A consisted of a short, stout copper wire; the condenser B consisted of a battery of Leyden jars, which my distinguished teacher, Professor Rood, of Columbia College, kindly lent me. The wires *aa* were thin copper wires connecting the air gap C to the poles of an induction coil which is now in the hospital. It is a delightful sight to see the stout wire aglow under the powerful agitation of the rapid oscillations, whereas the thin wires *aa* adjoining them remained perfectly cool. Twist now the thick wire A into a few convolutions, say ten or twelve, and surround them by a few hundred turns of fine wire, and you will have the now well-known oscillatory transformer with which Mr. Tesla and Professor Elihu Thomson produced some brilliant effects, a transformer that will give you any number of volts, especially if—and now I am going to touch a point which forms the central point of my discourse—especially if the thin wire coil contains *capacity in series with it, so that the natural period of this circuit is the same as the period of the thick wire coil, that is, if the two circuits are in resonance.*

4. ON RESONANCE.

Here again I have borrowed a term employed in music. But a few simple considerations will show you that it is very natural that I should, for the phenomena of sound and those of oscillatory flow of electricity are governed by nearly the same laws. Very high frequency electrical oscillations would in all probability be identical with light, as first announced by the immortal Maxwell. It is, therefore, not surprising to find that low frequency electrical oscillations should resemble so much the other group of oscillatory phenomena which next to light pleases our senses best, namely, the phenomena of sound, especially agreeable sound, that is, music.

To gain a clear conception of what is meant by electrical resonance consider the following simple mechanical analogon—I call it the *torsional pendulum.* I used it often with my students in discussing alternating current phenomena and they liked it very much. A heavy bar A (Fig. 5) is suspended on a stiff elastic wire B, which is attached to a plate C whose weight may be neglected. This plate C slides in a groove *aa* which in consequence of friction acts like a brake. Suppose now that the friction between C and *aa* is such that when the angular velocity of C is ω the rate at which heat is generated by the friction between C and *aa* is equal to $\omega^2 R$ where R is independent of the angular velocity. This torsional pendulum resembles then very much an electrical circuit having localized self-induction, capacity and ohmic resistance. The moment of inertia of A, the elasticity of B, and the friction in C act exactly the same as the coefficient of self-induction of the coil, the capacity of the condenser, and the ohmic resistance of the circuit. Let $\frac{1}{B}$ stand for the elastic capacity of the wire, that is, if the wire be twisted through an angle θ, then the moment of the elastic force which opposes this twisting is $\frac{\theta}{B}$. Let I stand for the moment of inertia of the weight A, then as long as the frictional resistance is within certain limits we shall have for the natural period of the pendulum

$$T = 2\pi\sqrt{I \times B}.$$

You see that this expression is exactly the same as the one which expresses the natural period of the circuit in terms of its coefficient of self-induction and capacity.

If this pendulum is set in motion by a single impulse it will oscillate with a constant period. The first elongation will be largest, and the successive elongations will be smaller and smaller, just as represented in Fig. 2, until the pendulum is reduced to rest again. This will happen when the energy of the impulse has been entirely dissipated into heat, which is the work done against frictional resistances in the break at *C*. The smaller this frictional resistance, the longer will the pendulum swing, in consequence of the impulse, before it is reduced to rest. On the other hand we can increase the resistance in *C* to such an extent as to make the swing a-periodic or dead beat, as is for instance the case in the Weston voltmeters and ammeters.

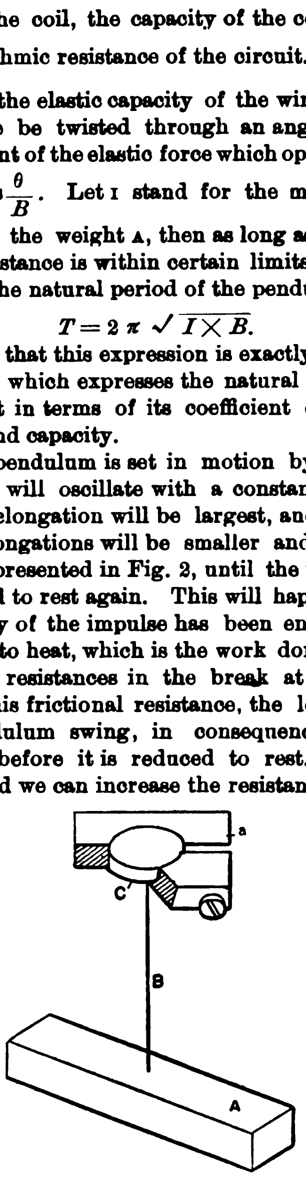

FIG. 5.

Repeat the impulse at regular intervals, alternating them, the pendulum will keep on swinging; but you can easily see that if the intervals of the impulses are measured off in such a way that every time the pendulum passes through its position of equilibrium the impulse strikes it, and strikes it in the direction in which the pendulum is moving, then the amplitude of the swing will be much larger than if the intervals of the impulse are not measured off in such a way. In other words, when the period of the impulses *is the same as* the natural period of the pendulum then the swing is largest. The impulses are said then *to be in resonance* with the pendulum.

The same effect will be produced if for the impulses we substitute a periodically but gradually alternating force, say a simple harmonic force, having the same period as the natural period of the pendulum.

Such a force when acting upon the torsional pendulum just described will continually increase the amplitude of the swing until the swing is so large that the work done during a swing against the frictional resistances is just equal to the work of the moving force during that time. From that point on, the pendulum will swing with constant amplitude. It is evident, therefore, that the larger *the amplitude of the moving force and the smaller the frictional resistances, the larger will be the amplitude of the swing.* But a large amplitude implies two things: 1st, A *large torsional reaction* in the suspension wire, and secondly, a *large velocity* whenever the pendulum passes through its position of equilibrium.

The bearing of this mechanical analogon upon the electric circuit having self-induction and capacity is very direct, as I shall presently point out. Let a simple harmonic E. M. F. $E \sin pt$, act upon such a circuit. I shall presently consider a complex harmonic E. M. F., and also circuits possessing Foucault current losses, and losses due to magnetic and dielectric hysteresis. They will form the last and in my opinion the most important part of my discourse. A simple harmonic E. M. F. acting upon an *elastic electrical circuit* in which the only frictional losses are those due to ohmic resistance will, when its period is the same as the natural period of the circuit, that is when *it is in resonance with the circuit*, continually increase the amplitude of the electric displacement, that is, the amplitude of the condenser charge and therefore also of the current, until the work done against the ohmic resistance is exactly equal to the work of the impressed E. M. F. From this point on the amplitude of the current will remain constant and equal to the amplitude of the impressed E. M. F. divided by the ohmic resistance. Or, to state it in terms which are more generally employed: *Capacity and self-induction neutralize each other when the circuit is in resonance with the impressed* E. M. F.

It is evident also that in a resonant flow there can be no difference in phase between the current and the impressed E. M. F., since in this case the current at any moment depends on the E. M. F. and the resistance, and on nothing else.

It is clear, however, that if losses due to Foucault currents, magnetic and dielectric hysteresis are present, then the current cannot be made equal to the ratio between the E. M. F. *and the ohmic resistance by any combination of capacity and self-induction, although, as a simple reflection will show, the difference in phase between the current and the* E. M. F. *may be educed to zero in this case also,*[*] *in which case we should have no false current, as it is generally called.* I shall presently discuss this point a little more fully.

(To be continued.)

The scene shifting in the new Opera House at Cleveland, Ohio, will be done by electricity. At present the Auditorium in Chicago is said to be the only playhouse in the world in which the scenes are shifted by means of electricity.

---

[*] Professor Duncan of Johns Hopkins University informed me yesterday that he deduced the same result in the course of an investigation, a short account of which he read before this Institute at its General Meeting in Chicago in 1892, "Note on some Experiments with Alternating Currents."—TRANSACTIONS, Vol. IX, p. 179.

The Physiological Effects of Electrical Currents of High Frequency.*

BY H. LEWIS JONES, M.D.

The application to medicine of electrical currents of great rapidity of alternations, or high frequency currents as they are commonly called, has occupied the minds of medical men to a great extent during the past twelve months. In France especially is this the case, where D'Arsonval has given much study to this difficult subject. The demonstrations which were given at the Royal Institution by Tesla in the spring of last year left an impression upon the minds of many people that enormous voltages were harmless to the human body if only they could be made to alternate with sufficient rapidity, and people were astounded at the spectacle of a lecturer placing himself in a circuit carrying a current alternating some hundreds of thousands of times per second, at a pressure of many thousands of volts. These experiments, coming not long after the accounts of the execution of criminals by electricity in America with pressures of 1,200 to 1,500 volts, and compared with the occasional notices in the newspapers of fatal accidents to workmen engaged upon electric light cables at 1,000 volts, made it seem as though the rapidity of alternation was the factor which protected Tesla from injury by the enormously high voltages which he was handling. The same view is taken by D'Arsonval in his papers before the Société de Biologie. He there describes an apparatus consisting of an induction coil supplying current to Leyden jars, the jars being made to discharge through a circuit including a helix of ten to fifteen turns of thick wire and an air gap. In this way there is set up in the circuit a succession of sudden rushes of current, which oscillate hundreds of thousands or even millions of times per second, the rate being determined by the Leyden jars; and the wire helix becomes the seat of electro-magnetic induction effects, comparable exactly to the induced primary currents of a medical induction coil, but very much more intense. These induced currents of the helix are the subject of D'Arsonval's experiments. By attaching wires to the beginning and end of the helix, the induced currents or extra currents can be held off; their energy was sufficient to bring to full incandescence a lamp requiring two amperes to light it, and it was therefore assumed that they had a magnitude of two amperes. The electromotive force of the currents was at least 8,000 or 10,000 volts, because they were able to lead across an air gap of several millimetres, and yet their effect upon the tissues of the body was very slight; in fact, they were hardly felt.

Now it is certain that a current of far less than 1 ampere, either steady or alternating 20, 50 or 100 times per second, would produce unbearable and dangerous shocks in its passage through the tissues; and the inference drawn is that the extreme frequency of alternation can render a current of dangerous magnitude innocuous. But I am not satisfied that such an inference is a proper one, for the following reasons:

1. A Leyden jar discharging through the body, produces effects which are painful and severe, as all who have felt them will agree; but yet this is a discharge of high frequency of alternation; in fact, it is by the Leyden jars in the circuit that the oscillatory character and the rapid rate of alternation of the discharge is determined. Oliver Lodge gives the rate of oscillation for a pint-sized Leyden jar at ten million per second; for jars of greater capacity the rate is less rapid.

2. The high frequency and high potential discharges of Tesla's apparatus are not altogether harmless, but can produce severe shocks and can kill small animals, as Elihu Thomson has shown. The discharges from the terminals of such an apparatus can produce severe muscular contractions even with the resistance of a considerable air space interposed in the circuit; so much so, that in some recent experiments which the writer was enabled to make through the kindness of Mr. Campbell Swinton, it was considered prudent to proceed no further with the experiment of actually touching both the terminals of the coil at once.

3. It is very doubtful whether D'Arsonval's estimation of the magnitude of the current of his apparatus is correct. The incandescence of a lamp filament with currents of high frequency has been recently under discussion in some of the electrical journals, and a very satisfactory explanation of the phenomenon has been forthcoming. It is well known that for alternating currents the resistance of a conductor is greater than it is for steady currents, and the increase of resistance rises rapidly as the rate of alternation becomes greater; and with frequencies approaching one million per second, the effective resistance of the lamp used by D'Arsonval would be raised enormously; this would require the energy needed to bring it to incandescence to be applied at a proportionally higher voltage, while the magnitude of the current would be lessened in an equal degree. For example, the energy of two amperes at 100 volts is the same in amount as that of 0.02 of an ampere (20 milliamperes) at 10,000 volts.

We are, therefore, able to say that the current which raised D'Arsonval's two-ampere lamp to bright incandescence was very much less than two amperes, and was probably only a few milliamperes, and herein lies the pith of the whole question. The experiments with high frequency currents of high tension are harmless if the magnitude of the current is small, and as the high potential is, in fact, obtained at the expense of the current, this latter diminished in proportion as the potential is raised by each successive step-up in the transforming apparatus. For the present, it may be taken as not yet proved that high frequency of alternation can render electrical currents harmless; and it may still be accepted that the effect produced by the passage of a current through living tissues depends primarily upon the magnitude of the current, as measured in amperes, which is made to traverse them, and upon its density or concentration therein.

A Telegraph Line in Africa.

The *Pall Mall Gazette* gives some interesting information in regard to the proposed telegraph line from Cape Cairo to an important point in the interior of Africa. Capital to the extent of £140,000 has been subscribed, and this is considered sufficient to construct the line as far as Uganda. The materials are now being ordered in London, and will be shipped shortly. The poles are to be of iron of light construction, in order to out-manœuvre the white ants, who would eat away wooden poles. From Fort Salisbury the line is to be carried to Tete, on the Zambesi, and from thence to Blantyre. There Consul Johnston will report the result of his surveys as to the best manner of proceeding on to Uganda, and the construction party will have to come to terms with the natives and the Arabs by subsidizing the chiefs and others of influence. There will be nothing in the way of impenetrable undergrowths or rank vegetation to contend with, as the line will avoid the low country and keep to the high plateau the entire distance. There are two alternative routes for the conveyance of the materials. There is good transport from the Transvaal to Fort Salisbury, or a shorter route would be adopted if materials were shipped direct to Beira, carried along the railway now being built as far as it extends, then conveyed the rest of the distance by ox-wagons. The scheme is being pushed forward with great activity now.

General Electric.

Suspicion Renewed by Last Week's Developments.

It Touches 58 1-2 on Sales of 11,000 Shares, July 12.

(*Wall Street Daily News.*)

This stock sold "ex-dividend" yesterday, and the way long holdings came out we should say it also sold "ex-confidence." It ranked third in point of activity, and sold down, dividend added, to 63¾. The price tells the story. If the millionaire directors had any confidence in the property, does it stand to reason they would permit a gilt-edged (?) 8 per cent. dividend paying stock to kick around at that figure? It is surmised that some one has been badly hit in this security, and that some out-of-town banks have been throwing it over.

(*The Daily American.*)

The insiders are still shouting vigorously for this property. They declare that it is earning 20 per cent. and will continue to pay annual dividends of 8 per cent. right along. Incidentally the company's treasurer denied that the suspension of the Chamberlain Land Company meant any loss to them outside of a few hundred dollars. The spectacle, however, of an 8 per cent. dividend payer like General Electric selling between 60 and 65 is rather unusual. There is a theory in Wall Street that when a stock behaves in the weak fashion that General Electric has behaved over a long period of time something inherently wrong must be the matter with it. It is argued that if the property is all right the stock is so cheap that insiders would buy it.

Active Material of Accumulators.

W. A. Boese has invented a process of preparation of active material for accumulators of some interest. It consists in mixing metallic oxides, such as oxide of lead, with sulpho-combined acids of anthracene and other organic compounds, and forming the mixture into plates. In practice, the metallic oxides are mixed with the residue of coal tar, transformed into sulphur combinations by extracting the petroleum ether, adding sulphuric acid, distilling the solvent and provoking the formation of the desired compounds. For the extraction of the residues of distillation, alcohol may be employed as solvent instead of petroleum ether, so that by mixing the product with the sulphuric acid and a metallic oxide (oxide of lead), the heat given off by the action of the acid on the alcohol is sufficient to provoke the chemical action on the hydrocarbons at high molecular weights contained in the alcoholic extract, without recourse to external heat. According to the inventor, the plates obtained by this process acquired great stability in consequence of the agglutinative properties of the salts when mixed with anthracene-sulphonic acids or their analogues.—*Review Industrielle.*

The State Board of Railroad Commissioners has sent a circular to every street service railroad in the State recommending that every car operated by the electrical trolley system in this State on a double-track line be equipped with gates on both ends, and that only one gate, that opposite the other track, on the rear platform, be open for the ingress and egress of passengers; also that no person (except an instructor, when necessary) be allowed to ride on the platform with the motorman on an electric car. The board also recommends that on all open cars operated by the electrical trolley system on double tracked lines there shall be attached a guard on the side of the car next to the opposite track, running the entire length of the car, to prevent passengers entering or leaving the car on that side; this guard to be of such a nature that it may be transferred from one side to the other.

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:
6 Park Place - New York

CHICAGO:
J. F CONNOR, - - 823 Monadnock Building.

BOSTON:
W S. KEY, - Room 34, 620 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Electrical Engineering Practice. It is not to be denied that the conservatism which has been characteristic of the introduction of electricity in Europe, and especially in England, has been productive of some good results in the way of engineering practice which the pioneer work on this side of the Atlantic lacks, but American enterprise must be credited with having set the example and furnished the experience which have been the basis of the industry, to which European engineers have added many practical refinements.

The history of the electric light is an illustration of this fact; and judging from the agitation of the electric railway question in England, history promises to repeat itself in this branch of the science.

In the case of incandescent electric lighting, which was only introduced about eleven years ago, the progress of its adoption in this country was without a parallel in any other new industry, and central stations were established in several hundred cities before the subject was seriously considered abroad. The foundation which was laid in this country, however, for the business of electric lighting was of the greatest service to our conservative neighbors, who, profiting by the experience already gained, eventually constructed some of the finest stations in the world from an engineering standpoint. Having decided upon the work with great deliberation, the details of these plants were worked out with the object of producing permanent, solid and efficient systems which may be considered as types of the best practice in electrical engineering.

This class of work is now becoming the rule in most of our large cities, but previously it had been customary to install the cheapest kind of stations possible, with the idea, which was not without reason, that the best system would soon become out of date owing to the improvements which are being constantly made.

This argument is often advanced even at present as an excuse for the construction of cheap stations and lines, but if the case is considered carefully, there is but little reason to warrant such an opinion. The conversion of mechanical into electrical energy is accomplished by most of the standard dynamos with a loss of only about ten per cent., and with large machines under favorable conditions of load it is even less, while the line losses may be fixed at the most economical figure with precision. In the electrical part of the plant the efficiency is very close to the highest possible, while it is in the boilers, engines, shafting, etc., the chief losses occur. For this reason any possible future improvements in the dynamo can only increase the efficiency of the plant by a very small fraction, while on the other hand thorough mechanical engineering can effect a much greater saving in the design and construction of the steam plant. The building of cheap steam plants and lines has invariably proved a shortsighted policy which has been dearly paid for in depreciation and repairs within a short time. There is no question but that in the end a well built plant is the cheapest.

In electric railway work, as with electric lighting, the system was worked out and put in practical operation all over this country before it was attempted abroad. Nearly every town here of any size has its electric railway, while in England the subject has just begun to be agitated now—about five years after the business has been thoroughly established on this side. Having finally awakened to the consideration of electric traction, however, the subject is being investigated with thoroughness, and there is a possibility that eventually foreign work may bear the same relation to ours in this line as it has in electric lighting.

The trolley, the conduit and the storage battery are all being carefully investigated, and in a methodical and businesslike way which is likely to produce substantial results, while the experience gained from the work already done here will figure largely in determining the best methods to pursue.

Americans have certainly taken the lead in the practical applications of electricity, but in many respects we have been surpassed by foreign countries in the nice engineering details which go to make up the most perfect systems. Having devised an operative plan there has been a tendency here to stop at that and leave the perfecting of the details to others. The expense and trouble caused by crude engineering work are being appreciated in many cases, and the tendency is at present towards greater refinements in workmanship and engineering practice.

……o……

Through by Lightning. There have appeared several inconsistencies in the various descriptions of the Chicago-St. Louis electric railway scheme some of which were noted in ELECTRICITY of June 8, 1892, on occasion of the first official announcement of the project in a lecture by Dr. Adams before the New York Electric Club.

Quoting from the report mentioned we find the following:

"He (Dr. Adams) said that at the present time there were 1,200 through passengers carried daily between the two cities. It was estimated that 30 million people would visit the World's Fair. Ten per cent. of these would use the road for curiosity alone. At $5 per round trip this would bring in 15 million dollars. The road would cost to construct but 6 million dollars."

Apropos of this we find the following statement given by Dr. Adams to a St. Louis paper under date of July 7, 1893, just thirteen months after the lecture mentioned:

"There is one mistake that I wish you would correct," he said. "It has been reported time and time again that we expect the road to be completed in time for the World's Fair. Now you won't find a single intimation in our prospectus or any of our advertisements, that we made any such promise, and we never had any idea of it. In our contract with the General Electric Company they guarantee to put in motors which will give a maximum speed of 100 miles an hour. Everything is moving along well, but I decline to say when the road will be completed, as that is still an uncertainty."

With the conclusion of this statement we heartily agree, but a comparison of the two certainly shows a discrepancy in the utterances of a year ago and now which it will be difficult for any one not financially interested in the road to reconcile.

Another point which is apparently in need of official harmonizing is in regard to the contract with the General Electric Company for supplying all the machinery, which was closed only a few weeks ago, and the statement in the railroad's prospectus, printed a year ago, that "the construction of motors has already been commenced."

Has the aspect of this scheme changed so materially that the plans and promises of a year ago have been not only ignored but forgotten?

……

Sunday. The decision of the World's Fair management that hereafter the entire Fair shall be closed on Sundays marks the end of what was in the beginning an entirely unnecessary controversy.

It is to be noted that no religious or moral awakening has struck the rulers of the Fair, either in their individual or corporate capacity. They have simply learned that it does not pay in dollars and cents to open the gates on Sunday.

The fact that it would not pay to run an enterprise of this nature in this country on Sunday had already been well demonstrated, but the management seems to have ignored the lessons of past experience. They knew that Sunday theatrical entertainments paid in Chicago, and doubtless thought that out of the hundred thousand visitors in town enough could be added to local patronage to make a success of Sunday opening. But it seems that a stay of a week or two in the city has not proved enough to Chicagoize any great number of visitors.

The most potent factor, of course, in the failure of the experiment has been the action of the exhibitors themselves, hundreds of whom have refused to uncover or show their exhibits on Sunday. And it is worthy of special notice that a large number of the exhibitors who have taken this action, if not indeed a majority, are representatives of Continental Europe, where a great many people would have us believe there is no such day as Sunday as we understand it.

It is one of the strongest arguments in favor of the Christian religion that the lives, habits, and thoughts of all of us, whatever be our professions, are molded and shaped to a considerable extent by the teachings of that religion.

Probably not 50 per cent. of the exhibitors who have refused to open their booths would claim that Sunday opening was a moral wrong; it was simply their habit to make Sunday a day of rest, and they believed it to be a correct habit.

……

We note with pleasure that the Detroit Lighting Commission has adopted the suggestion made by Electricity and appointed Mr. F. B. Rae and Prof. H. S. Carhart as consulting engineers, to assist Mr. Alexander Dow in the work of locating and installing the municipal lighting plant. The suggestion was dictated by wisdom and common sense.

No Time To Be Asleep. Electricity has already pointed out the desirability of securing an investigation by a Congressional Committee of the plan of organization and methods of doing business of the Electric Trust. Some of the paragraphs we have printed on this subject have been regarded by the officers of the Trust as *prima facie* evidence of malice.

We are willing to let the charge of malice go undefended for the time being, but we again urge the investigation.

Congress will soon be in session, and though an Investigating Committee might not get to work before late in the fall, there is no time to lose; and every independent manufacturer will use good judgment in presenting the facts in the situation to his Representative in Congress.

Immediate action is all the more imperative because of the plans of the Trust to begin work at once, through the recognized channels for such work, to secure an extension for the Edison lamp patent.

Although the price of Trust shares may point to an early dissolution of the illegitimate enterprise, independent manufacturers should not be caught napping, and we urge the wide circulation of petitions to the various Representatives, asking for immediate attention to this subject.

Blank forms, ready to fill out, will be found on the last page of this issue, and extra blanks will be supplied in any number upon request.

……

Put On a New Driver. Roguery in horse racing is proverbial. In running races it is almost impossible of prevention, chiefly because the condition of the horse is not a demonstrable fact. You cannot tell whether he is fit or not.

But in the trotting races as conducted on the Grand Circuit crooked work has been well nigh eliminated. A dishonest driver may pull his horse for a single heat, but the mere suspicion that he is doing so usually results in a new driver being put on by the judges, who are experienced men and rarely make a mistake.

This rule of trotting horse racing could be well applied just now to the General Electric Company.

The public were led to put a good deal of money on this company in its race against the field, and were largely influenced in so doing by the high standing of the gentlemen who compose the Board of Directors. They are now almost universally convinced that the race is not being properly driven. Some charge crookedness, but a great many believe it is only lack of ability.

The company has declared its regular quarterly dividend of two per cent., and published a statement claiming that it has earned it and a small surplus besides. Still the common stock lingers around 60, and both preferred stock and bonds are away below par.

If the public had any degree of confidence that these statements were correct and honest, not even a stringent money market could prevent a boom in the stock.

The Directors should yield to public opinon, and put on a new driver—a man who has no interest whatever in the stock market, either in keeping it down or putting it up.

If the company can win, the public wants to know it before it sacrifices any more stock at a loss of $55 per share. And nothing can convince the public except a report made up by a committee of stockholders—a report on volume of business done, on the value of assets and the actual liabilities—such a report as the present management has never dared to print.

……

The following may be understood as an open letter, and the answer to our inquiry, if any, will be printed in these columns:

To Captain Eugene Griffin,
Vice-President of the General Electric Co.

Dear Sir: Were you not endowed (temporarily, at least,) some months ago with prophetic vision, and did you not dispose of the greater part of your holdings of General Electric stock at about 109?

An early reply would no doubt interest other, and perhaps less perspicacious, stockholders.

Yours, with commendations,
Electricity.

……

Nothing would so quickly restore confidence in Electric Trust stock as an authentic and bona fide statement showing that the volume of business has been more than, or equal to, the combined business of the Edison and Thomson-Houston Companies for the last year previous to the consolidation, and that selling expenses have been reduced. It is our belief that such a statement cannot be honestly made or else it would have been given out long ago.

……

Several months ago a gentleman well known to Electricity invested a little over $50,000 in General Electric at 101. He did so on the advice of the strongest banking house represented on the Board of Directors. The money belonged to an estate of whose funds this gentleman was the guardian, and he is one of the many people who have an acute interest in learning whether the respectable members of this Board knew what they were talking about or whether they also were deceived.

……

Any statements of profits given out by the Electric Trust are absolutely valueless until it is known how those statements were made up. The rule in vogue with the Thomson-Houston Company was to take the difference between shop cost and selling price and call the amount profit, ignoring the cost of doing business. Large profits are possible in any manufacturing business when computed in this manner.

……

All visitors to the World's Fair will be welcome at the booth of Electricity, Section Y, Northwest Gallery, Electricity Building.

The Canal Electrical Experiments.

Supt. Hannan has given notice that all experiments with electricity on the canals must be completed before the first of October next. All traction systems must be operated on the berme bank and the experiments will not be permitted to interfere with navigation. That portion of the Erie Canal from the Monroe avenue lock, in Rochester, east to Fairport; and also that portion of the Erie Canal between lock No. 2, at North street, in Albany, and a point three miles north, have been designated for the preliminary tests.

Electrical Congress Programme.

Resumé of Opinions and Suggestions Expressed in Reference to the Report of the Sub-Committee on Provisional Programme and to the Decisions of the Forthcoming Congress at Chicago.

Opinions have been unanimous in favor of leaving unchanged the values of existing practical electrical units as already adopted by past Congresses.

It has been pointed out that the definition of the mean intensity of an alternating current adopted by the Paris Congress of 1889 is incorrect as stated and calls for a slight amendment by way of explanatory addition.

It is generally admitted that an international unit of illumination is in practical demand. The unit proposed in the report, namely, the illumination of a bougie-decimale at the distance of a metre, has been well received, except in Germany, where a sub-standard unit of illumination based upon the Hefner-Alteneck lamp has been favored.

The definition of the concrete standards of the practical units, as recommended in the report, and taken from the Report of the British Board of Trade Committee on Electrical Standards, has met with general satisfaction. In regard to the ohm it has been suggested that the definition shall be regarded as final from a practical point of view, and that whatever slight discrepancy may be discovered in the future between this and the best known approximation to the true ohm shall not affect the practical concrete standard, whose formal specification might be worded and denoted accordingly.

The retention of the terms ampere-hour and kilowatt-hour has been universally favored.

The introduction of a practical unit of conductance has met with favor, and the name mho for this unit has only met with opposition in Germany on the plea of unclassical treatment of a name held in universal respect, the name "thomson" being advocated as a substitute.

The recommendations of the report in reference to the new practical magnetic units has given rise to considerable discussion and difference of opinion. It has long been contended in English technical journals that the practical computations of electro-magnetic machines based upon C. G. S. magnetic units, introduce burdensome coefficients, such as 10^8, with inconvenient frequency, while to fill the needs of a system of nomenclature, names for magnetic units in such computations have been improvised and employed provisionally. The German proposals, have, however, been to retain the C. G. S. units and without names for them. In France the same difficulty of framing a practical system of magnetic units into a thoroughly convenient and harmonious series has elicited a dissension as to whether any or all of the units recommended in the report should be adopted. A Canadian suggestion has been made to adopt the units of flux and flux density as proposed, but to make the ampere-turn the practical unit of M. M. F. and alter the unit of reluctance in the ratio of $\frac{1}{4}\pi$ to correspond. Aside from the difficulty in agreeing upon the values of these magnetic units, the names recommended for them in the report have been generally well received, the term oersted perhaps excepted.

The adoption of the term henry for the unit of self or mutual induction has met with general consent. Difference of opinion has, however, been manifested with regard to the name of the quantity whose unit it denotes, the term inductance having been employed in France to denote product of a self induction by an angular velocity, while in England and in America writers have been divided, some employing it in this sense, and others, perhaps a majority, with the meaning given in the report, of a coefficient of self induction, or mutual induction, simply.

The suggested definition and introduction of the term inductivity has been disfavored, and the definition for "impressed E. M. F." has been generally considered unnecessary.

The definition of the value of Matthiessen's standard of conductivity has met with opposition in France and Germany as being of national rather than international importance.

The definition of the north pole of a magnet has not been opposed, but it has been pointed out that in the definition recommended in the report the word "terrestrial" might replace the word "geographic" with less danger of ambiguity.

The definition of alternating current systems as simple, diphase, triphase, or polyphase, has been favorably considered in all but the wording of the proposal. It has been suggested, however, to consider any non-simple alternating system as a polyphase system.

The use of the term voltage has met with favor in England, but with disfavor in France and Germany.

The terms "transformer" and "dynamotor" in place of "convertor" and "continuous-current-transformer" have not been opposed, except as being somewhat beyond the scope of an International Congress. The more universal use of the term kilowatt in place of the term horse-power has only met with disapprobation in England.

In France and Germany objections were made to some of the terms suggested, on the ground that they were specifically English.

The more universal introduction of the metric system of weights and measures has met with general favor.

Strong recommendations have appeared in favor of an international system of symbols and notation for electric, magnetic and physical quantities generally, with a corresponding revision of the existing system of electrical and physical nomenclature. The system of notation advocated by M. Hospitalier, and generally recommended in the report, has not elicited adverse criticisms except in the case of a few of the symbols suggested.

In conclusion your Committee submits the view that considering the very debatable nature of the subjects forming its report, the variety of opinions formed in different countries and expressed under different interests, the reception of the report has been remarkably favorable, and appears to have attained the desired object, namely a concentration of general opinion toward a consensus in aid of the forthcoming Electrical Congress.

Carl Hering, Chairman.
A. E. Kennelly.

Aerial Navigation Congress.

There will be a conference at Chicago on aerial navigation August 1 to 3. The local committee is composed of engineers and scientists who have made an effort to elicit papers from scientific writers and experimenters throughout the world. The secretary, Prof. A. F. Zahn, of Notre Dame, Ind., has received valuable papers describing the recent experiments of inventors in several countries. Among the contributions are photographs and descriptions of several successful steam flying machines and of the great military balloons of twelve different nations.

Business Troubles.

The Giant Electric Motor Company of Portland, Me., has gone into insolvency.

Jerome Redding & Company, electrical engineers, 48 Hanover street, Boston, have assigned to Ralph W. Foster.

BOOK REVIEWS.

The Law of Incorporated Companies. By Allen R. Foote and Charles E. Everett. Published by Robert Clarke & Company, Cincinnati, O. Three volumes, octavo; 3,000 pp. Price, $15.00.

The discussion of the basic principles of economic legislation in regard to franchise companies, such as gas, electric, telephone, railway, etc., is deduced in this book from the fundamental relations existing between the individual, the municipality and the State, the aim of the authors being to establish a general and clearly defined policy for the regulation and control of industrial corporations which shall protect public rights without unnecessarily checking the growth and privileges of corporations. In addition to this the work also contains a very complete resumé of the laws governing corporations in each of the States, with over 4,000 citations of cases and decisions, each State being represented by a resident attorney. The scope of the book has required an editorial staff of forty-eight writers whose work has extended over three years. A very full analytical index of the entire work is arranged with special reference to the ready comparison of the provisions of law of each State upon any given point, and brief sketches of the attorneys engaged in the preparation of the work are given.

The plan of the book is unique in many respects and the discussion of the economic principles which are involved in the operation of franchised companies supplying public services must be considered original and ingenious even by those who question the authors' conclusions, which are certainly radical enough to provoke the discussion on this subject which the book invites.

In outlining a general policy for the government of the class of corporations mentioned above Mr. Foote commences with natural laws and the physical and moral standards which are universally recognized as the ideals upon which legal enactments are based, and proceeds to define the rights of the individual, municipality, State, etc., and their relations to property and industrial corporations.

The author concludes that as the State is the creator of the corporation it should therefore exercise sovereign power over it, and this control should be entirely out of the hands of the municipality in which the corporation is doing business as control by interested parties must be incapable or unjust.

In regard to franchises for companies supplying public services, it is claimed that to most effectively supply such services under the most economical conditions franchises should be exclusive, perpetual and untaxed, but should contain stipulations as to charges for services, method of keeping accounts, rate of dividends, disposition of surplus or deficit, etc., all to be under State supervision. The issue of stocks and bonds is also to be under State supervision and the amounts issued to be limited to the actual investment, the object being to make such stocks equal to Government bonds as securities. The right of the State to prescribe the apparatus to be used or to specify the best apparatus of its kind known is also advocated.

Municipal plants are condemned as being the most effective barrier to the progress of manufacture and invention, although aside from the actual investment corporations under this plan would practically be run by the State, which would assume the greater part of the duties of the companies' officers as they generally exist to-day.

The plan outlined as ideal seems rather too utopian to be easily put in practice, and if attempted would require an additional State Department of most unwieldy proportions.

Following this general discussion comes the resumé of the laws of each State arranged under the same sub-divisions as in the general discussion, and this part of the work is not only a very complete digest of the law of each State, but furnishes an excellent method of comparison of the laws of the different States on these subjects.

The book therefore constitutes a standard work on the laws of franchise companies, and suggests a useful field of study in the direction of a general policy for their regulation.

It is the intention of the editors to keep the work abreast of the times by issuing annual volumes in which all changes in State constitutions, Legislative enactments, court decisions and municipal policy regarding the class of subjects dealt with will be fully reported in a section or each State, covering the year of issue.

THE ELECTRIC TRANSMISSION OF INTELLIGENCE, AND OTHER ADVANCED PRIMERS OF ELECTRICITY. BY EDWIN J. HOUSTON, A.M. New York: THE W. J. JOHNSTON COMPANY, LIMITED, 41 Park Row. London: WHITTAKER & COMPANY. 1893. 330 pages. 83 illustrations. Price, $1.00.

The third and concluding volume of Prof. Houston's "Advanced Primers of Electricity" is devoted to the telegraph, the telephone, electrolysis, electro-metallurgy, the storage battery, electric welding, electricity in warfare, electrotherapeutics, electric annunciators and alarms and several miscellaneous applications of electricity.

The primers on multiple and cable telegraphy and telephony will be particularly appreciated by those who have had no previous knowledge in electricity, as the author places these subjects in such a light as to make them easily understood by any reader. The quadruplex and other systems of multiple telegraphy, as well as the principles of cable and time telegraphy, need not remain mysteries to the general public.

The other subjects are handled in the admirable and lucid manner that characterizes the writings of Prof. Houston, and his recent election as President of the American Institute of Electrical Engineers shows that his electrical attainments are appreciated by the electrical profession.

The extracts from standard authors at the end of each primer form a feature that has been highly praised in the preceding volumes and has been retained in the present one.

Each primer is, as far as possible, complete in itself, and there is no necessary connection between the several volumes of the series, of which the present one is the third and last.

One Trust a Failure.

How the Archer & Pancoast Company Was Wrecked.

(G. Wilfred Pearce, in American Industries.)

"Have you noticed that Mr. Clement M. Biddle, of Philadelphia, who is a prominent member of the Manufacturers' Club of that city, has made an inglorious failure of the Gas and Electric Fixture Trust which he organized in 1889. The trust included nearly every fixture factory in the United States, and its first act, after completing its organization, was a new price list, which advanced goods 40 per cent., and no dealers were permitted to buy trust goods unless they would swear not to buy of the three firms not members of the trust. The salaries paid to the principal officers, none of whom were practical fixture makers, were extravagantly high. . . .

"The wages of workmen were not advanced in any case, and in many departments of the factories highly paid labor was supplanted by cheap labor taken from the cotton mills of New England. Many small factories were forced to suspend because the trust people threatened to boycott makers of supplies who sold to the small manufacturers. Plumbers who sold goods at less than prices regulated by the trust were black-listed for one year after offending. A number of alleged patents without which the trust said goods could not be made were bought up by the trust, and dealers or makers who did not understand that the patents were worthless were induced to sign the trust agreement for a fixed period.

"For two years all went well, and then many makers of brass goods who had not made fixtures went into that line, simply because at trust prices there was a large profit to be made. When this competition became powerful, the trust lowered prices and bankrupted several firms in its own ranks, and did not hurt the outsiders, who were not weighted down by enormous fixed charges and assessments which trust firms were compelled to pay. A few weeks ago the Archer & Pancoast Manufacturing Company, New York, an old established firm and members of the trust, assigned, and their statement to creditors is a remarkable one, as it shows that its factory has been run full time for years on goods which averaged 25 per cent. profit. It has made no bad debts. Its business has been well managed by men of character and ability, yet it owes $500,000. This whole sum is debts to banks, floated by Mr. Biddle of the Manufacturers' Club in a vain attempt to raise money to crush out rivals in trade and spent in buying out competitors at high prices."

Personal.

Mr. J. H. Rhotehamel, President of the Columbia Lamp Company of St. Louis, who is in New York this week, wishes it to be thoroughly understood that the bond filed by his company furnishes absolute protection to New York purchasers of Columbia lamps.

He Had the "Idee," but the Lesson Was Lost on Him.

It is perhaps natural that people who are unacquainted with "electric propulsion" should feel curiosity as to how the trolley pushes the car, and it is just as natural for a good many persons to find their curiosity about electricity remain unrelieved after the thing is explained to them, as was the case with the elderly person who figures as "an anxious inquirer" in the following dialogue which the Chicago *Tribune* furnishes:

An old man from somewhere beyond the suburbs stood yesterday on a Forty-seventh street corner watching a trolley car moving swiftly eastward with a heavy load of passengers.

"That's one of these 'lectric cars, ain't it?" he said turning to a bored-looking man who was leaning against a telegraph pole.

"Yes."

"I don't see how 'lectricity can make a car full o' people flip along over the ground like that."

"You don't?" exclaimed the other, becoming interested. "Why, it's easy enough to see through when you once understand it."

"I 'xpect so, but I've never heard enough about it to understand it."

"It is all a matter of watts. A watt, don't you see, is a fraction of a horse power, expressed in the technical language of electrical engineering. You know what an ampere is, don't you?"

"A what?"

"An ampere. It is a quantity of electricity that goes through the wire and develops the watt. The electricity comes from the central dynamo through that wire you see running along overhead, runs down through that iron pole and goes to the motor, which is an ingenious but perfectly simple arrangement of wire coils with a revolving frame acted upon by the current which sets it to spinning, and thus puts in motion a small cog-wheel that engages another cog-wheel that communicates the rotary movement to a third cog-wheel fastened to the axle of the car. It is as plain as day when you get the idea."

"Yes, but how"——

"Don't you understand it yet? There's a sort of wire brush that presses against a copper plate connected with the motor, and the wire is wound on the frame I was telling you about, so that when the current enters the motor it can go either way, and part of it goes one way and part the other, so that the pressure is applied in opposite directions and that's what makes the jigger revolve and sets the wheels in motion. The current goes back through an underground wire. See through it now?"

"Y-yes, I think I kind o' get the idee."

The affable stranger strolled down the street and the old man took another look at the overhead wire, gazed earnestly in the direction in which the car had gone, took off his hat and wiped his forehead.

"What I'd like to know," he muttered, "is how in thunder the electricity makes the car go!"

In Canada tests are being made in operating lock gates on the Soulanges Canal by electrical power. If successful there the plan will be generally adopted on the canals.

Mr. Edison says there is more money made out of little discoveries than big ones, and that it is better to keep the secret of an invention than to have it patented.

Current Items.

At Brewsters, N. Y., an apparatus has been set up for disposing of sewage by the aid of electricity. The plant comprises a fifteen horse power engine, a twenty horse power boiler, a dynamo and two vats, one holding 1,000 gallons and the other 3,000 gallons. The frame structure in which the concern is placed covers an area of 23 by 30 feet. An iron cistern outside the building stores the water demanded for the steam boiler and other purposes. The vats in that building are used for the electro-chemical treatment of the sewage. One receptacle serves for the mixing of the chemicals with the deposit, from which a pipe conveys the compound to the other, in which there is a combination of electrodes that agitates the mass and also conducts a current through the solution with the immediate effect of deodorizing, disinfecting and vaporizing the offensive accumulation. The action in the vat is similar to a violently effervescing spring.

The second assistant examiner in the Electrical Division of the Patent Office is a former Connecticut school teacher, Mrs. Sarah J. Noyes. Appointed in 1881 she has witnessed an enormous growth in the science of electricity, and has become so proficient in her duties that it would be difficult to fill her place were she to retire. In the examination of patents she brings to bear a remarkable general and technical knowledge of all the inventions in which electricity is a feature.

The telegraph operators have become such a numerous body in this country that there is at the present time a large surplus of idle help in the business.

Since the electrical cars in Brooklyn have driven the horse cars into retirement and dispersed the horses, the rats that were so luxuriously domiciled in the forage and rationed from the grain stored in the immense stables are seeking new habitations among the dwellings in the neighborhood and the trade in traps has become lively.

One of the most remarkable illustrations of progress in electrical appliances is electrolytic painting. Hitherto, if copper or other metal had to be deposited electrically, a bath of solution was needed. Now all this is changed, and a ship's hull can be plated as easily as a spoon or teapot. Instead of a bath, insoluble salts, ground to a fine powder and mixed with water, are used. This mixture is painted on the metal to be plated by a fine wire brush, to which one pole of a dynamo conductor is attached, the other pole being connected with a plate. Not only pure metal but all sorts of alloys can be used.

Among the proposals for constructing a submarine boat opened recently by the Navy Department at Washington, one of the two that seemed to meet most fully the requirements of the department treated of the invention known as the Baker boat, which uses steam as the propelling power when on the surface and electricity, supplied by storage battery, when submerged. The essential feature of the Baker boat is the propelling apparatus, which also serves to submerge her. This consists of two screw propellers, one on either side, so arranged on a transverse shaft passing through the middle of the boat at the centre of gravity that they can be turned at different angles. When the boat is to be submerged these propellers are turned upward and drive the hull under water, and when the desired depth has been reached the angle is adjusted so as to drive the boat along in a horizontal line. The boat is designed to make a speed of twelve knots an hour above and ten knots under water.

The Pennsylvania Railroad Company intends to increase its facilities of communication by the the addition of a long-distance telephone to its already superior system. The important points on the lines will be brought into close call by the new scheme, and a great saving of time will be the result. The long-distance line is intended for the exclusive use of the high officials of the Pennsylvania Company's system.

Brussels and Antwerp are both to have international exhibitions in 1895, and expect to be connected by electric trains running 110 miles an hour. These cities are twenty-five miles apart.

In a recent interview, Secretary Rankine of the Cataract Construction Company, Niagara Falls, explained the delay in letting the contracts for the machinery as follows: "We are as anxious as anyone to push the work along," said Mr. Rankine, "and we are doing so. The letting of contracts for electrical machinery is not a matter that can be done in a day. It is a big work and an expensive work. In a measure, the building of such large machines is experimental, and it is but natural that the company should want to be absolutely certain that each step it takes is the wisest."

In one branch of the London Post Office last year the absences through sickness diminished two days per employee. This is attributed by the chief engineer, Mr. Preece, to the purer air caused by the substitution of electricity for gas for lighting purposes.

The four countries in the world which possess the smallest telegraphic facilities are Peru, Paraguay, Uruguay and Persia. In Paraguay only 510 miles of wire are in operation, requiring the services of but twenty-eight persons. Peru has thirty-six offices and 1,600 miles of wire.

The Astronomer Royal (W. H. M. Christie) gave evidence before the Parliament Commission of Inquiry at London as to the disturbance caused to the instruments at Greenwich Observatory by the City and South London Railway. He said that the Observatory was about five miles from the railway. Two circuits of wires at right angles to each other and connected with earth plates had been established for recording the electric currents passing through the earth. The plate nearest to the railway was two and a half miles distant. Towards the end of 1890 certain anomalous disturbances were noticed on the recording instrument. They all occurred between 7 A. M. and 11 P. M. on week days and ceased on Sundays. In March, 1891, the disturbances began on Sundays also, but not till 1:30 o'clock. It was ultimately found that the disturbances corresponded with the hours of the passage of trains on the electric railway. They amounted to from one-third to half a volt in difference of potential between the two earth plates of the circuit. The disturbances in the two circuits, one of which was nearly parallel to the railway, were approximately the same. Owing to these disturbances it was no longer possible to trace by the Greenwich instruments the diurnal variations of the earth currents.

Boston Notes.

The subject of electric cars continues to agitate the public mind a good deal in the city of Cambridge. Now that the State Legislature has declined to grant the petition or pass the bill recently introduced by the promoters of a storage battery railway project, the West End Railroad Company is seeking to extend its electric system in the University City. Prejudice, however, is strong out there, and a good deal of work is having to be put in by the city aldermen and other local bodies having in mind the conciliation of all parties in interest. So exclusive are the residents of some of the streets in the vicinity of Harvard University that on no account will they listen to any proposition for the laying of tracks on those particular thoroughfares.

Through the munificence of an eccentric man of wealth, who died many years ago, Tufts College, Mass., is to have a new scientific and manual training school for students of both sexes. The property left for this purpose has appreciated in value, so that it will be possible to erect and equip a very fine building for the above purpose. Some of the ablest and most successful engineers in this country have been educated at Tufts College, Professor Dolbeare, the accomplished and widely known scientist, being a member of the faculty.

The sudden drop in General Electric stock last Tuesday, the same falling from 70 to 58½, with a slight rally, set the financial world in and around Boston by the ears. The report that several hundred men had been laid off at the Lynn factories, coupled with the rumor that the executive offices are to be removed from Boston to New York, evidently caused a scare, which was not unreasonable seeing that there was some truth in both reports.

Work on the electrical equipment of the Lynn and Boston Railroad is being energetically pushed all over the system, the Marblehead section being expected to be in full running order by August 1. The company is introducing an air brake on its cars which gives great satisfaction. Other novelties are also being introduced on all new cars as they are built and put into service. High class concerts under the auspices of the company are given at Nahant Beach every evening which draw large crowds and so furnish good traffic for the road. The Thomson-Houston Electric Band is a great attraction, being composed of first-class musicians, all of whom are employed in the factories of the General Electric Company.

An exciting piece of business is under way at Manchester, N. H. The city council is confronted with a suit in the Supreme Court, instituted by some of the most prominent citizens and heaviest taxpayers in the city. The city council peremptorily broke a three years' contract that it had made with the Manchester Electric Light Company at a special meeting called ostensibly for another purpose, and made a new contract for ten years without giving any other company an opportunity to bid or issuing the customary call for bidders. The electric company, also a local concern, complains that if given a chance to bid it could save the city $100,000, upon which information a strong petition was prepared asking for an injunction to prevent the first named company from executing any part of its new contract. The ablest counsel in the State have been engaged to fight for the citizens, excitement runs high, and a bitter contest is fully expected.

The Boston Light Company and the Edison Illuminating Company are seeking to restrain Mr. A. W. Perry, who owns a private electric lighting plant with which he does commercial lighting, he having leased the plant for that purpose from the first named company, from extending his business. It is contended that Perry's contract forbids his doing any more business than a specified amount, yet he has suspended additional wires for purposes of extension. The Edison Illuminating Company's complaint is that Perry's lease is of no account as the Boston Electric Light Company had no right to farm out or lease part of its franchise. Perry contends that he is being made the victim of a conspiracy and he is to prove it in his defense which he is now preparing. The State Board of Gas and Electric Commissioners has the case in hand.

General News.

What is Going on in the Electrical World.

Baltimore.—The John Street line of the City Suburban road is being changed into an electric line.

Hartford, Conn.—Both branches of the city council have authorized the Horse Railway Company to use the storage battery.

Plainfield, N. J.—Work on the electric road to North Plainfield has been resumed and will be pushed so as to complete the road as soon as possible.

Kansas City, Kan.—The Consolidated Electric Light and Power Company has sued the city for $22,019, the amount due for electric light service from May, 1892, to July, 1893.

Amsterdam, N. Y.—The Amsterdam Street Railway Company has been granted a franchise to build and operate an electric railway along the Mohawk turnpike to Fort Johnson.

Lansingburgh, N. Y.—This village is still groping its way in the meagre light of gas lamps, but the more enterprising citizens are promoting a movement in favor of electric lighting.

Chatham, N. Y.—The electric light plant has been sold at sheriff's sale to satisfy a judgment of $11,732 held by the General Electric Company of New York. The purchaser paid $4,000 for the plant.

Staten Island, N. Y.—The trustees of the village of Edgewater have awarded the contract for lighting the streets to the Electric Power Company of Staten Island at the rate of $17.50 per lamp. This is an increase of $2.50 per light per annum.

Sioux City, Iowa.—A. M. Coffman has sold his controlling interest in the Leeds Electric Railway to Otley Darlington, of Philadelphia, who was elected president of the company on the resignation of Mr. Coffman as soon as the sale was effected.

Frederick, Md.—The managers of the Chesapeake and Ohio Canal propose to abandon the mule and adopt electricity as a motive power on their waterway if the experiments on the Erie Canal result in the discovery of a practical electrical system.

Indianapolis, Ind.—The Chicago and Central Indiana Electric Railway Company has placed an order for 500 miles of steel rails. The road seems to be an assured fact, and will run through Noblesville, Frankfort and Lafayette. The main shop will be at Noblesville.

Atlanta, Ga.—The proposed electric line from Atlanta to Salt Springs will be built as speedly as possible. It will be twenty miles long. The officers are: Henry Camp, of Covington, Ga., president; Thomas Camp, secretary and treasurer, and B. F. Curtis, general manager.

Bar Mills, Me.—Bids for building the roadbed, overhead construction and electrical equipment for the proposed electric railroad from Bar Mills to Bonney Eagle, along the eastern shore of the Saco River, will be called for as soon as the specifications, now in preparation, are finished.

St. Augustine, Fla.—The electric lighting equipment of the Ponce de Leon Hotel has been completed. Over 40,000 feet of wire was used, supplying 1,000 incandescent lights. The Alcazar, the Casino and the Royal Ponciana will also be fitted with the latest improvements in electric lighting.

Montreal, Can.—The municipal council of Coteau St. Louis has passed a by-law granting a franchise for thirty years to the Montreal Street Railway Company. Work will be begun at once and the company expects to have electric cars running to Amherst park, via Carriere road, within thirty days.

Montgomery, Ala.—Judge Arrington has confirmed the sale of the Cloverdale Electric Street Railroad, and the consolidation of the Cloverdale and Terminal lines followed. There will not be any change for the present, but before long the entire Terminal line will be equipped with electricity.

Denver, Col.—All of the cable lines on the Tramway system have been transformed into electric lines. As the cables wore out, the company have been substituting electricity rather than purchase new cable material. They found electricity to be more economical and at the same time to give a better service to their patrons.

Paterson, N. J.—The Paterson and Little Falls Railroad Company and the People's Park Road Company have united under the name of the Paterson and Little Falls Railway Company, with the following officers: F. C. Van Dyk, president; Charles A. Johnson, of Brooklyn, vice-president; James A. Morrisse, treasurer; John J. Scanlan, secretary.

Niagara Falls.—The electric railway line of the Niagara Falls Park and River Railway Company, between Chippewa and Queenston, has been completed. The power house from which this line is operated is the first of its kind run with Niagara power.—The Pittsburg Reduction Company, the only manufacturer of aluminum on a commercial scale in the United States, intends to establish its works at Niagara Falls, and has executed a lease with the Niagara Falls Power Company for 6,500 electrical horse power for the operation of its machinery.

Brooklyn, N. Y.—The State Railroad Commission will give a hearing in the Common Council chamber in Brooklyn on July 25 on the application of the Kings County Electric Railroad Company, the Nassau Electric Railroad Company, the Broadway Railroad Company, the

Coney Island, Fort Hamilton and Brooklyn Railroad Company and the Broadway Ferry and Metropolitan Avenue Railroad Company, all of Brooklyn, for permission to use electricity as a motive power; on the application of the Brooklyn City Railroad Company for permission to use electricity on proposed new routes, and on the application of the Montauk Extension Railroad Company for permission to construct its proposed road.

New York.—The Broadway Railroad Company intended to use its cable conduits to run wires in for a telegraph system, to be used in case of accidents such as occurred recently, but the Empire City Subway Company has obtained a temporary injunction restraining the railway company from using the cable conduits on the ground that the law forbids the use of any conduits but those owned by the subway company. —Several members of the Bridgeport, Conn., boards of aldermen and councilmen have been officially investigating the Waddell-Entz storage battery system now in operation on the Second Avenue Street Railway line in this city, with a view to its use on the Bridgeport lines if the committees were convinced of its superiority over the trolley for city railway service. Their decision is not yet made public.

Philadelphia.—The minority stockholders of the Penn Electric Company have petitioned the Chancellor of New Jersey for the appointment of a receiver to protect their interests. This is the outcome of the recent stockholders' meeting in Camden. The conduits of the company in Philadelphia are used exclusively by the Edison Company, in which the majority of the Penn stockholders are interested. The Edison Company pays only $7,000 annual rental for this exclusive franchise, and the Penn Company barely pays expenses. The minority stockholders claim that if the conduits were open to all competing companies they would receive dividends on their stock.

Chicago. — The Chicago City Council has passed an ordinance granting a franchise to the Jefferson Electric Street Railway Company to construct an electric railway on Lawrence Avenue. The road will connect several of the suburban towns, including Mayfair and Irving Park. The survey is nearly completed and construction work is to begin immediately. It is expected that the road will be in operation before September.—The Great Western Manufacturing Company of Chicago and Duluth gave notice to the stockholders last week that the directors had declared a semi-annual dividend of 4 per cent. The company was recently organized by the combination of several electrical concerns, including the Great Western Electrical Supply Company and the Fare-Bain Electric Company.—The managers of the Lake Street Elevated Railroad, who are about ready to start their trains running through the west division of the city, have decided to equip the Lake street bridge with electrical apparatus and install an electric light and power plant so as to turn the bridge and light the road from the same station.

Lundell Fan Motor Outfit.

The building at the corner of Fifty-fifth street and Seventh avenue is now occupied by Tattersall, and is used as an auction market for horses. Lundell fan motors, depending from the gallery into the ring, are arranged in such a manner that the spectators are unconsciously cooled into a "buying mood."

Taylor, Goodhue & Ames's Catalogue.

The catalogue recently issued by Taylor, Goodhue & Ames, of Chicago, is receiving the well merited attention that it deserves by the public interested in electrical supplies, as is shown by the large demand for it from central station men. The book, although brief in its descriptions, contains a full list of all the supplies necessary around a central station or a contractor's warehouse.

The catalogue contains 212 pages, including an alphabetical and general index of seven pages. The extent of the index affords a ready reference to any article or class of supplies mentioned. The merits of the specialties handled by the firm, such as the Wagner Motors and Dynamos, Century Insulated Wires, Columbia Incandescent Lamps, Burton Electric Heater, etc., are particularly well set forth and will afford interesting and profitable reading to all portions of the electrical fraternity.

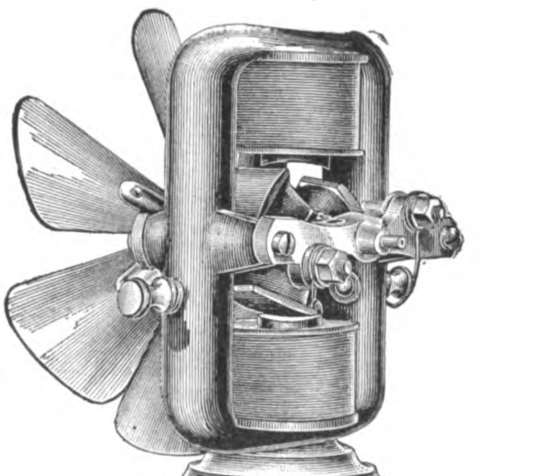
Day's Kerite Insulated Wires and Cables.

The Price List of Day's Kerite Insulated Wires and Cables is a very neat little work and gives a great deal of tabulated information in regard to the Kerite goods and to cognate matters that is calculated to make it serviceable as a guide to every purchaser of such materials and to all who are concerned in telegraph, telephone or signal construction work. The book contains some excellent hints in the prefatory notes, and a number of tables are given showing the different sizes and capacities of wire, with the amount and kind of insulation used, to which the price (f. o. b. at the factory) is affixed in each case. Other tables show the dimensions and resistances of pure copper wires, wire gauges in decimal parts of an inch, weight of copper wire, etc. The illustrations are numerous and exhibit the different kinds of Kerite insulation and the many forms in which it is applied to single wires and to aerial, submarine and underground cables. The Price List can be obtained by application at the office of W. R. Brixley, manufacturer, 203 Broadway, New York.

The Palmer Fan Motor.

The use of fan motors has become so general that these machines are to be classed among the necessities rather than the luxuries, and they are now manufactured at a price which easily puts them within the reach of everyone. The motor shown below is manufactured by Palmer Bros., Mianus, Conn., and is designed to run a 6-inch blade fan or a sewing machine or other small tools requiring from 1-12 to 1-16 H. P. They are wound for 110 volt circuits, or for batteries, thus making them applicable for localities without electric light service.

The fans are readily removed and a grooved pulley substituted when wanted for running machinery. The parts of the motor are also furnished in the rough, or finished and fitted for those who desire themselves to wind them. Directions for doing this are supplied with the parts. The complete motor or the separate parts are sold at a low price, and will be found not only highly conducive to comfort, but instructive to those who undertake the winding and finishing of the parts.



THE PALMER FAN MOTOR.

Catalogue of Railway Apparatus.

The Westinghouse Electric and Manufacturing Company's descriptive catalogue of Railway Apparatus manufactured by the company at Pittsburg is an exceedingly handsome book, with the title on the cover page printed in raised gold bronze letters partly overlapping an attractive engraving showing a Westinghouse trolley car and wiring equipment. The book is splendidly printed in large, clear-cut type on heavy calendered paper, and is embellished with beautiful electrotype illustrations of railway apparatus manufactured by the company, as follows:

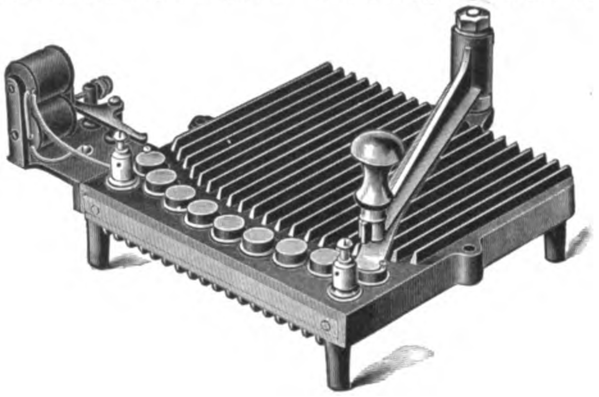
No. 3 Single Reduction Railway Motor.
No. 3 Single Reduction Railway Motor, Open.
No. 3 Single Reduction Railway Motor Castings.
No. 3 Single Reduction Railway Motor Armatures in Construction.
Street Car Diverter.
Series Multiple Controlling Stand, with and without Cover.
100 H. P. Multipolar Belt Driven Railway Generator.
Winding of Multipolar Railway Generator Armature.
Multipolar Railway Generator Armature, Complete.
700 H. P. Multipolar Belt Driven Railway Generator.
Multipolar Railway Generator Direct Connected to Westinghouse Engine.

The descriptions accompanying the illustrations have evidently been prepared by a writer thoroughly conversant with all the details of the apparatus he treats of, and are conveyed in a clear and incisive style that leaves nothing misunderstood. The book should be on the desk of every man interested in electrical railways and their effective and economical equipment.

Climax Ironclad Rheostats.

These rheostats are made on the principle that the carrying capacity of a wire not only depends upon its diameter but also on its ability to dissipate the heat generated by the passage of the current through it. It is obvious that if a wire be encased in an electrical non-conductor which doubles the diameter of the original wire its resistance per foot would not be decreased, but the surface exposed to the air for radiating purposes would be twice as great as that of the wire itself.

In the Climax ironclad rheostats the wire is wholly imbedded in a solid plate of insulating material which is completely encased by and in intimate contact with an iron covering. The heat is readily conducted from the resistance wires (as they are only one-sixteenth of an inch from the iron), and rapidly dissipated by the iron shell, which has a radiating surface many times greater than the wire. The entire shell, top, bottom and sides, being of metal insures the greatest possible radiating surface for the cubic space taken up, and gives a device that will stand rough usage and wear unharmed.



CLIMAX IRONCLAD RHEOSTAT.

The contact points, binding posts and lever are firmly attached to the iron covering and insulated by mica, connections between them and the resistance wires being made within the plate of insulating material while it is in a plastic condition, so that no portion of the wires or connections is exposed to the air. This feature enables the wires to be subjected to high heat if necessary, without danger of oxidation, and as they are completely imbedded in a solid mass, they are not liable to mechanical injury.

Motor speed regulating rheostats, as well as starting boxes for motors made in this type, are very compact; the latter are made with or without an automatic release. This release, illustrated in the accompanying cut, takes very little power, the magnets merely operating a latch, instead of holding the lever directly against the pull of a spring as in ordinary practice. This difference in construction will tell in the efficiency of the motor in the small sizes.

Dimmers for theatre use are also made in this type. The resistance, switch and contact points are all made in one case which is placed in the wings, exactly the same as the old style switch and taking up no more space. One of the principal advantages of the device is the simplicity of installation—the two mains only having to be run to the two binding posts—as contrasted with the old method of placing the switch in the wings and the resistance off in some distant place, running wires from it to each separate contact on the switch, at a cost for installation greater in many cases than the original cost of the rheostat.

These goods, as well as all kinds of special resistance devices, are sold by McDougall & Cummings, Unity Building, Chicago, and the Knapp Electrical Works, Chicago.

The Queen Conductivity Bridge.

Probably one of the most difficult and at the same time important measurements to make is that of conductivity. As usually conducted long lengths of wire or cable are required and extraordinary precautions taken as to temperature, while a number of expensive instruments, perhaps not adjusted to each other, form the testing outfit. Under these conditions accurate results are only obtainable at the hands of skillful operators.

The accompanying figures show in perspective and in diagram a "Conductivity Bridge" designed by Queen & Company, of Philadelphia, by means of which the measurement of minute resistances is greatly simplified and freed from many of the errors to which it is commonly subject

Referring to Fig. 2, R1 and R2 are two approximately equal resistances (not necessarily known); S1 and S2 represent two *groups* of resistances, each group consisting of a fundamental resistance connecting together two copper bars, as b and b′, and six accessory resistances arranged so that any one can be placed in parallel with the fundamental. One end of each accessory resistance is joined to a mercury cup between the two outside bars; a small copper connector, C, joins the mercury cap to the lower bar as shown in the diagram. These fundamental resistances are initially adjusted very accurately, so that the two groups will differ in resistance by the decimal engraved below whatever cup the connector, C, is bridged into. A, A, A, A are heavy copper connectors making connections between the various copper bars as shown. These connectors are carried by a heavy rubber plate as shown in Fig. 1.

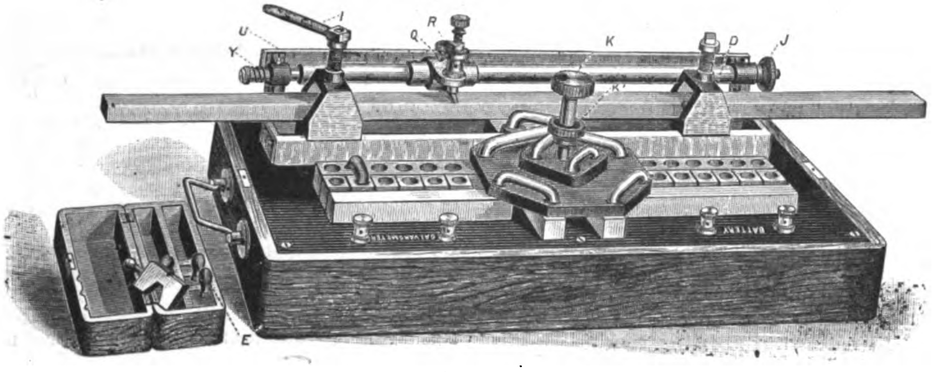


FIG. 1.

In the front of the apparatus is a massive pair of ways, G, upon which slide heavy clamps, D; each of these ways is joined to one of the groups S1 and S2. The connector to be tested, H (Fig. 2), seen as a square bar in Fig. 1, is slipped into the heavy clamps, D, and clamped down by means of the screw nut H and wrench I. A scale, U, 50 cms. long and divided to millimetres, is supported in front of the test piece as shown in Fig. 1. Upon a rod behind this scale moves a slider by which galvanometer contact is made upon the test piece. A fine adjustment of the slider may be obtained by means of the micrometer screw, T. The bernier, V, allows setting to be made to 1-20 mm.

This method of operation is very simple. The test piece being in position, connector C is placed in such a cup as will make S1 and S2 differ by *about* the resistance of the test piece. A few trials will determine this, or the resistance of the test piece as given by any wire table will be close enough. Battery and galvanometer circuits being connected as shown, the slider is moved along until no deflection of the galvanometer is produced, when the circuits are closed. The heavy connectors A, A, A, A are now rotated through 180 degrees: this is accomplished by merely lifting the head, K, of the plate which supports them and turning it through the above angle. The smallest plate carrying connectors L, L will thus be rotated so as to leave L, L in the same relative position. The effect of rotating A, A, A, A will be, as is evident on tracing out the connectors, to exchange S1 and S2, and this obviously will push the position of the slider contact corresponding to zero galvanometer deflection along the test piece until the amount of test piece moved over equals in resistance the difference between S1 and S2. All that must be done, therefore, is to take two balance readings; the length of test piece moves over equals in resistance whatever difference may be originally established between S1 and S2.

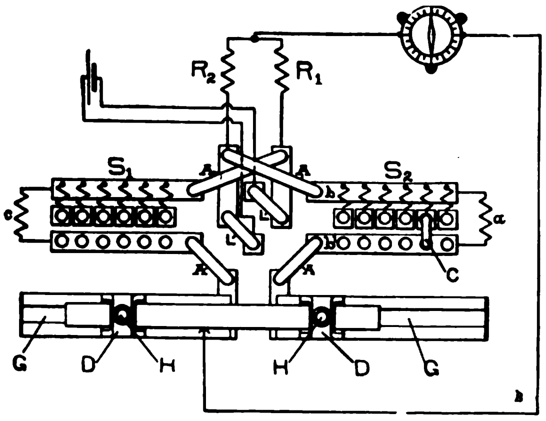

FIG. 2.

All contact errors, where the test piece is clamped in, are eliminated in this apparatus, e. g., any contact resistance in the left hand clamp merely operates to throw *both* balance readings to the right, leaving their difference unchanged.

The entire apparatus being constructed of copper, thermal currents will not usually be of any appreciable moment. They may be eliminated, however, by reversing the battery and taking the mean of two readings as the true slider readings. That is easily accomplished by lifting head K and rotating connectors L, L through 90 degs.

To accommodate conductors of different sizes and shapes, a number of little adjusting blocks, E, are provided; these blocks fit into the clamps, D, and hold the axis of the test piece whether round, square or otherwise shaped in cross section exactly in the axis of the clamp. With this apparatus the conductivity of copper bars up to ¾ inch in diameter, less than 12 inches long, may be measured with an accuracy of 1-50 of one per cent. The resistances R1 and R2, S1 and S2 are standards, permanently a part of the apparatus and guaranteed accurate to 1-100 of one per cent.

This method and apparatus are the result of long continued study and experiment in the laboratory of Queen & Company. The set is handsomely and substantially made, and occupies a rectangular case 22⅝ by 11⅛ by 8⅝ inches deep. Wire manufacturers will see in this apparatus a means of saving much time and expense as well as of raising the standard of their goods. Manufacturers of dynamos, motors, also will find the set extremely valuable in determining whether their armature conductors are up to the proper standard of conductivity. A sample set now in the Queen exhibit at the World's Fair attracts great attention, and has been purchased for installation in the testing department of the Armour Institute, Chicago.

Slate for Electrical Uses.

Mr. Edward Bonville, of Fair Haven, Vt., whose advertisement may be found elsewhere in this paper, carries on a very extensive business in the manufacture of slates for various electrical purposes. He finishes his slates to meet the requirements of all fancies in form, color and finish, such as round turned slates, slates with square edges, rounded edges, bevelled edges, slate bases for jackknife switches, finished in several colors to suit—imitation Tennessee marble, imitation onyx, etc., etc. There is a large demand among electrical men for his switchboards, which he finishes in any desired marbleized colors, or in deep black with highly polished surfaces, and we have reason to believe that Mr. Bonville's materials and workmanship fully deserve the increasing custom that he is enjoying.

COMMERCIAL PARAGRAPHS.

The Ansonia Electric Company were recently awarded the contract for the entire equipment of Stanley Transformers, Helios Arc Lamps for street lighting, Shield Brand Moisture Proof Wire for line wire, and other line supplies by the Hillsdale Common Council. This plant will have a capacity of about 2,000 lights in converters and about 50 arc lamps. The Hillsdale Council decided on using Helios lamps and Stanley transformers after most carefully investigating practically all other systems on the market and the contract was awarded by a unanimous vote.

The Ansonia Electric Company are making large sales in the Wirt Dynamo Brush, one good sized order coming from the National Metal and Electrical Company, Cleveland, Ohio.

The Maquoketa electric light plant, recently equipped with Helios Arc Lamps furnished by the Ansonia Electric Company, is to begin operating its street circuits this week.

The Imperial Music Hall is completely equipped with Lundell Fan Motors. This is another instance of an installation in a place of amusement after a thorough trial of many fan motors, the choice being for the Lundell. The Hotel de Logerot, the New Amsterdam, and many private residences have them.

The Eddy Electric Manufacturing Company of Windsor, Conn., have recently sold to the Whitman & Barnes Manufacturing Company, of Chicago, one 65 K. W. direct connected generator, one of 200 K. W., same type, and motors of various sizes aggregating 389 H. P. The sale was made by Mr. B. M. Barr, of the company's Cleveland office.

The Electrical Engineering Company, E. G. Bruckman Manager, of St. Louis, has been awarded the contract for the installation of the electric light work on the new Union Depot in that city, being one of the largest of its kind in the world, 600 by 700 feet. They have also been awarded the contract for 6,000 incandescent lights on the Union Trust Company's fourteen-story building, now in course of construction.

The Electrical Engineering and Supply Company, which has recently removed from St. Paul to Minneapolis, has already secured a number of nice orders, among them the electrical equipment of the department store of S. E. Olson & Company. This plant will be the largest isolated plant in the Northwest, consisting of Standard arc light machines of 180 lamps capacity and an incandescent plant of 800 light capacity. The contract includes wiring and installing the machines complete. They have also closed a contract for wiring a store and office building for 430 lights, in which Paranite Rubber Covered Wire will be used. Orders are coming in more freely than in June, the business depression having apparently run its course.

A neat pamphlet containing a detailed presentation of the construction, uses and merits of the Kolon Primary Battery has been published by Bryan, Marsh & Company, Electrical Exchange, 1[illegible]6 Liberty street, New York. Numerous cuts are given in the book of the several types of the Kolon Battery manufactured by the company and of electrical apparatus and appliances which they have on sale, among which are Kolon Battery lamps, lamp outfits and accessories, sewing machine outfits, medical outfits, dental outfits, etc. Prices of the articles are given in each instance. A number of testimonials are appended in which the Kolon Battery and Cells are highly extolled.

INCORPORATIONS.

The Excelsior Electric Light Company of Tarrytown—to manufacture and use electricity for light, heat and power. Capital stock, $50,000. Directors: S. Dana Green and George W. Davenport, of New York City, and Frank P. Slade, of Brooklyn.

The York and Wrightsville Electric Railway Company, York, Pa.—to construct and operate an electric railway in York County, Pa. Capital stock, $75,000. Promoters: Grier Hersh, L. A. Marshall, Chas. H. Mayer, York, Pa.

The York and Manchester Electric Railway Company, York, Pa.—to construct and operate an electric railway in York County, Pa. Capital stock, $50,000. Promoters: Chas. H. Meyer, Geo. P. Smyser, Geo. S. Billmyer, York, Pa.

The York and Dover Electric Railway Company, York, Pa.—to construct and operate an electric railway in York County, Pa. Capital stock, $50,000. Promoters: Grier Hersh, L. A. Marshall, Chas. Mayer, York, Pa.

The Electric Burglar Alarm Company, Chicago. Capital stock, $250,000. Incorporators: Jacob Lindheimer, George D. Hoffman, Jacob S. Hoffman.

Charters have been granted at Harrisburg, Pa., to Crystal Lake Street Railway Company, of Carbondale, capital $50,000, and the Alleghany and Kiskiminitas Electric Railway Company, capital $100,000.

The Milwaukee Electric Street Railway Company, Milwaukee, Wis.—to operate a street railway in the city of Milwaukee. Capital stock, $800,000. Promoters: Chas. F. Pfister, Chas. Landree and Chas. Quarles.

The Enosburg Falls Electric Light and Power Company, Enosburg, Vt.—to furnish electric light, heat and power to the inhabitants of Enosburg and vicinity. Capital stock, $10,000. Promoters: Henry F. Holland, Clarence F. Eldridge, Boston, Mass.; H. D. Kendall, Ira H. Kendall, John Fish, Enosburg, Vt.

The Elwell Parker Electric Company of America (incorporated in West Virginia), Cleveland, Ohio—to manufacture, buy, sell, etc., electric dynamos, motors, machines and all material, apparatus, etc., appertaining thereto. Capital stock, $500,000. Promoters: Elbert H. Phillips, Frederick C. Phillips, Alex. E. Brown, all of Cleveland.

The Macomb Electric Company, Macomb, Ill.—to supply light, heat and power from electricity. Capital stock, $30,000. Promoters: J. H. Cummings, H. W. Cummings and Chas. Kettron.

The Chicago and Central Indiana Electric Railway Company, Chicago—to organize, build, equip and operate, buy and sell street and dummy railroads for carrying freight and passengers. Capital stock, $5,700,000. Promoters: George A. W. Kintz, Nevin D. Pontius and George S. Foster.

The Hightstown Electric Light and Power Company, Hightstown, N. J.—to erect, maintain and operate an electric plant to supply light and power in the borough of Hightstown. Capital stock, $50,000. Promoters: J. Shields, Flemington, N. J.; N. W. Bindsell, R. H. McCarter, Newark, N. J.

The Military Electric Land Company, of Buffalo, N. Y. Capital stock, $85,000. Directors: Wilson Sherk, Phillip J. Kieffer, George E. Cross and others of Buffalo.

The Chestertown Telephone Company—to operate telephone lines between the towns and villages in Warren, Essex and Hamilton Counties, N. Y. Capital stock, $3,000. Directors: Fred. K. Vetter, Stanley H. Bevins, Charles H. Burge, Max S. Bevins, Jennie Vetter, Florence Burge and Winifred M. Bevins.

WESTON ELECTRICAL INSTRUMENT COMPANY'S WORLD'S FAIR EXHIBIT. (SEE PAGE 14.)

World's Fair News.

The Weston Electrical Instrument Company's Exhibit.

The display of electrical measuring instruments made by the Weston Electrical Instrument Company in the Electricity Building at the World's Fair is shown in our Frontispiece, and is one of the most interesting exhibits to be found in the building. It is located on the gallery floor near the southeast corner, and is very handsomely constructed and decorated.

The instruments are placed in a number of show-cases, arranged in the form of a square, the whole being surmounted by large signs bearing the company's name. To the rear of the show-case the company have fitted up an elegantly furnished office in which friends and visitors are entertained by Messrs. R. O. Heinrich and Fred. O. Runyon.

Over two hundred and fifty instruments of various kinds are shown in the exhibit. Among these may be mentioned the ordinary station voltmeters and ammeters, portable standard voltmeters and ammeters, millivoltmeters and milliammeters. Several types of the same instrument, but standardized for different readings, are shown. Numerous special instruments are on exhibition, among which may be mentioned the portable standard wattmeter, isolated plant voltmeter, static voltmeter, lamp-testing instrument, tangent galvanometer, vertical scale instrument and a ground detector. Nearly all of the instruments exhibited are connected to a circuit, so as to show them in actual operation. Visiting central station men or persons interested in electric lighting in any way will find that an hour spent under the guidance of either Mr. Heinrich or Mr. Runyon in the Weston Company's booth will not only be interesting but valuable. The gentlemen in charge have placed a register in the booth for all visitors desiring catalogues sent to their address.

The committee appointed last week to judge the electrical exhibits in the Electricity Building and Machinery Hall met in their temporary quarters, which is near Chief Barrett's headquarters, and elected Professor H. S. Carhart, of the University of Michigan, as president of the committee. Professor William E. Anderson, of the Virginia Agricultural and Mechanical College, was elected secretary. Very little business other than the routine of organizing the committee was transacted. It is expected that the committee will have the rules and regulations governing its decisions drawn up before the end of the week. It will then proceed to pass upon the merits of each exhibit.

The personal exhibit of Professor Elihu Thomson has recently been completed, and is attracting its share of the crowd which is always found in the Electricity Building. The exhibit is located in a space a little to the east of the central tower of light. The exhibit consists principally of experimental apparatus used in showing the various effects of extremely high voltage currents. A portion of the space is devoted to historical apparatus taken from the Lynn factory, most of which was designed and used by Professor Thomson in his early experiments.

The temporary track which has been laid near the terminal station is nearly completed and ready for the reception of different street cars and motors which are to be exhibited on it. The track is substantially built, of the latest designed rails and ties. It is expected that all the street-car manufacturing companies will have cars on the track for the judges to test. The General Electric Company has signified its intention of placing one of its new electric locomotives on the track.

The Standard Electric Company have a very interesting piece of apparatus in the centre of their exhibit in the Electricity Building. It consists of an arc lamp placed so that the arc is in the focus of a large lens which projects an image of the arc on a canvas stretched across the end of a small room. By this arrangement the movements of the arc can be readily followed.

Practical Aspects of Low Frequency Electrical Resonance.—II.*

BY M. I. PUPIN, PH.D.

5. RESONANCE IN CIRCUITS WITH AN IMPRESSED COMPLEX HARMONIC ELECTROMOTIVE FORCE.

If the impressed E. M. F. is a complex harmonic, then the circuit may be brought into resonance with any of the component harmonics. I have an apparatus here which is capable of producing E. M. F. of almost any complexity. I call it an *electro-dynamic current interrupter*, for want of a better name. It consists of a phosphor-bronze wire, the vibrator, a, b, e (Fig. 6), stretched between the poles of a Weston horseshoe magnet d. A short, thin, amalgamated copper wire b, the dipper, is soldered on the vibrator. The vibrator is stretched like the wire of a monochord, over two hard rubber bridges a e, and its tension can be varied by a screw and lever f. The dipper c whenever it dips into the mercury cup closes an electrical circuit $F f e b c g A$, and the vibrator is then repelled upward by the force of repulsion between the magnet and the current flowing through the vibrator. One gravity cell f is sufficient to work this apparatus. It is evident that the fundamental period of the interrupted current will be equal to the period of the vibrator. To change this period, say to make it equal to the period of this tuning fork, which is 256 complete vibrations per second, I simply strike the tuning fork, hold it then near my ear and by turning the screw f of the stretching lever I vary the tension of the vibrator until the rate of the vibrator and that of the tuning fork are in perfect unison, which can be easily recognized by watching the beats. This whole process of tuning takes up, as you see, only a few seconds. In series with the cell F and the vibrator we have a small coil A, containing a well packed bundle of very thin iron wire, and in shunt with A is a condenser D. This condenser performs the function of bringing this primary circuit into partial resonance with the vibrator, which is recognized by the circumstance that at the moment of resonance the spark at the dipper is a minimum.

A simple reflection will show you that the current generated by this interrupter is a complex harmonic. To analyze it into its component harmonics I shall adopt the methods employed in acoustics.

A complex sound is analyzed by the well-known resonators of Helmholtz. These resonators are constructed in such a way that they will respond to one vibration only, and also in a measure to its upper harmonics. To any other vibration they are practically mute. By a number of such resonators we can find out, in the manner first pointed out by Helmholtz, all the vibrations which are contained in a complex sound.

The secondary circuit B C T E, given in the diagram of Fig. 6, performs the function of such a resonator—it is in fact *an adjustable electrical resonator;* C is a small auxiliary coil which you see here; E is a Marshall condenser, and T is a telephone whose note tells me to which of the component harmonics the electrical resonator responds. The telephone is silent now, at any rate as far as you can tell, because the condenser plugs are all out. Now, with this plug I insert a small capacity. The note which you hear is evidently much higher than even the octave of the vibrator. The electrical flow in the resonating circuit is approximately the same as if we had in it a simple harmonic E. M. F. of the same frequency as this note. I insert another plug, so as to increase the capacity. The note which you now hear is deeper. The difference between the two notes is rendered very striking by making and breaking the contact of the second plug in rapid successions, as I do now. The sound of the two notes, succeeding each other at regular intervals, resembles very much the sound of bagpipes. I insert another plug, so as to increase the capacity still more. The note which you now hear is still deeper. It is the note of the fundamental electrical vibration, which is the same as the vibration of the vibrator. I know that, because as I continue inserting more and more plugs you do not perceive any further change in the sound. The capacities which I introduced by the three plugs are to each other very nearly in the ratio of 1 : 9 : 25, hence the frequencies of the three harmonics contained in the impressed E. M. F., and which I have detected by the resonating secondary circuit, are to each other in the ratio of 1 : 3 : 5.

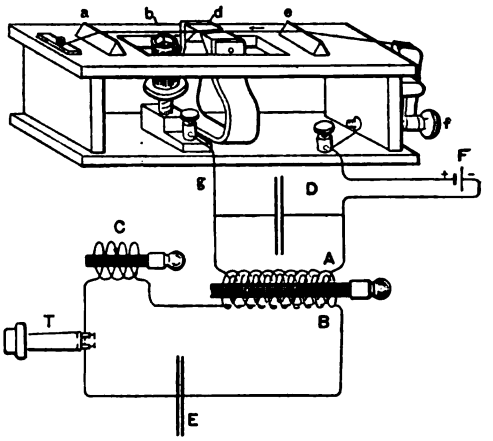

FIG. 6.

The impressed E. M. F. can therefore be written

$$E = E_1 \sin pt + E_3 \sin 3\,pt + E_5 \sin 5\,pt.$$

Still higher harmonics are present, but they are too weak to be heard all over this room.

I shall presently discuss a method by means of which we not only detect the presence of these harmonics, as I have just done by means of this telephone, but also determine the relative strength of each. The method imitates in a certain measure Prof. Langley's bolometric method of determining the distribution of energy in the spectrum of a given complex luminous vibration.

Before making the next step in my discourse I wish to call your attention to an application of resonant circuits (in connection with the electro-dynamic interrupter) to a method of producing simple harmonic currents of constant and easily determinable frequency.* I simply tune the vibrator by means of a standard tuning fork, and then weed out the upper harmonics by successive transformations. In this connection I ought to mention that Professor Duncan of Johns Hopkins University informed me several weeks ago that he was also weeding out harmonics. I now remember that I got the expression "weeding out" from him, but I have used it in my papers on "Low Frequency Resonance" without giving him credit for this beautifully selected expression.

6. ON THE RESONANT RISE OF POTENTIAL.

The question arises now, how are we to tell experimentally whether a circuit is in resonance to an impressed E. M. F. or not? Several methods suggested themselves to my mind in the course of my work. I selected the one which appeared to me to be the most sensitive and most interesting. *It also suggests a new way of transforming electrical energy which some day may perhaps be of some practical importance.* I wish to discuss this method now, but only very briefly.

---

* A lecture delivered at the Tenth General Meeting of the American Institute of Electrical Engineers, Columbia College, New York.

* Pupin, "Electrical Oscillations of Low Frequency and their Resonance."—*American Journal of Science*, April, 1893.

As I observed before in the discussion of the motion of the torsional pendulum, represented in Fig. 5, when the moving force and the pendulum are in resonance then both the amplitude of oscillation and the amplitude of the velocity reach their maximum value. And so it is also with a circuit possessing self-induction and capacity. By varying gradually the one or the other, the current (which corresponds to the velocity of the pendulum) will continually increase. But the difference of potential in the condenser (which corresponds to the elastic reaction of the suspension wire) will also increase continually. When the point of resonance has been reached then evidently both the current and the difference of potential in the condenser have reached their maximum values. This maximum difference of potential in the condenser can be many times greater than the impressed E. M. F., because just as in the case of the torsional pendulum the elastic reaction of the suspension wire is an accumulative effect of the moving force, so in the electrical circuit the potential difference in the condenser is an accumulative effect of the impressed E. M. F. Now, since a resonant electrical flow, which we have just considered, consists simply of a transformation of electrokinetic into into electrostatic energy, and *vice versa*, during each half period, accompanied by a frictional loss due to ohmic resistance, it is evident that the amplitudes of these two kinds of energies must be equal to each other, that is, we shall have in the usual notation

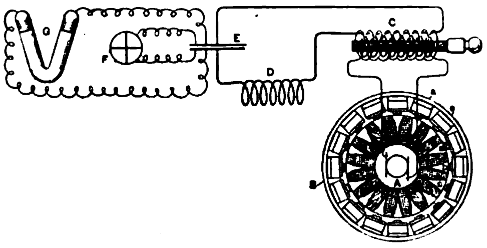

FIG. 7.

$$\tfrac{1}{2} P^2 C = \tfrac{1}{2} L \frac{E^2}{R^2}.$$

But since owing to resonance we have $p^2 L C = 1$, the preceding relation reduces to

$$P^2 = p^2 L^2 \frac{E^2}{R^2} \text{ or } P = p L \frac{E}{R}.^*$$

It is evident, therefore, that with a little more than ordinary frequency, say 350 periods per second, and an inertia coil of considerable self-induction and small resistance, high potentials can be obtained in the condenser by bringing the circuit in resonance with the impressed E. M. F. *Connecting, therefore, the condenser to a voltmeter we can tell very accurately when in the course of our tuning of the circuit we have reached the point of resonance, because, as I shall presently show you, the voltage goes up very rapidly when the condenser capacity or the self-induction are near the point of resonance. It is this electrometric method which I have employed in my investigations on ' Low Frequency Resonance."* †

The same method can be and has been employed by several investigators in the study of Herzian oscillations.

To show you how strong this resonant rise of potential can be I have within the last few days wound these two inertia coils (see coil *a′ b′* in Fig. 8) and borrowed this most excellent mica condenser from our well-known electrician, Mr. Wm. Marshall, for which kindness I feel very grateful to him. The impressed E. M. F. is obtained in the following way: A small 16-pole alternator running at about 2,800 revolutions per minute and generating an E. M. F. of about 600 volts feeds the primary of this small transformer (*c d*, Fig. 8). Diagram Fig. 7 gives the form of armature A and field B of the machine. Coils *a b c d e* show how the machine is wound. The transformer consists of a hard rubber spool wound with about 3,000 turns (Fig. 8) of No. 20 A. W. G. wire for the primary. The secondary *h k* consists of about 500 turns of No. 16 wire. A well packed bundle *e* of very fine iron wire is the iron core. This transformer is indicated by C in Fig. 7. In series with the secondary we have inertia coils D and the above mentioned mica condenser E of 0.2 M. F. capacity. The inertia coils consist of hard rubber spools like *a′ b′*, Fig. 8, wound with No. 14 wire. The total self-induction of the secondary circuit is about one henry, *without iron in the inertia coils*. The poles of the condenser E are connected to a Sir William Thomson electrostatic voltmeter F and also to a vacuum tube G with condenser electrodes, that is to say, tinfoil coatings on the outside of the tube. (Indicated by the shaded parts in the diagram.) I now start the machine and by weakening the field of the driving motor I gradually increase the speed of the machine. As you see, the voltmeter needle is steadily advancing with the speed. To get the greatest deflection of the needle I ought to have about 350 periods per second. Now I shall advance to very near this speed. The voltmeter indicates now 2,000 volts. The impressed E. M. F. in this secondary resonating circuit is only about 100 volts. Instead of increasing the speed so as to reach the point of perfect resonance I prefer to leave the speed constant, and by gradually inserting these five iron wires to increase the coefficient of self-induction until that value is reached which with the given speed and capacity brings the circuit in resonance with the impressed E. M. F. I am doing this now and watching the voltmeter needle at the same time. Now the voltmeter indicates 3,000 volts, which is 30 times the value of the original E. M. F. This is the point of resonance, because if I push the iron wire lower the needle goes back. The point of resonance is very sharply defined, because the slightest motion of the iron wire one way or the other makes quite considerable difference in the reading of the voltmeter. The point of resonance can be shown to a large audience like this much more easily by connecting the poles of the condenser to the tinfoil electrodes of the vacuum tube G. A discharge starts in this tube at about 2,000 volts. Now, as I insert these iron wires into the inertia coil you see the intensity of the discharge increases. [The room was darkened.] The point of maximum resonance is clearly marked by the intensity of the discharge, as you see. Now I insert the iron wire too far; as you see, the discharge is stopped. I can start it again by raising the iron and stop it again by taking the iron wire entirely out, as you see.

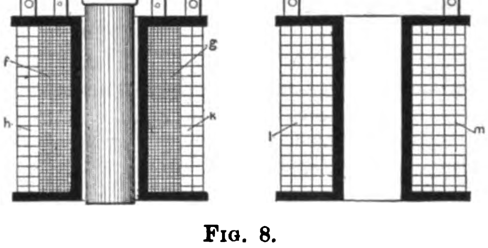

FIG. 8.

By working with high frequencies and small ohmic resistance any voltage within practical limits can be obtained. Ohmic resistance, however, is not the only thing which limits the resonant rise of potential. *Dielectric hysteresis* and the *peculiar behavior of iron under the inductive action of a rapidly alternating current* modify that rise very much. The other day I employed this home-made condenser in parallel with that Marshall mica condenser. I obtained only 2,000 volts rise, whereas preliminary calculation led me to expect at least 4,000 volts. *But the smell of melting wax reminded me forcibly of the cause of this discrepancy. The home-made condenser got so hot in about two minutes that all the wax* (which when boiling hot was compressed between its mica plates to drive out the air and moisture) *between its plates was melted.* The energy which was thus used up in overcoming the dielectric hysteresis of the wax had prevented the resonant rise from reaching that value which it ought to have reached according to calculation. Taking this condenser out and using the mica condenser alone the rise went right up to a point considerably above 3,000 volts. Paraffin and glass behave in a similar way. *So that owing to dielectric hysteresis alone the resonant current* (which takes place when capacity and self-induction neutralize each other) *is never equal to the electromotive force divided by the ohmic resistance, and it can be very much less. The presence of iron is incomparably more powerful in destroying the resonant rise of current and potential, as will be seen presently. This is very unfortunate in view of the brilliant expectations which not a few electricians hoped to realize from the employment of condensers in the running of alternating current machinery.*

It is well to observe here that if we substitute a Weston voltmeter for the Thomson electrostatic voltmeter F, Fig. 7, then we shall have practically the condenser in parallel with the inertia coils. It is easy to see from purely theoretical considerations that the resonant rise will be less in this case. Experiments show that the rise can be then very much less if the resistance of the voltmeter circuit is reduced. *The bearing of this observation on the so-called Ferranti effect with and without a load in the mains needs, I venture to suggest, no further discussion.*

(*To be continued.*)

Compressed Air and Electricity.

The economy of electricity over compressed air for long distance transmission of power has been pretty thoroughly established, but Mr. Cox, director of the electro-technical department of the Esslinger-Cannstatt Works, has given some figures which still further point to the conclusion. In a paper before the Association of Engineers of Würtenburg, Mr. Cox gives some interesting figures in regard to the cost of equipment and operation of a plant of 217 H. P. for transmission of power to a distance of 5.500 km. both by compressed air and by electricity.

The cost of the equipment of the former method includes the dam for the water fall, the turbines, the compressors, the piping and the air motors, and for the electric plant and generators, underground wiring and the motors. The cost for compressed air amounts to $87,500 and for electricity $27,500, while with the former the guaranteed efficiency is 46 per cent., and in the latter case 69 per cent. including a loss of 15 per cent. in the wiring. The cost of operation is practically the same for both systems, but only 100 H. P. is actually available with the compressed air while 150 is delivered by the electric system. This makes the cost per horse power delivered in the one case $37.50 and in the other case $18.85, and as the charges for depreciation are somewhat less for electricity than compressed air this still further favors its economy.

Judge Seaman's Decision.

He Grants the Injunction Against the Oconto Company.

In the U. S. Circuit Court at Milwaukee, on Thursday, July 20, Judge Seaman handed down his decision for the plaintiffs in the case of the Edison Electric Light Company et al. vs. The Electric Manufacturing Company et al. Following is the full text of the decision :

This is a motion for a preliminary injunction. The complaint alleges infringement by defendants, manufacturers of electric lamps at Oconto, Wis., of the second claim of Letters Patent No. 222,398, issued to Thomas A. Edison, January 27th, 1880, and adjudged valid after protracted contests in the Circuit Court for the Southern District of New York, affirmed by the Circuit Court of the Second Circuit. The defendants have answered, the original answer admitting infringement of said second claim as construed in said decisions, but by an amended answer (allowed at the hearing) take issue upon such infringement, avowedly upon their proposed new showing as to the prior state of the art through the alleged Goebel invention, and the narrower construction which should thereby be placed upon said second claim ; and further setting up prior invention by one Henry Goebel, not litigated in the New York case. For and against the motion, voluminous records, affidavits and depositions, with sundry exhibits, are presented, to which reference will be made.

It is shown that litigation in behalf of this patent has been actively carried on since May, 1885, both directly and collaterally ; that after obtaining favorable decisions in other cases wherein issues under this patent were involved, and defending successfully against the Sawyer & Man patent (40 Fed. Rep., 21), judgment was obtained in July, 1891, in its action in the Southern District of New York against the United States Electric Lighting Company sustaining the second claim of this patent, and decreeing injunction (47 Fed. Rep., 454), which was affirmed by the Circuit Court of Appeals for the Second Circuit in October, 1892 (52 Fed. Rep., 300). The defendants in that case having turned over to the Sawyer & Man Electric Company the business of manufacturing, suit was brought against the latter. and injunction granted, and affirmed by the same Circuit Court of Appeals in December, 1892 (53 Fed. Rep., 592).

It further appears that injunctions have been granted against other infringers in this circuit and in other circuits without serious contest, and that in the District of Massachusetts, in complainants' suit against the Beacon Vacuum Pump and Electrical Company, the motion for preliminary injunction was vigorously contested, upon the grounds presented here, and in an exhaustive opinion handed down by Judge Colt, January 18, 1893, the injunction was ordered (54 Fed. Rep., 678). On the other hand, in a suit by complainants against the Columbia Incandescent Lamp Company, in the Eastern District of Missouri, upon similar motion and additional affidavits, an opinion was rendered April 21st, 1893, by Judge Hallett, refusing the injunction if the defendants should give a bond.

All of the records and affidavits before the courts respectively in the Beacon case and in the Columbia case are here, and much additional testimony—that upon the part of the defendants, taken since such hearing, in rebuttal, under an order of this court, being in the form of depositions and with cross-examination of witnesses.

Therefore this court has the benefit of the opinions handed down at those hearings, and the embarrassment as well of deciding here between apparent differences in views as to the measure of proof demanded.

In the opinion in the Beacon case, the rule applicable to this defense against the motion is stated, citing a number of authorities, as follows: "The burden is on the defendant to establish this, and every reasonable doubt must be resolved against him;" also, that "the presumption of novelty is not to be overcome except upon clear and convincing proof." The showing there made is reviewed at length and found insufficient to meet the requirements of the rule.

The opinion in the Columbia case is not yet reported, but in a copy furnished for this hearing the views which control the decision are stated as follows : "There is not the measure of proof demanded by complainants' counsel, who maintain that the court should require proof of the fact beyond reasonable doubt. This degree of certainty is not often attained upon testimony in the form of affidavit when the issue is contested, and it is not reasonable to demand such certainty as to the defense. Complainants must show a clear right in support of a preliminary writ, and a defense which puts the case in doubt is sufficient to defeat the application," and for its conclusion against the injunction, hold : "It is enough to say that there is a fair preponderance of testimony in support of the Goebel claim."

Decisions of the Supreme Court have settled beyond controversy that for the defense of anticipation and prior use against a patent the proofs must be "clear, satisfactory and beyond a reasonable doubt." The Barbed Wire Patent, 143 U.S., 276, 284; Cantrell vs. Wallick, 117 U. S., 689; Coffin vs. Ogden, 18 Wall., 120. And that has been the constant rule in this circuit. Smith vs. Davis, 34 Fed. Rep., 783; Washburn & Moen Mfg. Co. vs. Haish, 4 Fed. Rep., 900, 10 Biss., 65; American Bell Telephone Co. vs. Cushman Telephone Co., 35 Fed. Rep., 739.

The decisions and text books agree upon the general rule stated in the opinion of Judge Colt (p. 679) that an adjudication of the validity of his patent after bona fide contest entitles the complainant to a preliminary injunction and especially after long and expensive litigation in a suit against other infringers, and that the only question open upon his motion therefore is that of actual infringement by the defendant of the claim so adjudged valid. Other defenses are then reserved to final hearing, and injunction issues as of course in the same court and by comity in other courts. One exception to this rule is sometimes allowed, and that is where there is clear showing of a meritorous defense which was not before the court in the original suit, and which, had it entered into consideration, would probably have defeated the patent or claim. It is under this exception that the defendants assert their right to oppose this motion, and their affidavits are directed to proving an invention and use by Henry Goebel prior to that of Edison. Although sundry other claims of priority have been set aside by the court in the course of the litigation, this one was not presented, and the defendants have a right to their day in court for its hearing. The question here is whether there is such clear showing of merit for this claim now asserted that the defendants should be relieved from the general rule by denying in their case the usual injunctional order; and the primary inquiry is, what must be the measure of proof demanded. Must it be of the quality and quantity required to defeat the patent at final hearing—"clear, convincing and beyond reasonable doubt"—as held by Judge Colt; or will it suffice, for denial of the motion, that it show "a defense which puts the case in doubt," as held by Judge Hallett. It is clear that the presumption must be in favor of the patent, and that it cannot be overthrown by a mere doubt. I think the true test for proof upon the motion is that it shall be sufficient to raise a presumption that it would have defeated the patent had it been produced at the trial. This would demand at least the full measure required to overcome the presumptive force of the patent, and that every reasonable doubt be dissolved against the defense, here as it would be there as held by Judge Colt. In the eyes of the law, at this stage, the complainants stand upon their rights with their letters patent, confirmed after arduous contest, and entitled to preliminary injunctions against infringers; and the defendants must place themselves entirely within the exception to the rule if they invoke the privileges of that exception and would deprive the complainants of the fruits of their hard-earned victories. The rule held by Judge Colt will therefore be adopted here, and the following additional authorities are cited as supporting it : McBeth vs. Braddock Glass Co., 54 Fed. Rep., 173; Accumulator Co. vs. Consolidated Co., 58 Fed. Rep., 795; American Bell Tel. Co. vs. Southern Tel. Co., 34 Fed. Rep., 795; Siebert Cylinder Co. vs. Michigan Co., 34 Fed Rep., 33; Ladd vs. Cameron, 25 Fed. Rep., 37; Hussey vs. Whitley, 2 Fish., P. C., 120; Jones vs. Merrill, 8 O. G., 401; Potter vs. Fuller, 2 Fish., P. C., 262.

I have examined with care each of the authorities cited in the opinion of Judge Hallett, and others noted by defendants' counsel, but they do not impress me as supporting the rule held in that opinion, or as opposed to the rule pronounced in the cases above cited.

With the adoption of this rule, it is not necessary to review in this opinion the affidavits and exhibits which were before the court in Massachusetts, in the Beacon case, as a careful examination has fully satisfied me with the review and criticisms contained in the opinion of Judge Colt, and the conclusions reached by him at that stage. And of the additional evidence introduced at St. Louis, in the Columbia case, it might be sufficient to hold, in accordance with the view stated in the opinion of Judge Hallett, with which I agree, that "there is not the measure of proof demanded" by this rule. Resting upon these conclusions, it would only be necessary to consider the new testimony which has been presented here, and determine whether it has cleared the doubts which have come from the former hearings; but an understanding of the conclusions reached requires for preface a statement of some of the doubts which have been impressed upon my mind by these records.

Edison's discovery was published late in 1879. It promised an incandescent electric lamp which would supply the great want of an operative commercial light suitable for domestic uses, cheap and practical, and aroused great interest and excitement in commercial and scientific circles. Lighting by electricity had long been an accomplished fact, in arc lamps and various single burners, but the problem which had remained unsolved was a method of subdivision of the light, for which scientists in Europe and America were seeking, and which many of them pronounced impossible—an ignis fatuus. It was the solution of this problem that Edison thus announced. As stated by Mr. Justice Bradley in the McKeesport case, 40 Fed. Rep., pp. 29-31, "This was the real, the grand discovery in the art of electric lighting, without which it could not have become a practical art for the purpose of general use in houses and cities. . . We think we are not mistaken in saying that but for this discovery electric lighting would never have become a fact."

The invention claimed by Edison was a lamp which is "the embryo of the best lamps now in commercial use." The second claim of his patent here involved described it as follows: "The combination of carbon filaments with a receiver made entirely of glass and conductors passing through the glass, and from which receiver the air is exhausted, for the purpose set forth."

The thread or filament of carbon for a burner was the fundamental discovery to obtain this subdivision of electric light, for by its use he obtained the high resistance which was essential to the multiple arc system and saved from the use of enormous conductors of the electric current, the cost of which were otherwise prohibitive of subdivision. He found that for stability of this thin carbon it was necessary to have a high vacuum and remove all gases to prevent what he calls "air-washing." This led to the entire glass receiver or chamber for the lamp, and finally to platinum leading-in wires sealed into the glass, because "the coefficient of expansion of glass and platinum was the same" and the high vacuum would be retained, while iron or copper wires would destroy it. This discovery was therefore in successive steps and only as essentials for the great object of subdivision of light.

Each of these steps is claimed to have been discovered or taken by Henry Goebel many years before Edison. Against all the improbabilities of this claim, the story as related by Goebel in his several affidavits, with detailed confirmations by many witnesses, is interesting, circumstantial, and in many respects plausible, and I do not wonder that it has attracted such earnest advocacy by able counsel contesting this patent.

Henry Goebel is now seventy-five years of age, a German, came to this country in 1848, and has ever since resided in the city of New York. He appears to have been an excellent and ingenious mechanic, engaged in watchmaking, manufacturing barometers and thermometers and delicate instruments, and has shown much interest and aptitude in electrical appliances and experiments. He claims to have made incandescent electrical lamps, identical with the Edison claim in all particulars, from about 1854, and that these lamps were operated by primary batteries of his own construction, and used at his store for show and lighting in various ways, and for some time had such lamps on a wagon traveling about the streets of New York with a telescope, also of his own construction. He said he made many of these lamps each year prior to Edison's patent, and all for his own use or gratification, but not so many after 1872 as before. In 1880, and later, he was engaged in making electric lamps for the American Electric Light Company, a rival of Edison's and making similar lamps. This meagre statement cannot fairly present his story, but must suffice with mention that he was before leaving Germany very intimate with Prof. Moenighausen, who had experimented with the production of arc and incandescent electric lights, and gave him the ideas which he carried out here. Goebel does not claim that he ever worked or thought in the line of subdivision of electric lights, and the history of that art presents strong grounds for doubt.

As to the improbabilities of this discovery so long undiscovered, it is sufficient to refer to the comments in the opinions in the Telephone cases, 126 U. S.,556 ; in American Company vs. American Cushman Company, 35 Fed. Rep., 735 ; and American Company vs. People's Company, 22 Fed. Rep., 309, as well applicable here. I will refer to some of the doubts raised upon the defendants' showing as to the actual components of these alleged Goebel lamps, remarking that the testimony of the numerous witnesses, however honest, speaking of such delicate structures seen by them many years ago cannot justly be accepted as absolute verity :

1. The fundamental thread-like carbon burner of Edison only became necessary as a means to subdivision of electric light, which was not contemplated by Goebel. The latter operated with a primary battery, for which the larger "pencil" form of carbon or other material would answer as well, would be more stable and more easily made. This filament is most delicate and difficult to make, and must have a high vacuum or it will be instantly consumed. It seems unnecessary and undesirable for his purpose, and no satisfactory reason is given for its adoption by him.

2. The Goebel lamps are not shown to have had the high vacuum required for anticipation His principal statement must be taken that he exhausted his lamps by the Torricellian method in the years prior to 1879, and I think it is abundantly shown, although not without some contradiction, that such a method could not produce the vacuum necessary to prevent disintegration of the carbon ; and it seems doubtful whether it could be employed at all with this delicate carbon in the receiver. If that vacuum was wanting, the claim fails.

3. No motive is shown for such constant manufacture of these lamps throughout the years from 1854 to 1880, involving so much of time and expense, and especially of great expense in maintaining the batteries for their use, and no attempt to dispose of even one, or to utilize them for domestic purposes, excepting in a few stray instances. It seems improbable that the constant practice here asserted, and so useful for the purposes of this defense, would have been kept up without clear object.

4. Why did he not apply for a patent ? He was not ignorant of the patent laws, for in 1865 he is shown to have applied for a patent on a sewing machine hemmer, and in 1881 he is found applying for some minor improvements, one of them being a coil shown in his exhibit lamps.

5. The lamps which Goebel produced at Boston as original lamps, made in the early years, were four, called Exhibits 1, 2, 3 and 4. The first three only were produced at the hearing, with his original affidavit, the fourth being in the hands of counsel for defendants, but withheld because of doubt as to its authenticity—which doubts were afterwards cleared to their satisfaction, and this lamp then introduced by leave of court, with additional and explanatory proofs. The first three had copper and iron leading-in wires, were of what Goebel calls "meat saw" pattern, and show no vacuum now, and if fairly proved would not constitute anticipation of Edison. No. 4, called the "hair-pin" pattern, has the requisities, including a vacuum, although probably not the high vacuum. It is not now operative by reason of some defect. Goebel swears that it was operated, but experts who have examined the defect swear that it has existed from its manufacture, and it could not have operated. This lamp shows the highest excellence of the glassblower's art, is stated by experts to be beyond the ability of an amateur, and many peculiarities are pointed out in the perfect shape of the carbon, the glass bridge and position of the leading-in wires, which seem to show adoption of methods which have been produced and developed from the experience of commercial manufacture with Edison's invention. The statement as to its make, its keeping or its having been operated are not clear or convincing to the court, if they have been made so to counsel. Exhibit lamps Nos. 9 and 11, brought to St. Louis, are no more satisfactory than No. 4.

6. After Goebel's employment in lamp making by the American Company his claim of anticipation received some attention, and he had negotiations with one Dreyer in 1882 for arranging a company to exploit the claim. It failed because he was then, apparently, unable to produce an original lamp. Later it was investigated by eminent patent lawyers at various times, and apparently with great care and interest, to employ it in defenses against this patent, and also by one in behalf of complainants, and all rejected it as not well founded. Prof. Thomson, of the Thomson-Houston Company, investigated it in 1882, when it would have been of vital interest to his company to make use of it against his patent, if tenable, and after visiting Goebel he rejected its consideration. Dr. O. A. Moses, an inventor, with a similar object, visited Goebel frequently, but came to the same conclusion, and says he was unable to produce any lamp. These are potent circumstances to raise doubt.

Coming to the new testimony produced for this hearing, and which I have carefully considered, I find that the depositions of defendants are mostly cumulative, or in rebuttal of certain new affidavits produced by the complainants and not here considered, but I cannot find that they remove any of the doubts above noted.

On the other hand, affidavits now produced by complainants tend to show an admission by defendants' witness, Henry Goebel, Jr. (a son of the claimant), that he manufactured exhibit lamps Nos. 1, 2 and 3, in 1892, for the purpose of this case. There is no denial of this, but it is claimed that this son is venal and has deserted the defense to favor the complainants. One Heger, a glass blower, swears that he made for Goebel, while working with him, "in the early eighties" lamps similar to No. 4, and he thinks he made this one at that time. As to a planer which was produced by Goebel as made by him at an early day to cut bamboo for his carbon burners, one Korwan and Heger swear that it was actually made by the former in 1883. This is contradicted as to date by an affidavit produced by defendants.

Upon the whole showing, I am satisfied that the complainants are legally entitled to preliminary injunction, and that it is the duty of the court to grant it without evasion. As stated by Judge Colt, and often held, a bond by defendant is not the equivalent of the injunction which the law gives for the protection of the inventor in the exclusive privileges promised by his patent.

Injunction will therefore issue, but with leave to defendants to move for requirement of a bond by complainants to indemnify the defendants for any damages they may suffer if it shall be finally held that the patent is invalid.

Another Transmission Scheme.

Plans are well under way for the establishment of an electrical plant at Eden Falls in the Neversink River, for the transmission of power to the city of Middletown, N. Y., a distance of fourteen miles.

The line will pass through Westbrookville, New Vernon, a little north of Howells, and thence to Middletown.

The successful completion of the enterprise will enable Middletown to offer special advantages to manufacturing establishments excelled by no town in the State, and a boom should soon be apparent.

Two thousand horse power will be furnished, which can be largely increased from time to time when needed.

The name of the company backing the enterprise is the Middletown Pipe Line and Power Company, and the incorporators are W. D. Stratton, Horace W. Corey, E. A. Brown, Leander Brink, Charles H. Brink, Chester Belding, J. B. Hulett, I. C. Jordan, George S. Belding, Robert O. Lewis, H. S. Pound, George Smith, of Middletown; E. M. Willis, of New York, and Eber L. Brown, of Unionville.

Twenty-five thousand dollars of the capital stock has already been paid in.

Death of C. F. Washburn.

Hundreds if not thousands of business men in all parts of the country will learn with regret of the death of Mr. C. F. Washburn, Vice-President and Secretary of the Washburn-Moen Manufacturing Company, Worcester, Mass., which occurred a few days ago at his residence in that city, from a stroke of apoplexy. Mr. Washburn was a gentleman of great culture and refinement, interested in many public movements having for their object the bettering of society, and will long be missed. Upright and conscientious in business, he was a man with whom it was a pleasure to have dealings, while socially he was most genial in his manners and a thorough gentleman of the old type whom to know was to respect.

An Admission Fee.

New Way to Replenish the Treasury.

Large Amounts can be Raised by Extending the Rule to all Departments.

From the "Evening Telegram."

Another fact has come to my attention, and that is that General Electric is charging an admission fee of $100 in their shops at Lynn.

College men who want to get practical training have been taking a course in these shops with the idea of eventually going into the company's service. They are only paid five cents an hour for their services, which is considered very little.

Now, in addition they have to pay $100 in order to be admitted. As there is really very little chance of getting into the company through any other source, there is no way of avoiding this tax.

The revenue thus derived will make good the company's loss on a good many construction contracts.

THE CORRECT VIEW.

From the "Brooklyn Eagle."

Stocks were active and strong about 11, but soon after there was a decline under the lead of General Electric, which seemed to be affected by a movement to prevent the extension of one of the expiring patents and to bring about a prosecution of the company under the anti-trust law. The fall in this property had an unsettling effect upon the rest of the market.

Northwestern Electrical Association.

The Northwestern Electrical Association held their annual convention at Madison, Wis., last week. A large number of well-known electricians were present and the proceedings included the reading of a number of interesting papers. The following officers were elected: President, Carroll Collins, of Green Bay, Wis. ; vice-president, C. C. Page, of Oshkosh; secretary and treasurer, T. A. Pamperin, of Oconto.

Investigating the Storage Battery.

A party of city and street railroad officials of Bridgeport, Conn., came to New York a few days ago to inspect the Waddell-Enz storage battery system on Second Avenue. The new Bridgeport system will very likely be an electrical one, and the Waddell-Enz Company have expressed their willingness to file a bond for the successful operation of their storage batteries if they are awarded the contract.

The New York Board of Public Works, by advice of the Health Department, have ordered two new plants for applying Albert E. Woolf's new electrolyzing process to the purification of the Croton water. The plants will be located at the Sodom storage reservoir, which supplies thirty or forty millions of gallons daily to New York. The cost of the plants will be about $6,000. Experiments with the Woolf system have proved it a success in destroying noxious germs in water and also in its purifying action upon sewage.

ALL VISITORS to the World's Fair will be welcome at the booth of ELECTRICITY, Section Y, Northwest Gallery, Electricity Building.

Pawtucket, R. I.—The common councillors are considering the matter of establishing a municipal electric lighting plant.

The Present Condition of the Electric Trust.

No industrial stock listed on the New York Stock Exchange has been the subject from first to last of so much comment as General Electric. We print elsewhere a resumé of the comments of last week; they are all interesting, but it will be noted there is quite a variety of opinion as to the causes of the slump of 14 points net for the week, which makes General Electric a 16½ per cent. stock at the price.

The Brooklyn *Eagle's* opinion that the fear of a Congressional investigation has led some of the large holders to unload is no doubt correct, as far as it goes. When ELECTRICITY first suggested this action, it became at once apparent that we had struck a sore spot in the anatomy of the Trust. They used it as evidence of malice in their statement before the Grand Jury. The insiders well know that such an investigation would be the death-knell of the Trust.

But, as before noted in these columns, it is idle to inquire why a stock worth only $30 or $40 a share does not sell continuously for $100.

To obtain a correct understanding of the situation, it is necessary to consider the facts of history. From these facts, and from the few actual pointers which appeared among the volumes of chaff of last week's statements and comments, ELECTRICITY has constructed a theory upon which we are willing to stake our reputation, viz: That Messrs. Drexel, Morgan & Company have reached the conclusion that the management of the company is in improper hands, and that a freeze-out game is in progress on a large scale, which will result sooner or later in an entirely new management, and the relegation of the T.-H. element to private life.

It is good opinion in Wall Street that the New York bankers have become disgusted with their treatment by the Boston contingent, and that the present condition of affairs cannot last.

The facts which made the formation of the General Electric Company possible are well known to the trade. The Edison General Company had reached an unfortunate end, and could go no further. Henry Villard's foreign friends had withdrawn their support, and Drexel & Morgan, the largest American stockholders, were tired. The purchase of the Sprague railway apparatus, which had been looked to to keep the Edison Company abreast of its greatest rival, had proved a failure, because of the ousting of Mr. Frank J. Sprague, the inventor, and the ill-advised attempt to Edisonize the apparatus.

There was trouble on every hand; money could not be raised, and something had to be done to prevent the company from going into bankruptcy.

For two or three years previously the subject of consolidation had been discussed. At one time Mr. Villard had made overtures looking to a purchase of a controlling interest in the T.-H. Company by the Edison Company.

It has been stated on high authority that the professional accountants who at that time spent a week in going over the books of the T.-H. Company reported that there was no showing on the books to warrant the purchase, and that it was doubtful whether the T.-H. Company themselves knew just where they stood.

Now Mr. Villard saw an opportunity to "break even," and Messrs. Drexel & Morgan were favorably impressed with the showing made by Mr. Coffin for his company. The deal was made chiefly on this showing. And one of the first, if not the first, official acts after the consolidation was assured was the loaning of about $200,000 by the T.-H. Company to the Edison Company, part of which it is believed went to pay the last dividend of the latter company.

We believe that Drexel, Morgan & Company were deceived, not only by the showing made, but in the men they were dealing with. The unloading of stock by a Boston pool of which Mr. Coffin was a member at about 115 was perhaps not the first object lesson of the rules of conduct which seem to have governed the T.-H. contingent. Certain it is that the friction between the New York banking house and Mr. Coffin has been a matter of common gossip.

Ever since the stock began to go off, *until last week*, Mr. Coster, of Drexel, Morgan & Company, a member of the Board of Directors, has been free in his statements that the condition of the company was sound and healthy, and that New York ideas of business rather than T.-H. ideas were controlling the policy of the company. Mr. Coster assured a representative of ELECTRICITY some months ago that the stock would not be allowed to go below par, and that his house would consider the stock a bargain at par.

Nothing has done more to bolster up the stock on its various declines than these statements from the representative of Drexel, Morgan & Co. Signs have not been wanting, however, that Mr. Coster has protected himself, and that if an unhealthy condition of affairs should be developed, reaching back not only one year but six or seven years, he can place the burden of misrepresentation upon the Boston clique.

The now famous letter written some time ago by Mr. Coster to Mr. Coffin, and Mr. Coffin's answer thereto, for the innocent publication of an erroneous version of which the publisher of ELECTRICITY was indicted, were perhaps one move in this direction.

At any rate the end seems to have been reached. Both Messrs. Pierpont Morgan and Coster refused last week to say anything to reassure the company's stockholders, and referred inquirers to the officers of the company. Both gentlemen made the superfluous statement that they were still members of the Board of Directors. We say superfluous. It is thoroughly well known that they are Directors. Are we to infer that the time is near at hand when they will not be? We think not.

The only reasonable interpretation of the statement from the *Evening Post* (published in another column) is that Drexel, Morgan & Company refuse further to lend their name to the support of the stock while the company is under its present management, and while they are in position to be damaged more than any one else by the possible revelation of a condition of affairs of which they were ignorant.

It is our belief that Messrs. Drexel, Morgan & Co. were hypnotized a year and a half ago, and that their knowledge of the actual condition of affairs has been acquired by degrees; that they have reason to regret the connection of their name with the Electric Trust scheme, and that that connection, in its present form, will soon come to an end.

Upon this hypothesis it will not be long before Mr. J. Pierpont Morgan will go a-gunning in Wall Street for Mr. Charles A. Coffin; and if he fails to bag his game it will be the first failure of the kind in Mr. Morgan's history.

It is not the customary thing for a company in which Drexel, Morgan & Co. are strongly interested to go to pieces without an effort being made to save it; and we have the best of reasons for believing that after the smoke of the present battle has cleared away it will be found that Drexel, Morgan & Co. are in actual control of General Electric. Meantime the price of shares may possibly go lower still.

Now let us look at last week's developments. The debenture 5s opened at 79 and touched 68 flat, closing at 70, on sales of $122,000 for the week.

The common stock opened at 63½, touched 46, and closed at 49¼ on sales for the week of 108,502 shares.

This state of affairs shows a conspicuous lack of public confidence, but it is not alone the actual condition of the company's finances which has brought it about. Large blocks of the stock have been held as collateral on the basis of 50 by Boston banks for loans to certain members of the Board of Directors. There was a leak in these banking institutions, and the bear element in Wall Street learned of the fact. When the stock went below 50 these loans were called, and the stock was thrown on the market. It is believed that Drexel, Morgan & Co. were buyers to a considerable extent.

Rumors of a receivership have been persistent; but it is our opinion that factional squabbles between the Edison and T.-H. stockholders are doing more to render a receivership probable than the actual condition of the company at present. We believe the company to-day is solvent as to all its liabilities beyond the stock and bonds, but we do not wish to be understood as assuming that it will continue so under its present management. Meantime it is openly asserted in Wall Street that the money to pay the August dividend was borrowed, and that most of the receipts from the sale of the stock of New York and other Edison companies went to pay loans.

It is to be noted that most of the bull statements put forth by the company this year have been made by officials who know absolutely nothing about the actual condition of the company, notably Capt. Eugene Griffin, Counsellor John S. Wise and Mr. Herrick. If a reassuring statement were possible, it could be made within five hours' time over Mr. Coffin's own signature. It does not seem likely now that such a statement will ever appear, and the question arises: Is Mr. Coffin afraid to make a specific statement of actual business done, and of running expenses for the year? also that he and the other large New England stockholders have not practically unloaded?

Taking all things into consideration, ELECTRICITY sees no reason to change its views. As early as last September we asserted that the Trust scheme must go to pieces. It has already lasted longer than we anticipated. Our reasons for thinking the end is near are just what they were at that time, with some additions.

In the first place, the company never had plants or earning capacity to justify such an enormous capitalization; $12,000,000 is a fair estimate of the value of its plants, and $8,000,000 more would be ample for patents and good will; in other words, the stock and bonds of the company to-day, provided it was under capable management, would be worth an average of about 40. Further reasons for expecting an early breaking up of the enterprise were found in the fact that the company's selling expenses were extravagant, rendering it unable to compete on an even basis with its chief rivals, and that the old Edison business would naturally dissolve and scatter to the four winds before the year was over. Such has proved to be the fact. Instead of doing as much business as the combined companies did last year, they have done a great deal less. This was rendered inevitable from the fact that every man's hand has been against them; the field is full of their enemies, and their friends are limited to those who are working for revenue only. The only hope they ever had of success was in bottling up the electrical business, and competition is more active to-day than when the Trust was organized. Margins of profit are continually being pared down, and much of the apparatus of the Trust's sub-companies is out of date.

The chief additional reason which we now have for expecting a general break-up is the probable action of Mr. R. T. McDonald and the Fort Wayne Company. That they will continue much longer to work in Mr. Coffin's interest is said by those who ought to know to be impossible. The withdrawal, either of Mr. McDonald himself or of his company, would precipitate the inevitable collapse, but could only work to the benefit of the Fort Wayne stockholders.

We neither know nor care what the cash on hand of the Trust is, or what its pressing obligations are.

We do know that the formation of the Trust has proved a flat failure, and that a reorganization, a change in management and in policy is inevitable.

The utter demoralization of the Trust's securities in Wall Street, with the attendant evil effects upon the company's legitimate selling business, arousing suspicions even in the minds of its own employees, is an unanswerable argument in favor of ELECTRICITY'S *main contention for the past year, that stock-jobbing has no place in the conduct of a legitimate manufacturing enterprise.*

……o……

THE mills of the gods grind slowly, but they are grinding Trusts exceeding fine.

……o……

ELECTRICITY is feeling quite well, thank you.

The Milwaukee Case. The decision of Judge Seaman granting an injunction against the Oconto lamp company is printed in full elsewhere and is practically a repetition of Judge Colt's decision in February last. The principal point of difference between this and Judge Hallett's opinion in St. Louis is in the question of the amount of evidence and the conclusiveness which is necessary to establish defendants' case in a suit of this nature. The decision states that the Supreme Court has settled beyond dispute that for the defense of anticipation and prior use against a patent the proof must be clear, satisfactory and beyond reasonable doubt, and Judge Seaman, contrary to Judge Hallett, requires this same measure of proof in the case of a preliminary injunction.

The doubts which are raised in the decision, however, concerning the Goebel lamps will be found open to considerable criticism in the opinion of most electricians. The section of the carbon filament, it is declared, must be thread-like in order to effect the practical subdivision of the electric light, while Goebel's filaments were run on batteries for which a larger carbon would be better adapted. The degree of the vacuum in Goebel's lamps is also a question of doubt, yet neither of these points would make a lamp so made inoperative, but simply less efficient. The reason for its not being patented by Goebel seems plausible enough, as the dynamo was not invented or at least was not a commercial article, and without this the incandescent lamp would be a laboratory toy to-day.

The other objections cited are equally open to argument, and it is understood that the final hearing on this case is to come off within a few weeks. In the meantime the General Electric Company, it is understood, will proceed against some of the other companies.

……o……

Lamp Workers' Strike. Work in the fibre room of the General Electric lamp works at Harrison, N. J., was brought to a standstill owing to a reduction in the prices for piece work which were announced last week. Practically, the whole force of girls in this department, amounting to about 75, left the factory declaring it was impossible to earn a living under the new rates as only from five to seven dollars could be earned under the old prices. The reductions were from 35 cents to 25 cents on one grade, and from 25 cents to 16 and 12 cents on other grades.

While these reductions are in line with the retrenchments in the running expenses in all the departments of the company, and were to be expected, the explanation of Manager Upton of the lamp works for the new prices is worthy of attention. He is reported as saying that the move was made necessary by the competition of other lamp makers who have adopted new processes by which lamps can be made cheaper than at the Edison Works.

It appears at first sight rather strange that this company after closing nearly all its competitors' factories by injunctions should find itself so pressed by competition that it is unable to maintain its old scale of wages, yet this is undoubtedly a fact, and this part of Mr. Upton's explanation contains a compliment, probably unintended, to the enterprise of the outside manufacturers.

The fact that any standard lamps are manufactured cheaper than the Edison lamp is not evident to the consumers of these goods, as the Edison lamp has proved itself in practical use to be of about the least value of any lamp on the market, and would not be in the race at all in central station work if put in open competition with those of other makers. It is not conceivable that such lamps are produced at a greater cost than much more efficient ones, and a more probable explanation of the present reduction is the company's straitened circumstances, which condition has called for retrenchment throughout all its departments.

······o······

Storage Battery Patents. The decision of Judge Coxe filed July 18, 1893, affirming the expiration of the Faure storage battery patent in the United States, will not make the manufacture of this type of accumulator in this country entirely free, as the courts have already construed the scope of this patent to include only the application of the active materials in the form of paste, paint or cement, while the Brush patent, which is yet in force, is broader and covers all forms of active material applied to the plates except where it is in the form of paint, paste or cement, or is formed from the material of the plate itself as in the Planté type of cell.

The decision, however, opens a field in this line of business in which considerable progress may be expected, and it will doubtless be taken advantage of by the maunfacturers against whom injunctions have been procured by the company which controlled the Faure patent.

······o······

THE *Western Electrician's* extra announcing Judge Seaman's decision at Milwaukee is a bad example of the errors and inaccuracies which result from too hurried "enterprise." A careful reading of the decision furnishes no basis of fact for such remarks as these: "Goebel Defense Rejected;" "The defendant introduced the celebrated Goebel defense, and the court completely knocked it out." This sort of editorial work is either malicious or careless; we prefer to think it is the latter, as the typographical and other errors in the text of the decision itself indicate that it had not been read by any one in the office of our esteemed contemporary, not even by the office boy.

If the Goebel defense is "knocked out," it is not a "celebrated" defense. In the latter part of the report appears the following: "As to a flamer which was produced by Goebel as made by him at an early day, he cut bamboo for his carbon burners." We believe that Goebel's lamps were all good and satisfactory "flamers," but this is not what His Honor had in mind. He was talking about a planer.

······o······

NO BUILDING in this city contains half so many electric fans as the Edison Building, at 44 Broad street. They are mostly of the Lundell type, and are known to be efficient and to produce cooling breezes. Yet it is a fact that last week the officers of the General Electric Company failed utterly in keeping cool. We do not think, however, it was the fault of the fans.

General Electric.

What is Said of it Nowadays.

The Football of Wall Street, and its Friends Seem to be Dead.

New York "World."

General Electric, which in January sold at over 114, was down to 46¾ yesterday, with nearly a quarter of the sales of the day devoted to this particular stock.

Report had it that the Trust was to go into the hands of a receiver, that it was to be reorganized and that the securities in its treasury in the shape of bonds of subsidiary companies and of stock of companies which it had supplied with material were largely overrated, and that any attempt to market them would result in failure.

A leading officer of the company, to whom directors sent inquiries, said that there was no truth in the rumor that the company was going into the hands of a receiver, nor was there any reason for a receivership. Neither was there any project afoot for a reorganization. The condition of the company to-day, he asserted, is substantially the same as it has been in the past. The denial of the rumors referred to was positive and emphatic.

Boston "Advertiser."

The break in General Electric was accompanied by reports of the discharge of more men and other evidences of a falling off in the business of the company.

Russell Sage, it is said, has had 100,000 shares of stock "put" to him.

New York "Sun."

No news was obtainable either from the officers of the company or from other sources explanatory of this movement. The decline in the price of General Electric from 114 during the last six months has been accompanied from time to time by reports reflecting upon the financial condition of the company. These have been persistently denied by its officers and directors, which include a number of the wealthiest capitalists in the country. Those reports were revived yesterday and were again denied, but the denials had no perceptible effect upon the market. The judgment, as well as the instinct, of the Street is to accept the stock tape as an almost infallible guide; consequently the fact that an 8 per cent. stock sells at less than half of its par value without attracting sufficient good buying to check the decline, outweighs all that may be said in favor of the property, whether officially or by friends of the enterprise.

New York "Mercury."

Failures were reported from Milwaukee, and one prominent banking institution in New England that was said to be long of 4,000 shares of General Electric went to the wall. The question is how many firms in Massachusetts have been hurt by the rapid declines in General Electric. The stock opened at 46. It sold at 117 five months ago, so the decline has just been 71 points. The loss, assuming that the purchases were made at the high figures and closed out at the low prices, on 4,000 shares of stock, would be $284,000 in this one specialty alone.

All reports to the contrary notwithstanding, the Drexel-Morgan people are not interested in the market nor have they bought any large lines of General Electric, as was commonly reported after the close of business. The position of the Company is one of some solicitude, in thats it contracted liabilities are open to attack.

N. Y. "Morning Advertiser."

The movement was shrouded in mystery, and the officials of the company declared they could give no legitimate reason for the decline. On the Street the story was current that the company was in such condition that a receiver would be appointed. Officials say the story is absurd, and that the company has four dollars of quick assets for every one dollar that it owes.

A Bad Sign.

"Wall Street Daily News."

The General Electric Company's literary bureau has been revived, and all the news agencies are circulating the most sickening bullish guff regarding the company and its affairs. This is the same kind of stuff that was put out when the stock sold 70 points higher, and its appearance now would indicate that the insiders are not yet through selling.

New York "Evening Post."

A large part of the selling of General Electric was believed to be for the account of Boston holders, who received the stock in exchange for Thomson-Houston stock.

In the last hour there were reports that a receiver might be appointed for General Electric, and with these rumors came large selling orders. The officers of the company denied the reports and said there was not the slightest reason to anticipate a receivership.

Boston "Commercial Bulletin."

On Tuesday, while General Electric stock was declining seven or eight points, this paragraph appeared in the news slips. In fact, it is remarked by brokers on the Street that on all weak days the following kind of stuff is sent out:

> "The General Electric Company has now nearly 5,000 stockholders, and there is a steady buying of the shares for cash. The stock list shows a net gain of about 400 the past six weeks.
>
> "Orders received last week aggregated $250,000, mostly for small supplies, on which the profit is larger than upon big orders.
>
> "President Coffin says: 'If we do not fall off more than 20 per cent. in these times on our gross business, I shall be satisfied.'"

It must strike the average banker, broker or operator as a piece of exquisite irony to talk about the net gain of stockholders in any company during the past six weeks. The person responsible for these statements should come into the Street and stay there long enough to become acquainted with its ways, so that he could understand how that sort of silly-billy talk is received in panicky times like the present.

New York "Herald."

Many people were led to invest in the stock by the unusually strong Board of Directors the company possesses—men of the highest standing, and nearly all millionaires. These are Mr. H. McK. Twombly, chairman of the Board, and Messrs. J. Pierpont Morgan, D. O. Mills, C. H. Coster (of Drexel, Morgan & Co.), Thomas A. Edison, T. Jefferson Coolidge, Jr., F. L. Ames, H. L. Higginson, Eugene Griffin and C. A. Coffin. Investors, in view of constant assurances that the company is all right, are asking why some of these rich men have not hastened to buy the shares at the enormous decline represented by current prices. At these figures the stock pays sixteen per cent. on the investment, and investors argue that this should look tempting to capitalists even with money stringent as it is at present. Men who hold shares for which they paid are frightened by the fall, and fear that there must be something wrong with the company. "Is it a second Cordage Company?" is the disquieting query circulated yesterday by the bears.

The Officers of the Company Must Make the Statements Hereafter.

New York "Evening Post."

Interest on the Stock Exchange centred largely this morning in the General Electric stock, which fluctuated widely. No further information had been obtained about the affairs of the company except official reiterations of the statement that nothing was the matter with the company's affairs. A story gained credence this morning which it was said was authentic. It was to the effect that the big drop in the price of the company's stock this week was simply the result of a freeze-out. A certain clique in the company desired to get rid of some large holders of the stock and the game, it was said, was secured yesterday.

At the office of Drexel, Morgan & Company this morning it was said that Mr. Coster and Mr. Morgan were still directors of the General Electric Company. Both gentlemen, however, declined to say anything to reassure the company's security holders. They both referred the reporter for the *Evening Post* to the officers of the company for official statements about it, declining themselves to say anything personally on the subject.

The Daily "American."

The possible developments in General Electric were awaited with a good deal of interest. There is a theory in Wall Street that if a dividend stock shows persistent weakness there must be something inherently wrong with the property. If General Electric, therefore, sells below 50, Wall Street naturally argues that some of the wealthy men in the Street would be attracted to so remunerative an investment. In other words, they would buy enough of the stock to support the price in the market. In the absence of such support Wall Street feels itself privileged to hold any opinion about the property it chooses, and nobody can blame Wall Street for taking such a position.

The Faure Patent Expires.

The case of the Electrical Accumulator Company vs. the Julien Electric Company was recently admitted for rehearing upon the issue of the expiration of the Spanish patent taken out about six months previous to the United States patent.

The question in controversy was the identity of the claims of the Spanish and American patents and Judge Coxe, of the United States Circuit Court, has handed down a decision affirming this identity. The first patent taken out by Faure was in France and the subsequent patents in Spain and in the United States were translated from the French.

The decision states that "the longer the record is studied the more settled becomes the conviction that the invention which Faure patented in Spain and in the United States was the invention which he made and patented in France; that, so far as the inventor was concerned, the language was substantially identical, and that the changes in phraseology made by the translators and Patent Office officials, of which changes the inventor was ignorant, did not and could not operate to change the invention."

Electrotherapeutic Course.

A strong tide of progress in electrotherapeutics has set in during the last two years in this country, and many medical men of acknowledged standing have become so convinced of the importance of electricity in the medical practice of the future that they have undertaken a course of special study in the subject, and so been enabled to place themselves abreast of the newest and most approved practice. Many practitioners, however, are unable to avail themselves of the regular post-graduate college course, and will gladly welcome such an opportunity for tuition as is afforded by the private clinic of Dr. Robert Newman, in this city. After many solicitations from practitioners to give private lectures in electrotherapeutics, and particularly in surgical electrolysis, Dr. Newman decided to give such a course. The instruction is given in the same manner as that in post graduate colleges, except that it is private and limited strictly to a small number of students. The course consists of twelve lectures, in which clinical instruction is predominant, the modus operandi of all operations being shown. The past course has been eminently successful, and the class for the next course, which will begin on November 1, is already made up. Dr. Newman has been prominently identified with medical electrolysis, and his labors in this field for the last quarter of a century have been abundantly recognized. He has designed many of the most effective electrodes now in use, and has contributed in marked degree to the placing of electrolytic practice in medicine on its modern basis. Dr. Newman has been invited to deliver clinical lectures in electrolysis in Chicago by the Post-Graduate Medical School during the course which begins September 1.

Business Troubles.

The inventory and schedule of the assets and liabilities of Edward T. Pardee, agent of the Fort Wayne Electric Company for the State of Iowa, have been filed. The assignee is Edward C. Wright, of Syracuse. The schedule shows twenty-four creditors, among whom are Pass & Seymour for $294.38, and the Electric Engineering and Supply Company of Syracuse for $1,028.55. The amount of liabilities is $5,817.78 and the assets are $618.23, stock on hand.

Elgin, Ill.—The Dundee Rapid Transit Company expect to begin the construction of their proposed line from Dundee to this city at an early day.

Trust Methods.

The Joliet Prison Matter Causes Comment in Chicago.

How to Get a Sure Thing on a Contract.

The last Illinois Legislature appropriated $140,000 to build a modern power plant at the Joliet Penitentiary. It was intended to erect a central station, which was to furnish power to different shops by motor and steam for heating and everything else needed, and also to make provision for water power. The usual course of requiring competitive bids from various manufacturers was to be followed. In compliance with the policy pursued by all corporations when large contracts are awarded it was supposed that bids would be advertised for. Many supposed that the specifications would be advertised, as is often done. Warden Allen says they have been advertised, and he adds with refreshing innocence that they were advertised in a *Joliet paper and a weekly paper in Chicago*. It is very surprising that the advertisement in the Joliet paper escaped the notice of the manufacturers, as it is a well-known fact that the Joliet papers are on file everywhere in the civilized world, especially in Joliet!

The following abstract of the situation is gleaned from the Chicago *Tribune*, which recently devoted three columns to the matter:

Several weeks ago manufacturers began to write letters of inquiry to the Commissioners and to Warden Allen. Not until June 27 were they able to procure plans and specifications, or much information outside of these as to the character of the work to be done. Several manufacturers who wrote to Commissioners requesting interviews and an opportunity to explain their devices failed to receive replies to their letters. On visiting Joliet they found their letters in the hands of Warden Allen. On the date above mentioned typewritten specifications were delivered to them, and some of them received plans of the building and its equipments.

The blue prints furnished them bear the mark of the General Electric Company. The plans and specifications have been gone over in detail by experts of wide reputation. The specifications taken at the beginning call for four power generators of multipolar type, each 100,080 kilowatt capacity, compound wound, and guaranteed to maintain a constant potential within 2 per cent. between full load and no load, and wound so as to develop 240 volts at the brushes. The General Electric Company, or its allies, it is stated, alone makes this size generator. It cannot be made by other companies save at a large expenditure for new patterns and new machinery. It consequently would not pay any company competing with the General Electric Company to make the required changes in its plant which would be necessary if it attempted to meet this specification.

The instruments for power generators, such as switchboard, voltmeter, ammeter, are so specified as to practically cut off competition. One direct reading voltmeter is required, which is to be either the Weston or General Electric make. The Weston instruments, as is well known, sell for three times the price of those of the General Electric Company. Such being the case there could be but one result if the Weston Company put in a bid against the General Electric, as it is not probable that the Warden or the Commissioners are seeking the best in anything. Appearances indicate that they are more anxious about the margins than the quality of the apparatus. The specifications for the lighting dynamos call for two belted dynamos. The figures given are those of a General Electric machine. Two direct coupled machines are required for all night lighting, operated under one independent engine, to be either of the Sturtevant or Lake Erie Engineering Works make.

These generators are to be of fifteen kilowatts capacity, and the speed of the engine and dynamos is not to exceed 550 revolutions a minute. No maker of dynamos, it is stated, manufactures a direct connected machine of such small capacity, owing to the extreme cost if made properly. It is a machine extremely expensive to keep in proper condition, owing to its great speed. The maximum speed of ordinary dynamos is 300 to 350 revolutions a minute, but the General Electric Company manufactures a machine which makes 550 revolutions a minute.

The shafting, pulleys, details, etc., are specified, it is stated, to correspond with the manufactures of one company. Their steel plate clutches, it is stated, are alone referred to. Their work is on exhibition at the World's Fair, and in their catalogue is contained a eulogy of the General Electric Company. No bids, it is stated, are asked for shop motors, but nobody is dense enough to believe that after the General Electric Company secures the contract, motors manufactured by anybody else will be put in the shops. It is argued that after they have done the rest of the work those details will be carried out by them.

The engine called for is the exact formula, it is said, of an engine manufactured by a concern whose work is favored by the General Electric Company. An experienced engineer has said that he knew of no other engine that exactly filled the specification.

The specifications for boilers limit bidders to one of three styles, made by three separate concerns; but the plans, it is said, show conditions that fit only one make of boiler, said to be the Heine boiler. They contain just space enough for that boiler and it is drawn into the plans.

The general plans, it is stated by engineers, provide for a plant which is ten years behind the times, where the intention of the law was to provide a plant modern in every respect. As before stated, the plans bear the name of the General Electric Company. Various details of the plans are criticised. It is said while the State has plenty of room for as large a building as is needed, the space is cramped without any reason that is discernible save in following out the theory that everything has been made to fit the General Electric Company's ideas and apparatus.

One feature of the mechanical arrangement is criticised severely. The power is belted from the engine to a jack in a pit and from there to the dynamo. This arrangement, it is stated, calls for the services of an extra man, places a most important part of the machinery out of the sight of the engineer, and will, it is claimed, result in a loss of 20 per cent. to the power.

The buildings to contain the machinery, it is said, have already been started, and on plans, it is claimed, furnished by the General Electric Company.

"Such is the fact," said an engineer, "although I have not been able to ascertain what warrant of law there is for it. There can be only one inference drawn from the facts and the plans and the specifications. If I were going to erect a plant, the machinery in which was made by a comparatively few manufacturers, all of whose devices differed in certain particulars, and should draw my plans and specifications around the machinery made by one man, and then should ask for competitive bids, what sort of a reception would my invitations to manufacturers meet? They would send my papers back with notes informing me that they sought their fun on the Midway Plaisance, and had no time during business hours to pay attention to jokes. That is practically what the large electrical manufacturers throughout the country, outside of the General Electric Company, will say to the State of Illinois in this alleged competition for work. They will not bid.

" Next Tuesday, I have no doubt, there will be a number of bids there. They will be sent in by the various arms of the General Electric Company, or in compliance with understandings between that concern and others. The General Electric Company will get the work. I do not pretend to say whether or not any influences have been at work in this remarkable transaction. I will let any curious citizen guess for himself after he has examined the plans and specifications. They have been sent to many manufacturers; some of them keep them as curiosities."

A representative of one of the largest electrical concerns in the country is quoted as follows by the Chicago representative of ELECTRICITY. He said: " I wrote to the warden of the penitentiary several weeks ago in regard to the plans and specifications, but received no answer. I wrote again and then telegraphed him twice, but could get no reply. I called on him personally and found that he had received my letters and also telegram, but gave no excuse why he did not answer them. He promised to send me plans and specifications as soon as they were ready, but I have not received them up to date. On my arrival in Joliet, I was confidentially informed by an employé that I was too late (this was two weeks before the date set for opening the bids) to get in a bid. The warden could not have gone to much trouble to find an engineer that would fill the position he wanted. I suggested the following men: Frank B. Rae, of Detroit; D. L. Barnes, of Chicago; C. G. Armstrong and Gustave Monrath, also of Chicago. These men are not connected in any way with electrical companies. I would bid on specifications furnished by any of the above men, but would not bid on specifications furnished by the General Electric Company."

We are informed that Warden Allen was formerly the manager of the Thomson-Houston station at Joliet. In his own defense, Mr. Allen says:

" I went to Chicago and looked for an engineer to draw plans for the plant. *I could not find a man whom I thought was absolutely independent.* I called on the General Electric people in Chicago, and spoke of my difficulty in finding an engineer. They suggested that the plans be drawn by their engineering department, and I agreed."

The italics are ours.

On Tuesday, the 18th, the bids, twenty in number, were opened in the presence of representatives of the various manufacturers. Most of the bids were on different parts of the plant only.

Mr. C. A. Daigh, representing Siemens & Halske, made the following remarks to the Commissioners :

" I am here, representing a large concern, and taxpayers besides, who are not satisfied with the method of letting this contract. We propose to have something to say before this plant is installed. I saw the plans for the first time to-day. They do not provide for the cheapest plant that can be put in. Our company, one of the largest in the world, will guarantee to save the State from 12 to 20 per cent. in a plant properly planned. I protest against the methods which have been used. I have written and wired the Warden and the Commissioners concerning the work without securing information, and did not know until a day or two ago that you would open the plans to-day. I ask that these specifications and plans be set aside and that five or six engineers be selected to make plans. Our company will undertake to pay them if the engineers are independent."

The Commissioners then sent to Chicago for an expert to analyze the bids.

The three bids on the complete plant were as follows : Westinghouse Company, $56,300 ; Waddell-Enz Company, $56,552 ; General Electric Company, $58,458.

The Philadelphia Trust in Trouble.

The minority stockholders have filed an application with the Chancellor of New Jersey for a receiver for the Penn Electric Light Company of Philadelphia.

The Chancellor is asked to declare the trust under which it is claimed the stock is voted illegal, and to restrain the Guarantee Trust and Safe Deposit Company from voting the deposited stock, and to restrain the Electric Trust of Philadelphia from voting the stock alleged to be held by it.

The bill also asks to have the Electric Trust of Philadelphia pay the stockholders of the Penn Electric Company what they should have received for the use of their conduits had they been rented to other companies besides the Edison Company.

Electric Plant for Cape Town.

An important electrical project is to be undertaken in Cape Town by Siemens & Halske, of Berlin. Three tenders were made by this company, one proposing alternating currents with transformers, the second, accumulator substations with three-wire system, and third, an accumulator substation with the five-wire system, which latter was accepted owing to its strong recommendation by the company. The power will be supplied from a neighboring river from which a pipe line 4½ miles in length will convey the water to the power house, a fall of 1,350 feet being available. The dynamo will be directly connected to two turbines running at 250 revolutions per minute. The current is then to be led to the substation in the town from which the distributing system is supplied. There will be 22½ miles of underground conductors and 152 miles of overhead wires. The system is to be in operation by December of next year.

An Electrical Railway Switch.

In a former issue we published a paragraph announcing the invention of an electric railway switch, a fuller description of which we are now able to furnish our readers. The purpose of this apparatus is to place the control of the switch tongue in care of the motorman on every electric car, thereby allowing both motorman and conductor to remain at their posts on the car when approaching switches. As is well known, the cost to railway companies of keeping men at important switches in large cities is very great. There are about eighty men so employed in Boston alone. This new device is operated by electricity taken from the trolley circuit. The entire mechanism is placed in a water-tight box beneath the road bed. On the approach of a car contact between the car and the device is obtained by means of brushes that are lowered from the platform of the car by a motion of the foot of the motorman. It consists of electro-magnets arranged in the box and attached to the switch tongue. Elongated strips are connected by an insulated cable or wire with these electro-magnets, and sufficiently in advance of the switch to be in sight of the motorman. These strips are placed between the rails of the track and insulated from the ground and from each other. As the car approaches, should the switch tongue need to be thrown, the motorman simply presses his foot, makes the connection between the car and the electro-magnets, and instantly the switch is thrown and held in position until the car has passed the switch. This device has been invented and patented by Mr. Edward Stone, of Hyde Park, Mass., who is in correspondence with several railway companies with a view to its adoption by them.

Rockford, Ill.—The Strowger Automatic Telephone Company have been granted a franchise to place a system in Rockford.

Electric Light at the Krupp Works.

The electric light plant at the Krupp works, in Essen, which was commenced in 1876, has recently received considerable extension. The generating station is situated near the centre of the works, and includes six dynamos and steam engines of an aggregate of 650 H. P. There are two separate systems of distribution ; one at 100 volts, continuous-current, for the glow lamps in the offices and workshops ; and the other at 700 volts, continuous-current, for the arc lighting circuits and, by means of continuous-current transformers, for the more remote glow lamps. The low-pressure circuit consists of 3,200 metres of underground cable, feeding 1,400 glow lamps. The high-pressure cables are conveyed from the central station to three distributing stations at a distance of 4,900 metres, whence they radiate to the numerous arc lamp circuits which are carried overhead. Each of the arc lamp circuits consists of 16 lamps in series, and supplies 10 amperes. There are 384 arc lamps on all the circuits.—*Electrician*, London.

Long-Distance Telephones.

It has been decided by the Pennsylvania Railroad Company, after careful consideration, to adopt the long-distance telephone for communication between its principal executive offices in place of the telegraph system. The new system is to be used, however, exclusively by officers of the company, and will be of especial value in transacting confidential business. Mr. Chas. E. Pugh, third vice-president, has developed the system and arranged for its installation, which will connect the offices in New York, Jersey City, Baltimore, Chicago, St. Louis and other important points.

No one will have access to these telephones except the higher officials, not even for the purpose of communicating with an officer.

Boston Notes.

Mr. Frederick S. Minott, the enterprising general manager of the National India Rubber Company—whose factory at Bristol, R. I., is the largest of its kind in the world and employs over 1,300 hands—is to be congratulated on the prosperous condition of the gigantic business that he so ably manages. He reports that trade could not be much better with his firm, for they are working every department full blast and have orders ahead already that will last them well into fall, and they keep rolling in every mail. Founded in 1825 the works were never in better order than now nor the goods manufactured in greater demand, and this notwithstanding the competition in their special line.

A sad case of poisoning from an overdose of what is known as wintergreen—the essential oil of Gaultheria—was that which occurred in Lynn, Mass., last Thursday afternoon, the victim being Arthur Thaddeus Woodward, inventor and patentee of the Woodward Underground Electric Light and Cable Company of New England. Mr. Woodward was quite an inventor and is said to have been the first manufacturer of wooden toothpicks in this country, out of which he made a large fortune which he got through in double quick time. His system of underground conduits for electric wires and cables had excited much interest at times in different parts of the country, and had the inventor himself taken care he might have achieved success with it. Unfortunately, he had long been addicted to excessive drinking, and it was during a fit of temporary insanity that he committed the rash act that ended his life as stated above.

Mr. Henry Kaliske, general manager of the Beacon Vacuum Pump and Electrical Company, of Boston, is taking a brief rest, accompanied by his wife, at Long Branch, N. J. Mr. Kaliske is an indomitable and successful worker, and being somewhat under the weather, or as he is accustomed to say " no better," has hied himself away for a brief respite.

Mr. A. D. Claflin, of the firm of Claflin & Kimball, who represent the Mather Electric Company and the Waring Electric Company, has just returned home after several weeks' sojourn in Chicago. He has done the World's Fair pretty thoroughly, and like everyone else who has been there considers it "the biggest show on earth."

The New England Electric Heating Company, Boston, has just issued catalogue No. 1, in which appears cuts of its various devices. This company is now doing quite an extensive business in the manufacture of almost every conceivable article, utensil, tool or appliance that requires heat for its use.

The monster electric locomotive which has just been built by the General Electric Company has this week been shipped to Chicago, and will on arrival be put on regular service. It weighs thirty tons and is expected to develop a speed of thirty miles an hour.

There has been a misunderstanding or a disagreement between the Lynn and Boston Railroad Company and the Selectmen of Melrose for some time past which has prevented the electrical equipment of the road between Saugus and Melrose. An agreement has at last been reached between the two bodies and the road will be proceeded with at once. When the road is completed it will prove a great boon to residents en route, and open up a wide and attractive suburban district which hitherto has been lacking first class traveling facilities.

A novel race meeting is being arranged by the Malden Bicycle Club to take place on Monday evening at the race track in Waltham. The entire bill of sports will be gone through in a brilliant manner after dark, and will be an electric race meeting. Arc lights are being installed all round the track in a similar manner to that adopted some year or so ago in St. Louis. A large gathering of spectators and flyers is expected, and without doubt it will prove to be a great occasion with brilliant results to all parties in interest.

What with the extraordinary fall in the price of its common stock, the same having touched 48½ on Thursday, the closing of its extensive new foundry because of the cost of production being found to be more than castings can be purchased for from outside firms, and the reported laying off of nearly 1,000 employes hitherto engaged in its Lynn factories, the General Electric Company is moving through troubled waters at present, and people are anxiously asking, "What is the matter?" Of course the general demoralization that prevails in the stock market is simply being shared in by the General Electric Company, but the other facts to which we have above alluded induce outsiders to believe that there is something the matter that doesn't quite appear on the surface. Just what that is, is what many would like to know. The favorable decision handed down on Thursday at Milwaukee, sustaining the validity of the Edison Incandescent Lamp patents in the suit against the Oconto Manufacturing Company, ought to assist the Trust somewhat, as ought also the despatch received in Boston Friday from Mr. C. A. Coffin, stating that the liabilities of the Trust are only 23 per cent. of its quick assets. Still it is generally doubted hereabouts whether public confidence will be permanently restored. The general feeling is that the company ought to come right out with a full and explicit statement of its exact standing, such a statement as everybody can understand, and so place itself squarely before the stockholders and the public generally. Until that is done, rumors, suspicions and fears will abound.

So rapidly is the business of the Edison Illuminating Company of this city growing—and already the volume of business done is colossal—that the directors are asking authority to increase its capital stock by $500,000—it is now $3,000,000—to enable it to increase its plants and to extend its underground system. As soon as the authority is obtained the company will go ahead, and complete what it has in contemplation to do.

Notwithstanding the general depression that prevails, there are several electrical firms in Boston that report more business than ever, one or two even declaring that collections are as good as ever they were.

General News.

What is Going on in the Electrical World.

New Orleans.—The St. Charles Street Railroad Company intend to change their line into an electric system.

Xenia, Ohio.—Mr. Neff has applied to the city council for right of way for an electric railway on Detroit street in this city.

New Albany, Ind.—The city council has given the Glenview Electric Railway Company one year longer time in which to build their road.

Jersey City, N. J.—The New York and New Jersey Telephone Company have begun putting their wires underground in this city.

Knoxville, Tenn.—The West End Street Railroad Company is showing commendable energy in replacing the old horse cars on its road by electric cars.

Oneida, N. Y.—The Oneida Railway Company's application for change of motive power on its line to electricity has been approved by the State Railroad Commission.

San Francisco.—The creditors of the San Francisco and San Mateo Railway propose to take immediate steps to liquidate the company's indebtedness and complete the road.

Cincinnati, O.—The Fort Thomas Electric road will be extended one mile beyond the fort, thus making fifty miles of track the Cleveland syndicate has laid at a cost of $1,972,000.

Niagara Falls.—The local Brush Electric Light Company has sold its plant to the Buffalo and Niagara Falls Electric Light and Power Company. The latter takes possession Oct. 1.

Toledo, O.—The city council committee on gas and light have made a recommendation that the city should provide its own plant for public lighting. The suggestion meets with approval.

Philadelphia.—The stockholders of the Frankford and Southwark Passenger Railway Company have voted to lease the property and franchises of the company to the Electric Traction Company.

Springfield, Ohio.—An electric line is being constructed from Magnetic Springs, north of Springfield to Columbus, by E. R. Hotzenpiler, of this city. He intends furnishing power and light to towns on the route.

Lockport, N. Y.—The proposed electric railroad between this city and Buffalo by way of Williamsville and Swarmsville is receiving much encouragement. At the first meeting held in its interest here about $12,000 was subscribed.

Columbus, Ohio.—The new Columbus and Westerville Electric Railway Company have begun work in earnest, and will push the work of building the road. The double pole system will be used, power being furnished from Columbus.

Oakland, Cal.—The East Oakland Street Railway Company has been granted a fifty years' franchise for an electric railway line extending through a number of streets near the city limits, with the right to carry freight as well as passengers.

Newark, N. J.—The force of the Westinghouse Electric Manufacturing Company has been materially reduced at the works here on account of over production. The men discharged were assured by the manager of the works that they would be re-employed in a short time.

Rochester, N. Y.—The water pipes in the vicinity of the Rochester Railway Company's power house on Centre street were recently found rotted at one end. Chief Engineer Kuichling ascribes this to the action of electric currents from the power house.

Albany, N. Y.—The Hudson River Telephone Company and the Union Telephone Company of Saratoga County have consolidated, the former company having purchased all the shares in the Union Company that were not already owned by the directors of the Hudson River Company.

Findlay, Ohio.—The contracts for city lighting for five years have been let. The arc contract was let to the Hancock Electric and Power Company for supplying the 135 arc lights used, while the incandescent contract was awarded to the Findlay Company.

Schaghticoke, N. Y.—The Schaghticoke Powder Company has entered into a large contract with New York parties for erecting an electric plant for light and motive power at the works. Five mills will be fitted at once with machines for that purpose. It is expected to have the plant in operation by November 15.

Utica, N.Y.—An electric road from this city to Sylvan Beach on Oneida Lake is a scheme that is meeting with much favor among the people along the route. It will probably be built. The entire length of road to be constructed under the proposed plan would be sixteen miles for a total length of twenty-six miles.

Bridgeport, Conn.—The Bridgeport Railway Company, the Bridgeport Horse Railroad Company, and the East End Railroad Company have consolidated under the name of the Bridgeport Traction Company. The capital of the new corporation is $2,000,000. The roads will be operathe by electricity.

Pueblo, Col.—The city council has granted right of way for poles, wires, etc., to the Land, Water and Power Company, the franchise to run twenty years. The company will give a $25,000 bond for the completion of its water power electric generating plant at Rock Canon and its readiness within a year to furnish power within the city.

Frederick, Md.—The construction of the electric road from Middletown to this city is, according to the terms of the contract, to be completed by October 10. The road will afterward probably be extended north by way of Mechanicstown and Emmittsburg, to connect with the electric road in course of construction on the battlefield of Gettysburg.

Drifton, Pa.—Coxe Brothers & Company are having an electric railway built from Buck Mountain, where a 40-foot vein of coal has been discovered, to Eckley, a distance of four miles. The same company, it is stated, intend fitting some of its collieries with electrical appliances for pumping, ventilating and other work, doing away entirely with steam power.

Duluth, Minn.—The Hartman Company's proposition to reduce the price charged the city for street lights about 15 per cent. on condition that its present contract be vacated and a new one executed to run for a period of five years from July 1, 1893, has been agreed to by the city council. The provisions of the contract will extend to West Duluth when that village becomes a part of the city.

Orange, N. J.—The Newark *Call* states that the Essex County Electric Company of Orange, which has had a practical monopoly of electric lighting in the Oranges, has just got ready to make an important change in its system for incandescent lights. It is the abandonment of the Heisler system of electric lighting and the substitution therefor of the Westinghouse multiple system.

Pottsville, Pa.—The building of the Beaver Meadow, Hazelton and Mahanoy City Electric Railway, one of the longest electric roads in the State, will again be prosecuted. The preliminary injunction against it for occupying or infringing on public roads of Schuylkill County has been discharged. The road will be run from Beaver Meadow to Mahanoy City, and thence probably to Pottsville, a distance of about forty miles.

Brattleboro, Vt.—The electric light company have just finished and will soon occupy their new power station. The building is of brick, one story high, with a large basement, and is 50 feet square. It will be furnished with five dynamos, a Rollins engine of 150 horse power, a Fitchburg engine of 150 horse-power and two large boilers. In addition there is a 21-inch wheel, which, as there is abundant water power, can be used to run the machinery.

St. Joseph, Mo.—The deed conveying the property of the People's Street Railway, Electric Light and Power Company from Master in Chancery Crandall to Frederick P. Olcott, chairman of the reorganization committee, thence to the St. Joseph Traction and Lighting Company, has been filed in the county recorder's office. The new company will issue $1,100,000 worth of 5 per cent. ten-year gold bonds, and have placed a mortgage on the property with the Central Trust Company of New York for that amount.

Sharpsburg, Pa.—The charter granted to the Allegheny and Kiskiminetas Electric Railway Company is for a road fifteen miles long, from Etna Borough to Sharpsburg, and connecting Aspinwall Borough and Hites Station in Deer township. The capital stock is $700 000. T. H. Hicks of Philadelphia, is the president, and the directors are Ezra Lukens, A. P. White and F. A. Phillips, of Philadelphia, and J. R. Davis of New York City.

Toronto, Can.—The Toronto Street Railway Company has had considerable trouble with its motors, and has decided to change them. The result is that Messrs. Ahearn & Soper, of Ottawa, have received orders during the past thirty days from the Montreal and Toronto companies for $150 000 worth of electric motors, dynamos, street cars, etc., the work on the main portion of which has been done in Ottawa. The new system of motors used by Toronto will be the Westinghouse.

Brooklyn, N. Y.—The effect of the competition of the trolley cars on the elevated roads of Brooklyn is plainly disclosed by the statistics of travel on the latter during the period of the operation of the trolley on the surface lines. During the last 23 days of June and the first 13 days of July there were 126,750 less passengers carried on the Kings County Elevated than in the corresponding period of last year. This is an average loss of 3,520 passengers a day. On the Brooklyn Elevated Railroad there was a corresponding loss.

Harrison, N. J.—Seventy-five girls employed in the fibre department of the Edison General Electric Light Works in Harrison struck last week against a material reduction of wages. The girls work piece work. It was understood that the company, after careful consideration, agreed upon the necessity of the reduction because of competition with other lamp makers, who had adopted new processes by which lamps could be made cheaper than at the Edison works.

Milwaukee, Wis.—The Milwaukee Electric Power and Lighting Company, according to the *Sentinel*, is to be reorganized. George Hiles holds a mortgage of $25,000 on the property of the company. It is proposed by reorganizing to lift this mortgage. The company has a capital stock of $150,000, only $60,000 worth of which has been sold. This stock will be assessed 50 per cent., and new stock will be issued to those who will subscribe to the assessment. Those who subscribe to the assessment will be kept in the company and those who do not will be dropped.

Duluth, Minn.—The new power station of the Hartman Electric Company is completed. It has some features worth noting. The building is 125x105 feet. The boiler, shaft and engine rooms are all isolated. There is an aggregate of 1,900 horse power generated by five engines. There are three classes of dynamos. The stack is of steel lined with brick for 200 feet above the foundation and tapers from 18 to 8 feet in diameter. The cost of the building was $60,000 and the machinery cost as much more.

Harrisburg, Pa.—A proposition has been made to the city authorities by a firm dealing in electric supplies to build an electric plant, erect poles, string all the wires and in fact equip an entire plant, if the city will pay to the company $36,000 per year, the sum it now pays annually for its electric light, for five years, at the end of which time the company will turn it over to the city to be run and controlled as city property. This company also proposes to build and equip a plant and turn it over to the city for $150,000 as soon as completed.

Hartford, Conn.—The *Post* of the 12th inst. draws this comparison of the two methods of electric propulsion which have been proposed for adoption on the lines referred to, and caused much discussion in official quarters: "Suppose the storage cars could run even on the Parkville line or the Farmington avenue line, they cannot draw 'trailers.' It takes two tons of cells to propel an ordinary car. Yesterday a trolley car left the city with five loaded cars attached to accommodate picknickers. It would have taken twelve tons of Usher cells to take the same load by storage with no open cars at that."

Lancaster, Pa.—A mortgage for $700,000, given by the Pennsylvania Traction Company to the Provident Life and Trust Company of Philadelphia has been filed here. The mortgage states that the Pennsylvania Traction Company proposes to include in its line the Lancaster and Philadelphia Electric Railway line, which will extend from Philadelphia to Harrisburg via Malvern, Downingtown, Coatesville, Parkesburg, Lancaster, Mount Joy, Elizabethtown and Middletown. The mortgage is given on all the electric and motor power and passenger railways contained in the company's system in Dauphin, Lancaster, Chester, Delaware and adjacent counties of Pennsylvania.

A Great Building With a Strange Name.

The term rookery suggests to the imagination a structure with yawning gables and a roof line as uneven as the back of a Bactrian camel—a tenement deserted by human occupants, and given over to the winds of heaven and the fowls of the air—a place such as Dickens delighted to invest with a weird and romantic interest for the edification of his Christmas readers;—but the building known by that name and situated in the heart of Chicago effaces such a fancy as soon as seen. It belies its title and presents no incongruous aspect amid the majestic piles that rear their fronts in its neighborhood. The present Rookery occupies the site where ten years ago stood the old and ricketty City Hall, at that time aptly named the Rookery, not only because of its general uncouth appearance, but as being the "forum," or jaw-shop, where in shiny broadcloth the "city fathers" and other crafty politicians assembled to expound their views on the sublunary concerns of the rapidly expanding municipality or to discuss ward problems which they could not solve "individually by thimselves alone" (as some of them may have remarked).

The Rookery of to-day as described in a neat brochure by George Cutter is one of the finest edifices in Chicago, although a pioneer among the modern office buildings. "Its construction, arrangement and careful management," Mr. Cutter says, "all suggest the opposite of its historic name." Its location gives it pre-eminence as a business building, being near the Post-Office, Custom House, Board of Trade and Grand Pacific Hotel. It is the centre of a circuit formed by the railway passenger depots, and is convenient to the prominent hotels, stores and warehouses. Several street car lines pass its doors, and others are nearby. "It is," says the writer of the pamphlet, "a nucleus for engineering and commercial work—a little business world in itself. The four thousand occupants, representing a hundred different lines, make the building quite a city. Ten swift passenger elevators give ready access to all its floors, while four hundred telephones and two telegraph offices keep up close connection with the outer world." The building is 175 feet square, with 900 rooms. In it are four banks, large safety deposit vaults, four express companies, the offices of a dozen railroads, several street car lines, lunch rooms, cigar stands, barber shops and other conveniences; but it is, perhaps, as an electrical headquarters that the great building more particularly commands the interest of our readers, and well it may, for in it are the offices of firms that control the lighting of a score of cities with a total of 5,000 arc lights, and 150,000 incandescents. Scores of electrical engineers, contractors, dynamo builders and dealers have offices in the building, and electrical and other trade journals have their representatives within its walls.

Among the most surprising things in connection with the building are its shipping facilities which are fully adequate to the requirements of the numerous occupants who have to send off their goods with dispatch.

Mr. Cutter well says there is considerable inspiration in being within a building animated as The Rookery is by a thousand active interests. Here he himself is congregated with his "pet specialties," devising new ones, filling orders for those already in favor, and doubtless contributing not a little to the inspiration he speaks of. The pamphlet is well worth reading, and we advise all who wish to get a fuller account of the famous building to procure a copy from its author, Mr. George Cutter, whose wide-spread trade in electrical appliances makes him one of its busiest tenants.

COMMERCIAL PARAGRAPHS.

The Railway Equipment Company, Pullman Building, Chicago, claim to be the only company in the United States making an exclusive business of manufacturing electric railway supplies. They furnish everything used in the electrical equipment of railways, and in the circular at hand call special attention to their Straight Line Insulator and Chicago Clamp, for which they have applied for a patent. Years of time and attention to the wants of *electric roads only* warrant the company in stating that they furnish "the most simple, effective and economical line devices manufactured." Their catalogue can be obtained on application to W. R. Mason, general manager, as above.

The Ansonia Electric Company are receiving orders for the V. W. Lightning Arresters and Wirt Dynamo Brushes from New Zealand, England, India and other foreign countries, which would seem to prove conclusively the sterling merits of these goods.

The Lundell Exhaust Fan Outfit for ventilating dynamo rooms, etc., can always be installed in a manner to obtain the best results by having an outfit in either end of the dynamo room, one to draw in cool air and the other to drive out the hot, thus keeping a constant change of air. Such an installation should be made so that the hot air is driven out through the street ventilators in the side walks. Hot air should not be driven into ventilating shafts. The motors are reversible so that the air can be taken from either side of the building depending upon the direction of the wind, thus insuring a perfect ventilation.

INCORPORATIONS.

The Seashore Electric Light and Power Company, Asbury Park, N. J.—to make, sell and furnish electricity for lighting, heating and power. Capital stock, $250,000.

The Miller Electric Company—to manufacture electric and mechanical appliances in New York City. Capital stock, $5,000. Directors: Sylvanus R. Miller, of Brooklyn; S. Shethar and P. Shethar, of Newcastle, Westchester County, N. Y.; E. A. Nichols, of New York City, and Charles H. Coffin, of New Rochelle.

Articles of association of the Buffalo City and Zinc Belt Telephone Company have been filed in the office of the Secretary of State at Little Rock, Ark. The business of the company is to operate and maintain a system of telephone lines through Independence, Stone, Izard, Fulton, Baxter, Marion, Searcy, Boone and Carroll Counties, Arkansas. Capital stock, $5,000. President, James Mix; secretary, Geo. Emmart, and treasurer, E. L. Hayes.

The Duplex Trolley Company—to manufacture electric machinery and appliances in New York City. Capital stock, $10,000. Directors: C. E. Chinnock and Joseph Bruns, of Brooklyn; D. E. Rose and L. Beyer, of New York.

The Schoharie Telegraph Company—to construct a line between Schoharie and Central Bridge, N. Y. Capital stock, $500. Directors: D. S. Mayham, Phillip Dey, George Taylor and others, of Schoharie.

The Santa Monica Electric and Power Company, Santa Monica, Cal.—to manufacture and deal in electricity for all purposes. Capital stock, $40,000. Promoters: H. V. Carter, Los Angeles, Cal.; F. W. Carter, Santa Monica; A. Steadman, Monrovia, Cal.; J. J. Davis and H. A. Winslow, Santa Monica.

The Hubbell Improved Battery Company, Portland, Me.—to manufacture and deal in electric batteries and machinery of all kinds. Promoters: Chas. J. Hubbell, Geo. H. Gardner, Samuel A. Fuller, James A. Riedel, Boston, Mass.

The Dubuque Light and Traction Company, Dubuque, Iowa—to construct, maintain and operate electric light and street railway plants. Capital stock, $600,000. Promoters: James S. Cummins, Walter J. Ballard, Edgar A. Duncan, Geo. K. Wheeler, John L. Martin, Dubuque, Iowa.

The Willamette Falls Company, recently incorporated, is an auxiliary of the Portland (Ore.) General Electric Company. The officers are: P. F. Morey, president; H. W. Goode, vice-president; C. H. Canfield, secretary; Chas. P. Thore, manager.

The Centralia Light and Power Company, Centralia, Ill.—to manufacture and sell gas and electricity. Capital stock, $31,000. Promoters: Seymour Andrews, F. Kohl, Geo. L. Pittinger.

The Technic Electrical Works, Camden, N. J.—to manufacture and repair electrical and other machinery, apparatus, etc. Capital stock, $20,000. Promoters: D. Pepper, Jr., A. L. Register, Philadelphia; J. J. Zimmele, Camden.

The Middletown Pipe Line and Power Company, Middletown, N. Y.—to utilize the water power of the Neversink River in generating electricity for transmission to Middletown for lighting, power and all uses to which electricity can be applied. Capital stock, $50,000. Incorporators: W. D. Stratton, H. W. Corey, E. A. Brown, Leander Brink, Charles H. Brink, Chester Belding, Geo. Smith, Eber L. Brown, of Unionville; E. M. Willis, Dr. J. B. Hulett, I. C. Jordan, Geo. S. Belding, Robert O. Lewis and H. S. Pound.

The Sioux City Electrical Supply Company, Sioux City, Iowa—to manufacture and deal in electrical machinery and supplies. Capital stock, $100,000. Promoters: H. D. Woodruff, S. G. Nelson, Sioux City.

The Nordlund Arc Lamp Company, Seattle, Wash.—to manufacture and sell arc lamps and electric appliances, own and operate plants for the purposes of furnishing electricity for lighting and other purposes. Capital stock, $15,000. Promoters: Andrew Chilberg, Robert J. Wilson, A. Amunds, L. B. N. Nordlund, Peter Wickstrom, Chas. A. White, Seattle; C. M. Nordlund.

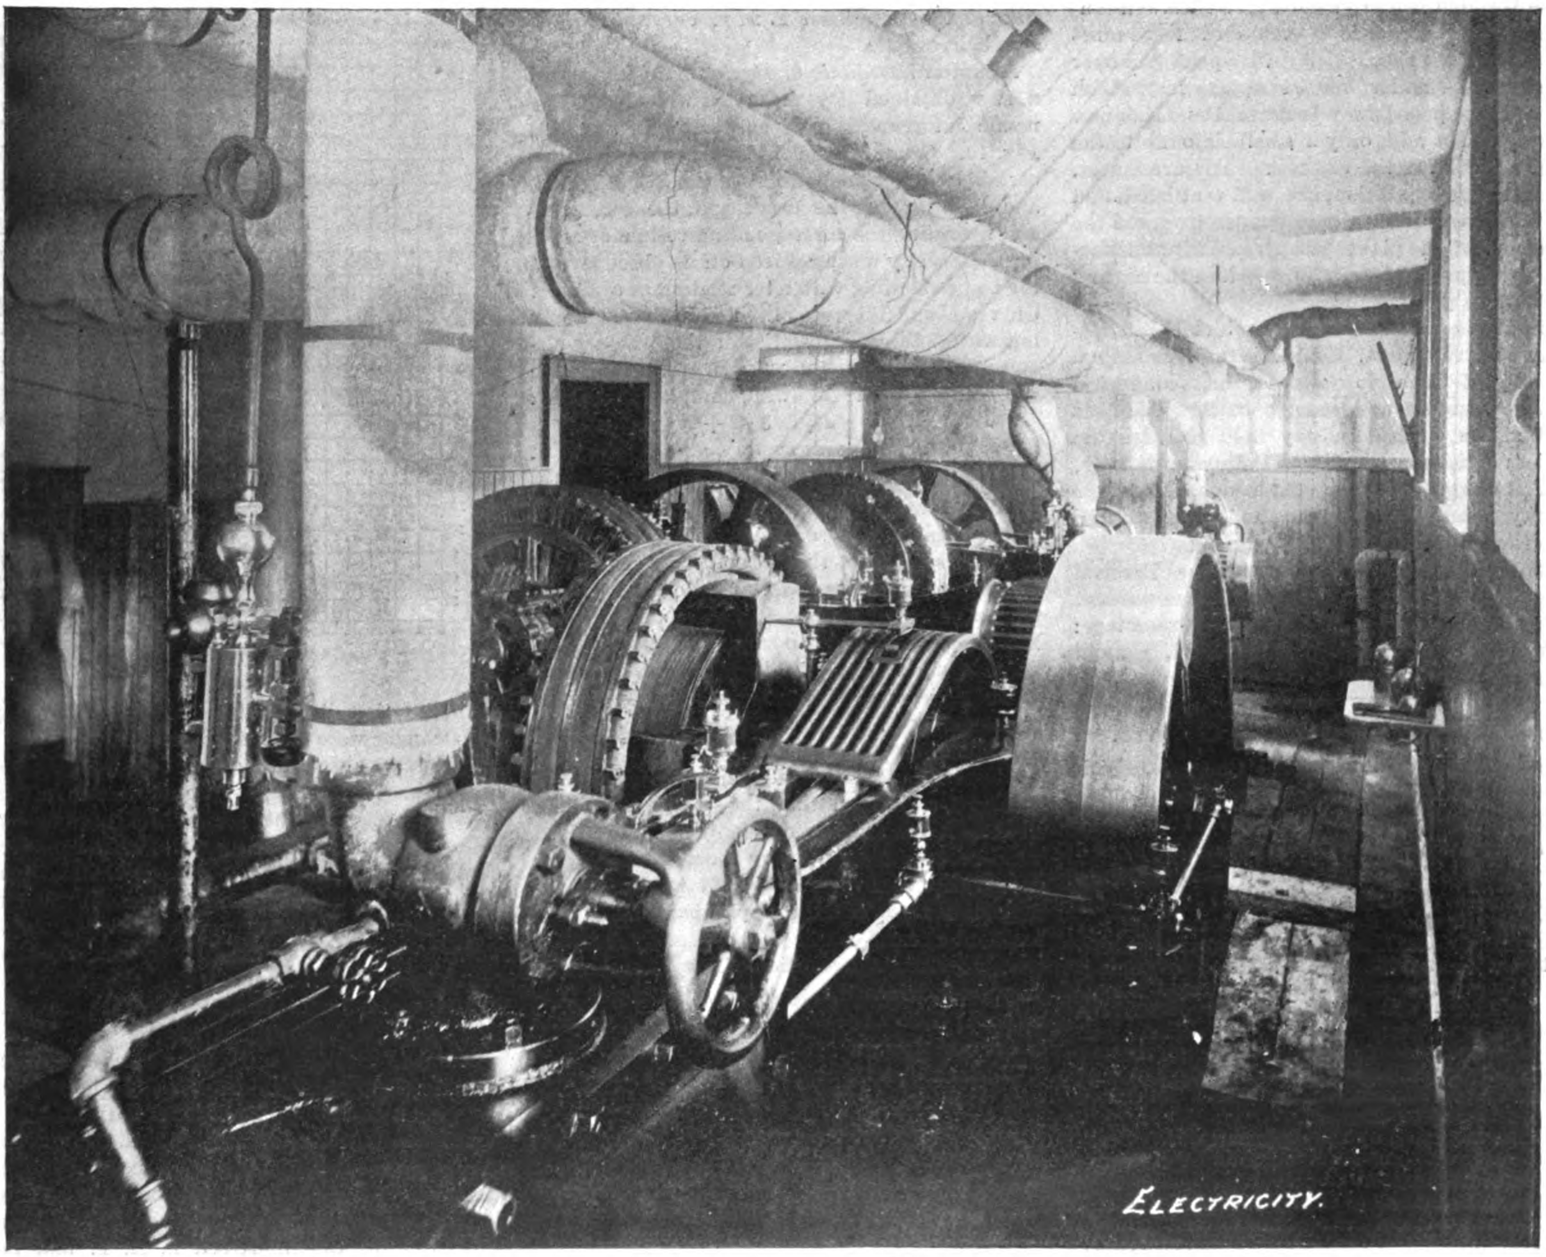
The Baltimore, Middle River and Sparrow's Point Railroad Company, Baltimore, Md.—to construct and operate an electric railway between Baltimore and Sparrow's Point. Incorporators: Thomas B. Gatch, Levin F. Morris, Frank W. Trimble, John J. Forrester, James Sloan Hoskins and George R. Willis.

The stockholders of the recently incorporated Electric Traction Company of Philadelphia have decided to increase its capital stock from 1,000 to 50,000 shares of a par value of $50, making the capital $2,500,000.

The McMinnville and Smithville Electric Railway Company has been chartered at Nashville, Tenn., to construct and operate an electric railway from the depot of the Sparta branch at Nashville to Smithville, in DeKalb County, thence to the Nashville and Knoxville Railroad at a point near Silver Point and also to Brush Creek in Smith County, with lateral branches connecting with the main line. The incorporators are; W. G. Crowley, J. L. Calvert, A. B. Hooper, Z. P. Lee, B. M. Webb, T. B. Potter, E. J. Evans, W. A. Johnson, A. E. Potter, J. C. Webb, J. J. Smith, P. A. Pearson, John T. Potts, D. Osborn and J. L. Murphy.

ELECTRICITY.

VOL. V. NEW YORK. AUGUST 2, 1893. CHICAGO. No. 3



WADDELL-ENTZ PLANT, HOTEL WINDEMERE, CHICAGO. (SEE PAGE 26.)

The Hotel Windemere Plant.

The Waddell-Entz System Installed in Chicago.

The Waddell-Entz Company, which has become known as one of the successful introducers of storage battery systems, is now pushing its business in the line of dynamos, and the plant recently installed in the Windemere Hotel, Chicago, is one of the first of this kind to be used in the West, and illustrates the type of machines of which this company makes a specialty.

These machines, as will be seen in our Frontispiece, are of somewhat unusual construction, the pole-pieces being surrounded by the armature which acts as the fly-wheel of the engine, to which it is directly connected. The machine has six poles of soft cast steel, and only a single coil is used for the field winding. This coil contains both a shunt and series winding, and is placed against the yoke inside of the projections forming the poles. This frame is fixed rigidly to the engine frame, and the armature is placed upon the engine shaft, thus making a very compact and solid construction. The commutator carries six brushes which are connected in multiple.

The machines at the Windemere Hotel consist of three units, two of 50 K. W. each, and one of 30 K. W., and they are specially adapted for isolated plants on account of the small floor space they require. The dynamo room is only 30 x 14 feet in size, which, however, is ample for the three Waddell-Entz dynamos and McEwen engines which it contains, as each of the large units occupies a floor space of but 70 square feet over all, and the smaller one 54 square feet, which leaves ample passageway between the machines. The dynamos add only a small amount to the space needed for the engines. The armatures, owing to their position, are well ventilated, and run with a very small rise in temperature, and the operation of the plant has given entire satisfaction to the proprietors, who speak in the highest terms of its performance.

The Waddell-Entz Company, which has its factories at Bridgeport, Conn., is now making a specialty of these low speed direct connected dynamos, motors and storage batteries, and its work in the electric railway field includes the Harlem division of the Second Avenue Railway, N. Y., for which it has erected a complete storage battery plant, including generators, car motors, batteries, electric cranes, lighting, etc.

The officers of the company are Percival Knauth, president; M. Waddell, vice-president and general manager; J. A. Machado, secretary; A. A. Whitman, treasurer; J. B. Entz, general superintendent.

The International Electrical Congress.

The International Electrical Congress, which meets in Chicago August 21, is expected to include the most representative list of electrical men who have ever met in consultation, and every effort is being made to secure as large an attendance as possible. To this end Prof. Elisha Gray, president of the Advisory Committee, has appointed Mr. C. O. Baker as chairman of a transportation committee, and it is expected that a large Congress Special will run. A circular containing information for the benefit of Eastern members is in preparation by Mr. Baker, and will be shortly issued from his headquarters at 136 Liberty street, New York, where the National Electric Light Association has placed its offices and facilities at his disposal.

We are informed by the chairman of the Committee on Invitations that over 950 special invitations have been issued to date, besides a number of special invitations to electrical societies in different countries, and the replies received indicate that the gathering will be a notable one, especially in the number and distinction of the foreign representatives.

It is expected that the attendance will number upward of 500, and the indications point to a most interesting nad brilliant event.

Practical Aspects of Low Frequency Electrical Resonance—III.*

BY M. I. PUPIN, PH.D.

7. EFFECT OF IRON ON THE RESONANT RISE OF POTENTIAL.

I have already remarked that iron behaves in a peculiar manner when under the inductive action of a resonant flow of electricity. Allow me to call your attention to the diagram of Fig. 9. This curve was obtained with the machine and the circuits which are given in Fig. 7, except that the inertia coil D had smaller self-induction. Keeping the speed of the machine and the self-induction of the circuits constant, the difference of potential in the condenser was varied by varying gradually the capacity of the condenser. Taking then the capacities for abscissæ and the corresponding voltmeter readings for ordinates, the curve in Fig. 9 was obtained. As you see, the curve has two maxima. The corresponding capacities are to each other as 1 : 9. Hence the impressed E. M. F. can be represented by

$$E = E_1 \sin pt + E_3 \sin 3\,pt.$$

A comparison of the smaller maximum to the larger shows that E_3, the amplitude of the upper harmonic, is very small in comparison to E_1, the amplitude of the fundamental. This is surprising, because from the construction of the alternator one would expect a much stronger deviation of the impressed E. M. F. curve from the simple harmonic.

A similar *harmonic analysis* of the impressed E. M. F. obtained by means of the electro-dynamic interruptor gave curves I, II and III, Fig. 10. Curve I was obtained by inserting a certain capacity in shunt with the primary coil, and then varying the capacity in the secondary and recording the corresponding voltmeter reading. Capacity was measured off as abscissa and the corresponding voltmeter reading as ordinate. Curves II and III were obtained in the same way but with different capacities in the primary circuit. The impressed E. M. F. in each case can be represented by the following complex harmonic:

$$E = E_1, pt + E_3\ in\ 3\,pt + E_5 \sin_5 pt.$$

But the amplitudes, E_1, E_3 and E_5, are different in each case. You see, therefore, that this method of harmonic analysis by the resonant rise of potential is very sensitive in detecting upper harmonies. Hence the natural conclusion that curve Fig. 9 indicates no strongly developed harmonics, simply because they were not present. Yet it is very difficult to suppose that my alternator generates practically a simple harmonic E. M. F. when one considers the shape of its armature core.† This point evidently deserved additional investigation.

I inserted a few iron wires into the inertia coil D, Fig. 7, and found that the upper harmonic, weak as it was, disappeared entirely. The iron wires became hot in a very short time. I suspected that iron when subjected to strong magnetization wipes out the upper harmonics in a resonant circuit. With the electro-dynamic interruptor the magnetization of the iron cores is very weak, hence the persistence of upper harmonics. This suspicion was verified in subsequent experiments.

When the inertia coil D was packed with iron wire then the resonant rise was very much diminished, as is evident from the curve in diagram Fig. 11.

Various considerations led me to the conclusion that Foucault current and hysteresis losses were not the only causes of this remarkable diminution of the resonant rise due to the presence of iron. I will mention one only. In one of my experiments I used the primary coil of a small closed magnet circuit transformer for the inertia coil and found that as far as I could detect with my apparatus no resonant rise could be obtained with 100 volts of impressed E. M. F., no matter how low the frequency was which my machine could produce. About 75 periods per second was the lowest frequency which I employed. If, however, the secondary coil of this transformer was short-circuited then the resonant rise appeared, but not nearly as strong as it ought to have been, even Foucault currents and hysteresis losses taken into account. The self-induction of the primary (with secondary short-circuited) calculated from the capacity which produced resonance was far too high. There were unmistakable evidences in this, and in all my other experiments in which iron was present in the inertia coils, that the lower the frequency the stronger were the resonance effects.

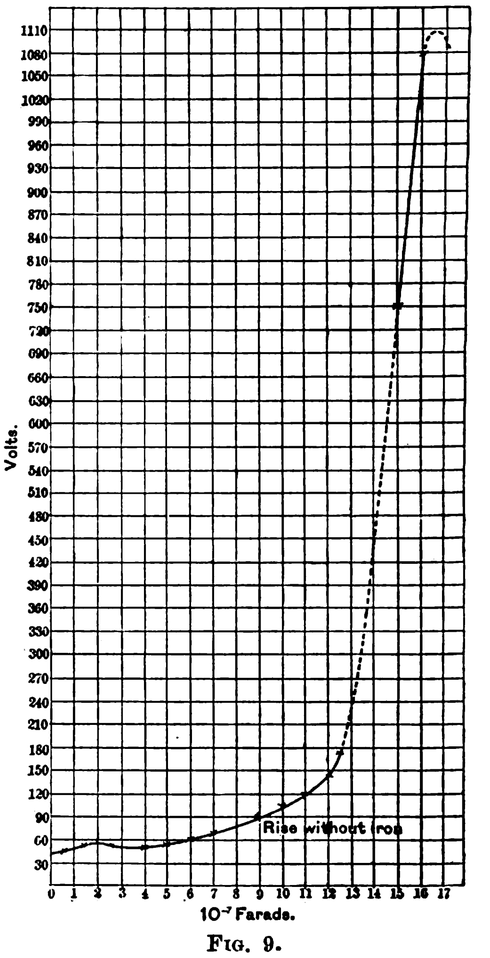


FIG. 9.

When an alternator giving 125 periods per second was substituted for the alternator in Fig. 7 (which gave about 350 to 375 periods per second), then the resonant rise with iron wire core in the inertia coil D was one-half of that when no core was used, the impressed E. M. F. being 45 volts. If, however, the impressed E.M.F. was raised, then this difference in the two cases continually diminished. When the impressed E. M. F. was 200 volts, then the resonant rise with iron was more than without it.

There seems to be in the iron a certain reluctance against getting into full swing when under the inductive action of resonant current. The higher the impressed E. M. F. and the lower the frequency the easier it is to overcome this reluctance. When the iron has once been set into full swing, then it is possible by careful manipulation to lower the impressed E. M. F. and increase the frequency without getting the iron out of this swing. In a closed magnetic circuit this reluctance seems to be exceedingly great.

With a frequency of 50 periods per second the resonant rise with iron was invariably more than without it. Two features in the peculiar behavior of iron were brought out by the resonance experiments with this low frequency machine. These two features, I venture to suggest, deserve more than ordinary attention.

---

* A lecture delivered at the Tenth General Meeting of the American Institute of Electrical Engineers, Columbia College, New York.

† The armature core was a Crocker-Wheeler tooth armature.

The first peculiar feature is exhibited in the two curves, Figure 12. Curve II was obtained when the whole iron wire core (about 500 wires each 40 cm. long and 1 mm. in diameter) was inserted into the inertia coil. The other curve was obtained when only one-half of the core was employed. The frequency was maintained constant. From the critical capacity in the two cases it is evident that there was much less difference in the coefficient of self-induction in the two cases than one might expect from the difference in the quantities of iron, that is, if we suppose that in this case also the natural period of the circuit is independent of the frictional resistances due to magnetic hysteresis. But even if we drop this hypothesis, still the small difference in the capacity in the two cases appears as puzzling as ever. We have resonance in this case also as in any other case, but it is evident that the conditions of resonance are not determined by self-induction and capacity alone. The question arises then, what does resonance mean in this case? Well, it means the largest current and the highest rise of potential, but this maximum potential and current are not necessarily accompanied by zero difference in phase nor by neutralization of self-induction with capacity.[*] The practical bearing of this result needs no further comment.[†]

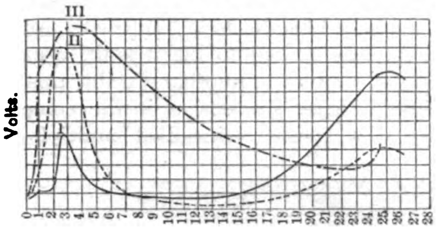

FIG. 10.

There is another point to which I wish to call your attention in connection with curves I and II of Fig. 12. It is this: Although curve II was obtained with twice the quantity of iron, and therefore with at least twice the losses due to Foucault currents and hysteresis (since the magnetizing current which circulated in the inertia coil with resonance corresponding to curve II was considerably larger than that corresponding to resonance of curve I), yet the rise of potential in curve II was larger than that in curve I. I do not wish to take up too much of your time in showing you all of the difficulties which one encounters in endeavoring to explain these matters satisfactorily. Suffice it to point out merely that these difficulties do exist, and that they deserve our most careful attention.

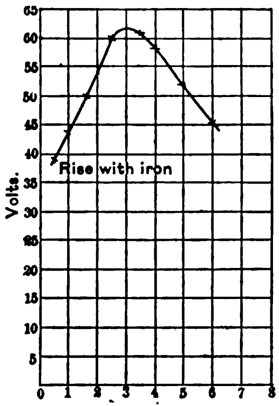

FIG. 11.

Before making the next step in my discourse I wish to remark that a circuit consisting of the armature of an alternator, a large inertia coil without iron, and a condenser, all in series, does not exhibit any of the peculiarities just mentioned, at any rate not to any considerable extent. Such a circuit can be tuned and a high resonant rise of potential can be thus produced, provided, of course, that this rise of potential is not accompanied by so heavy a current as to produce a serious armature reaction. Foucault current and hysteresis losses in the armature iron cannot, of course, influence this resonance, since they are taken care of by the motor which rotates the armature.

The second peculiar feature in the behavior of iron when it is under the inductive action of the resonant current of an inertia coil will be exhibited to you in the following experiment; the arrangement is just the same as that given in the diagram of Fig. 7, with the following exceptions: This alternating current ammeter is in the resonant circuit. The motion of its index, which I hope can be seen all over the room, will indicate to you the progress of tuning. I watch it on this side by means of a multicellular voltmeter which is denoted by F in the diagram of Fig. 7. This four-pole 1 H. P. alternator which Dr. Laudy, of Columbia College, kindly lent me, takes the place of the 16-pole alternator. Inertia coil, alternator and condenser are in the series. The driving motor can easily take care of 2 H. P., so that the speed will remain constant during all variations of the load, since, as you will presently see, the load will never be over 150 watts. The condenser has now 16 M. F. capacity plugged in. The frequency is about 50 periods per second. The impressed E. M. F. is 45 volts. To bring the circuit in resonance with the impressed E. M. F. it is necessary to insert iron wires into the inertia coil. I insert now about 400 wires. It is, as I can see from the voltmeter reading, considerably too much, and therefore there is no resonance, as you can see from the ammeter. I take the iron wire bundle and raise it slowly, and now I can feel by the pull on the bundle and also by the voltmeter reading that I have reached the point of resonance. You can see it by the ammeter deflection. The ammeter indicates 1 ampere; in reality it is about 2 amperes. [This instrument is a lecture room model and its reading must be multiplied by a large correction factor.] Now I lower slowly the iron wire bundle again; the resonance persists. I have reached now the same position from which I started and when there was hardly any resonance effect. But as you see, this time the resonance effect is very strong. But it is a resonance which resembles very much a supersaturated zinc sulphate solution. A very small crystal thrown into such a solution will cause a sudden precipitation of innumerable small crystals. So it is with this resonance. If I now bring a single iron wire near the bundle, its mere approach upsets the resonance almost completely, as you see from the sudden drop of the ammeter needle. But if I add this wire whose mere approach upsets the resonance almost completely, and even five other wires, to the bundle, and then by gently raising it start the resonant flow, I can then lower it again without disturbing resonance, as you see it from the deflection of the needle.

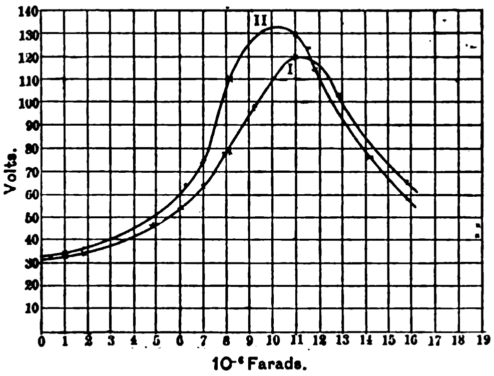

FIG. 12.

I shall vary now the capacity by taking out carefully one plug after the other. But I must take out these plugs without causing a spark. Here is one plug out, and here another, and four more. I have reduced the capacity by 1 M. F. or nearly 7 per cent. of the total capacity. There is hardly any change in the resonance effect, as you see from the ammeter needle. Now I shall carefully put back the plugs, and even more than I have taken out, but carefully avoid sparking. As you see, resonance still persists without any apparent change. Now I take out one plug and vary the capacity by only 0.1 M. F., but I take it out in such a way as to produce a strong spark by the renewal of the plug. The experiment does not succeed. But here it succeeds at the removal of a 0.3 M. F. plug. The collapse of the resonance effect is, as you see, almost complete. Generally I succeed with even less than a 0.1 M. F. plug.

The same peculiarities appear also at higher frequencies, but they are not nearly as clearly defined at frequencies over 100 as they are at those of less than 50 periods per second. They are certainly not due to any change in the speed of the machine produced by the variation of the load due to the rise of the resonant current. Nor is it probable that they are due to armature reactions. This last point, however, deserves a closer examination than I have been able to give it as yet.

One more point I feel that I ought to mention before I end my discourse. It is a point which I think may have some practical importance sooner or later. When a large inertia coil without iron is joined in series with the armature of the alternator and also with a condenser and then the circuit is tuned, so as to analyze harmonically the shape of the impressed E. M. F. curve, I find in all the machines that I have tried so far that this curve is almost perfectly free from upper harmonics, even with frequencies of 50 periods per second. If, however, the armature is closed by the primary of a transformer, then upper harmonics will appear, as for instance in the arrangement in Fig. 7. I do not think that these upper harmonics are entirely due to the variation of the permeability of the transformer core during each complete cycle, as has been suggested by very competent authority.[*] A different interpretation of the phenomenon is possible. My experience in this matter favors the view that the upper harmonics are due to the interference between the electromotive forces generated in the alternator and the transformer. I prefer, however, to devote more time to the examination of this exceedingly important subject before venturing to discuss the validity of this possible new interpretation.

Allow me now to sum up briefly the main points of this discourse.

The practical bearing of "Low Frequency Electrical Resonance" in so far as I have worked out the subject seems to rest on the following characteristic features:

It brings out very prominently the purely mechanical character of the phenomena of electricity, and it does that, not by referring to carefully prepared delicate experiments of a skilled physicist, but by referring to phenomena which every electrical engineer can observe every day in the testing room, telegraph and telephone station, and in central stations for power and lighting. A full appreciation of this purely mechanical character of the phenomena of electricity is of the greatest practical importance, for we must remember that the founder of this mechanical view, the immortal Maxwell, in opening this new view of electrical phenomena contributed to the advance of this science as much as, if not more than, any other investigator of this century.

---

[*] Professor Duncan informed me yesterday that he arrived at this conclusion in a somewhat different way. See paper already referred to.

[†] Especially when Dr. Duncan's more definite conclusions on this point are taken into account.

[*] See Professor Duncan's paper already cited; also H. A. Rowland—"Notes on the Theory of the Transformer," *Phil. Mag.*, July, 1892.

It offers a new, simple and exceedingly convenient method of transforming electrical energy from low to high potential.

It enables us to observe very accurately the behavior of dielectrics and of iron when under the inductive action of resonant currents, and thus to determine the exact limits within which condensers can be employed in the solution of electrical engineering problems.

It offers a new and exceedingly simple method (the method of harmonic analysis mentioned above) of studying the working of alternating current machinery under various conditions of load.

It points out a new and apparently very promising direction in which the difficult but exceedingly important study of the magnetic properties of iron can be pushed ahead.

In closing my remarks I wish to thank my pupil, Mr. Milton C. Canfield, for the very efficient assistance he has given me in the preparation of this lecture.

(Concluded.)

World's Fair News.

Among the exhibits made by foreign firms none will be found more interesting than that made by Felton & Guilleaume, of Carlswerk, Mulheim-on-Rhine, Germany. The exhibit is in the section devoted to the German Government, which is situated in the northeast corner of the Electricity Building. The background of the space is occupied by a magnificent glass fronted show-case, which is divided into eleven compartments, containing specimens of some typical class of goods manufactured by the firm. The following are among the goods exhibited:

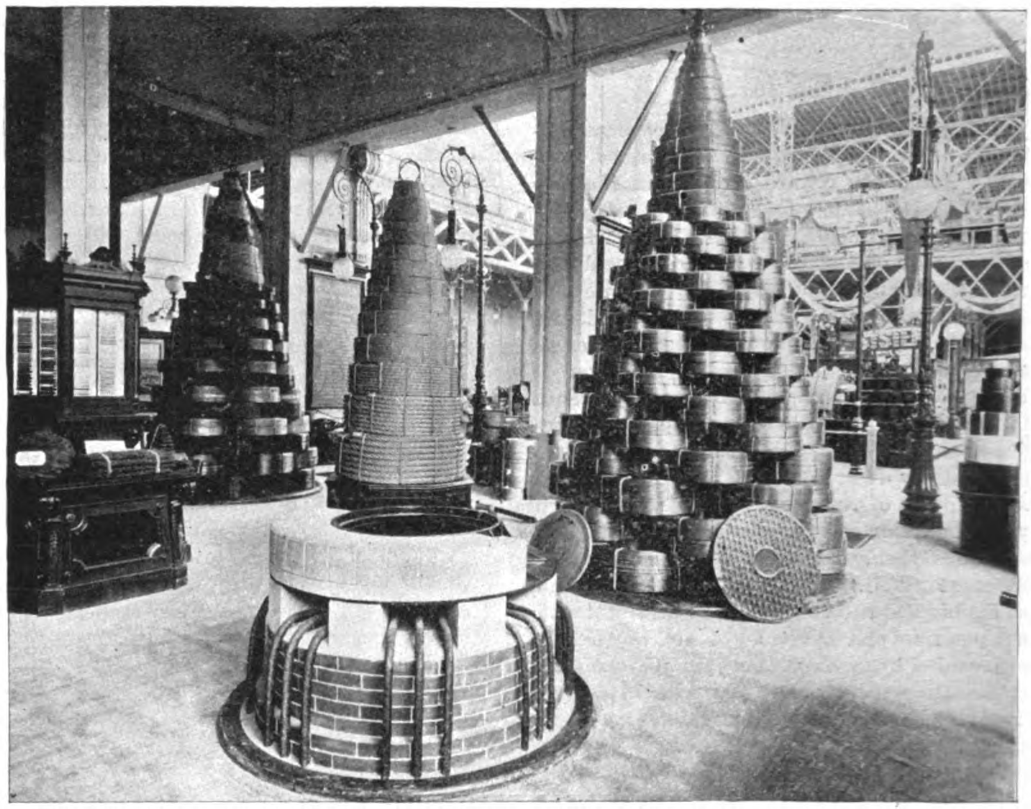
Telegraph cables covered or insulated with indiarubber, gutta percha, impregnated fibre and paper and air space, the latter of which is a valuable patent of Felton & Guilleaume. Torpedo cables are also exhibited in great variety, as are also telephone cables. Electric light cables in various insulations are represented by various specimens, among which are some very interesting cables made for transmitting high frequency alternating currents. Besides the specimens represented in the cases, different specimens of wire and cable have been arranged in the form of pyramids in the foreground, as illustrated in Fig. 1. Some idea of the magnitude of the exhibit may be found if it is borne in mind that the base of each pyramid is 25 feet in diameter and weighs over ten tons. The firm of Felton & Guilleaume are represented in the United States by J. H. Bunnell & Company of New York.

The details of the tests which are to be made on the electrical apparatus by the Committee on Awards was finally adopted last week. The tests are to be of three kinds, and are designated as tests A, B and C. They are as follows:

"A" tests: Not less than one or more than three complete tests are to be made with each apparatus to ascertain the economy in the use of steam and the relation of the indicated H. P. to the electrical output; one of such tests to be made with a load corresponding substantially with the maximum efficiency, one near the minimum allowable load, and one near the maximum allowable load.

"B" tests: Partial tests, supplementary to the above, without measuring the water evaporated, but varying the load by gradual increments through the practicable range to be made for comparing the indicated H. P. with the electrical output.

"C" tests: These tests are designed to aid in distributing the energy developed in the engine in excess of that shown by the output in watts, to include friction tests of engine and a determination of the resistance caused by exciting the field with the main circuit open; they include also tests of electrical resistance, heating of armature, field, etc.



Felton & Guilleaume's World's Fair Exhibit.

Arrangements have been made so that all apparatus to be tested shall be operated at least four hours with a load of not less than three-fifths of its full capacity before the committee take charge of it to test. The first complete or "A" test is then to be made, to be followed by the minimum "A" test, and that to be followed by the maximum "A" test. In case the committee find that they cannot complete a test at one time, the rule as to operating the dynamos for four hours before each test shall be followed the same as in the initial trial. The same preliminary is to be carried out in the tests designated B and C.

The following additional names have been added to the committee since the last report:

Ralph W. Pope, secretary of the American Institute of Electrical Engineers.

Dugald C. Jackson, Professor of Electrical Engineering, University of Wisconsin.

William Schraeder, Professor of Physics and Engineering, University of Missouri.

A. B. Ayres, Tulane University, Louisiana.

S. R. Tompkins, Professor of Electrical Engineering and Physics, Clemson College, South Carolina.

The question of signs seems to have taken possession of the exhibitors occupying the Electricity Building. Since the Westinghouse Company led off with the big Columbus sign on the south wall, the other companies have realized the value of advertising space, and have therefore applied their names and business to nearly every portion of unoccupied space around the building. The Fort Wayne Company have started the painters at work on the north wall of the Electricity *Building*, and it is expected that their name will be indelibly stamped upon the public mind, although the sign occupies a position at the opposite end of the building from their exhibit. The General Electric have also been infused with the sign idea. Last week two signs, 10 by 80 feet, bearing the company's name in large gilded letters were hung from the east and west balconies.

The Western Electric Company are continually adding novelties to their exhibit. The last is a horseshoe magnet, tightly secured to the floor, the pole pieces projecting upwards. An armature with a polished handle is laid across the top, and the public is invited to lift it as the current is turned on and off. Another exhibit that is attracting its share of attention in the company's display is a recently installed multiple drill press. This machine consists of twenty-four adjustable spindles so arranged that twenty-four different and distinct holes can be bored at one operation. The machine as exhibited is used in turning out souvenir blocks in which all of the different holes are drilled with the company's name on one side and "Drilled at One Operation" on the reverse, all of the work being done at the same instant.

On invitation of Helen Louise Johnson, editor of *Table Talk*, and by the courtesy of the Ansonia Electric Company, the Board of Lady Managers assembled in the north gallery of the Electricity Building last Wednesday, and listened to a very interesting lecture, with practical illustrations, on cooking by electricity. After the lecture a light lunch which was cooked by electricity was served.

A proposition is reported having in view the closing of the greater part of the Fair buildings in the evening. Director-General Davis has sent a communication to the Council of Administration recommending that hereafter all the Exposition buildings except the Electrical, Machinery and one other be closed every night. The Director-General's letter means that the Electricity Building shall be the only exhibit building fully open every night; that Machinery Hall shall be open only so far as relates to the operation of the machinery, and that the third building to which night visitors will be admitted shall be changed from night to night.

Electrophone Service.

The electrophone is practically the telephone modified in such a manner as to serve the purpose of transmitting sound from public buildings, such as concert halls, theatres, churches and lecture rooms, to certain centres for redistribution, thence to receiving points by conductors radiating from these centres or exchanges. The scheme was originally tested in London, but Paris was the first city to put it into practical use. It is now more than four years ago that the "Theatrephone"—to give it the French title—was started by a Parisian syndicate, formed for that purpose, and in that short period it has achieved a distinct success. At the present time the list of subscribers numbers over 1,500, with a rapid and continuous increase, and their installation is connected with all the principal theatres in the city. During the Electrical Exhibition at the Crystal Palace, the idea was given a trial which extended over five months, several of the London and one or two provincial theatres being included in the experiments. A charge of sixpence was made to the public, and during the period named 57,922 persons passed the turnstile of the hearing room, realizing a total receipt of £1,448. Still it was the marked success attained by the Parisian company as a permanent going concern that really suggested the formation of a syndicate for the purpose of establishing the system in London, though on a much more complete and comprehensive basis ; for, while the object of the French company seems, at any rate at present, limited to catering for the amusement of the public by supplying them with *petits morceaux* from their favorite theatres, the range of the English company is intended to be much greater. The initial part of their programme is, however, identical with that of the French company, viz., to enable the public, by payment of a small fee, to hear a portion of the entertainment proceeding at one or other of the London theatres, and this object is attained in the following manner. Specially constructed transmitters are placed on the stage of the theatre, just in front of the floats (or footlights), from whence the sound is conveyed over the wires of the National Telephone Company to the electrophone exchanges for redistribution to private subscribers, and a system of automatic boxes, which it is proposed to fit up in clubs, restaurants, railway stations, hotels, and similar places of public resort. The insertion of a coin in the box entitles one to a hearing of from five to ten minutes of the entertainment that may be on the circuit at the time. At the expiration of the fixed period automatic disconnection takes place. These boxes are controlled from the exchanges, and when an *entr'acte* occurs at one theatre they are all connected with another. The company, says *Industries and Iron*, has already arranged with the leading London theatres, and indeed connections are already completed with the following: Criterion, Gaiety, Comedy, Lyric, Prince of Wales', Shaftesbury, Trafalgar Square, Empire, Alhambra, Olympic, Grand and Royal Aquarium, and a room has been fitted up at the Earl's Court Exhibition where selections from the entertainments at the above houses can be heard during the evening. The result has been entirely satisfactory, music—either choral or solo, vocal or instrumental—or dialogue being transmitted with absolute clearness, a result which is attained by the use of a double metallic circuit, so that each listener hears on four wires.

The amusement portion of the scheme is not confined to London theatres, etc., only, for the provincial theatres will also be included. The latter, however, will not apply to the automatic boxes, but will only be available to private house subscribers to the National Telephone who, by making special arrangements with the Electrophone Company, can enjoy the music or dialogue of either London or provincial theatres in the privacy of their own residences.

In addition to places of amusement, it is anticipated that connections will be established at the Law Courts, and it is hoped that it may, later, be possible to obtain the same privileges in the House of Commons. Several members of Parliament are strongly in favor of the idea. Of course, this part of the scheme is, as yet, only a possibility, but it must be said that the electrophone people seem very hopeful that they will ultimately be able to announce it as an accomplished fact. One thing in their favor is that the transmitters are very small, and could be fitted so as to be invisible to any ordinary observer.

The whole of the rights for England of the French patents have been acquired by the Electrophone Company, but important modifications and improvements have been made in the system of working, while the automatic boxes are the work of an English inventor, and are held by the company under British patent. In addition to the work already designated the company contemplate attaching an intelligence bureau to their central exchange for the convenience of their customers, where commissions of any kind will be carried out for subscribers for a small fee. The bureau will be made as complete as possible in its operations, the idea being to provide means of saving time to clients. Thus there will be a shorthand writer and typewriter, who will be at the disposal of any registered subscriber who may wish to drop in and dictate letters, etc., while a registered subscriber wishing any small commission carried out, or any inquiries instituted, has only to telephone to the bureau to insure his desires being executed. The whole of the installation work of the company is carried out by the National Telephone Company, who have agreed not to carry any similar service from places of amusement or public resort for any person or persons other than the Electrophone Company for a certain period of years. In conclusion, it may be mentioned that the Electrophone Company are prepared to supply their system in connection with theatres and churches to the principal London hospitals free of any charge beyond that of actual cost of installation. This would be a source of pleasure and comfort to the thousands of sufferers who, during each year, are treated in these institutions.

The Hodgkins Fund Prizes.

In October, 1889, Thomas George Hodgkins, Esq., of Setauket, New York, made a donation to the Smithsonian Institution, the income from a part of which was to be devoted "to the increase and diffusion of more exact knowledge in regard to the nature and properties of atmospheric air in connection with the welfare of man."

With the intent of furthering the donor's wishes, the Smithsonian Institution now announces the following prizes to be awarded on or after July 1, 1894, should satisfactory papers be offered in competition :

1. A prize of $10,000 for a treatise embodying some new and important discovery in regard to the nature or properties of atmospheric air. These properties may be considered in their bearing upon any or all of the sciences—*e. g.*, not only in regard to meteorology, but in connection with hygiene, or with any department whatever of biological or physical knowledge.

2. A prize of $2,000 for the most satisfactory essay upon—

(*A*) The known properties of atmospheric air considered in their relationships to research in every department of natural science, and the importance of a study of the atmosphere considered in view of these relationships.

(*B*) The proper direction of future research in connection with the imperfections of our knowledge of atmospheric air, and of the connections of that knowledge with other sciences.

The essay, as a whole, should tend to indicate the path best calculated to lead to worthy results in connection with the future administration of the Hodgkins foundation.

3. A prize of $1,000 for the best popular treatise upon atmospheric air, its properties and relationships (including those to hygiene, physical and mental). This essay need not exceed 20,000 words in length; it should be written in simple language and be suitable for publication for popular instruction.

4. A medal will be established, under the name of the Hodgkins Medal of the Smithsonian Institution, which will be awarded annually or biennally for important contributions to our knowledge of the nature and properties of atmospheric air, or for practical applications of our existing knowledge of them to the welfare of mankind. This medal will be of gold, and will be accompanied by a duplicate impression in silver or bronze.

The treatise may be written in English, French, German or Italian, and should be sent to the Secretary of the Smithsonian Institution, Washington, before July 1, 1894, except those in competition for the first prize, the sending of which may be delayed until December 31, 1894.

If no disposition be made of the first prize at the time now announced, the Institution may continue it until a later day, should it be made evident that important investigations relative to its object are in progress, the results of which it is intended to offer in competition for the prize. The Smithsonian Institution reserves the right to limit or modify the conditions for this prize after December 1, 1894, should it be found necessary. Should any of the minor prizes not be awarded to papers sent in before July 1, 1894, the said prizes will be withdrawn from competition.

A Great Electric Scheme.

A party of Eastern capitalists, said to have some connection with the Santa Fe Railroad system, has been visiting the Grand Canyon of the Colorado River for the purpose of investigating the feasibility of laying an electric cable 500 miles in length along the river with which to drive small steamers up through the Black Canyon and other scenic points, where the cliffs, over a mile in height, overhang the stream. Power is to be generated by water-wheels driven by the current of the river itself, or wherever feasible the water will be diverted into canals cut in solid granite walls and dropped into the river again.

A copper wire cable will be suspended over the centre of the river, which is for the most part about 300 feet in width, and electric power will be conveyed to small steamers similar to the manner of running electric railways. The idea is that this will become the most popular route for tourist travel, in comparison to which the Yosemite will sink into insignificance. Another and main feature of the scheme is to convey surplus power down the river, where it will be used for pumping the water of the river to a height of from fifteen to twenty feet upon mesa lands for irrigation, converting an area larger than Massachusetts, now a desert, into a garden patch, where land is now valueless, and where fruits ripen in April, May and June, commanding the highest market prices.

It is announced that the New York, New Haven and Hartford Railroad Company has decided to follow the example of the Pennsylvania Railroad, and erect along its entire system a line of long distance telephones with which to transact its business between important points. It is figured that there will be big economies in substituting the telephone for the telegraph.

ELECTRICITY.

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.

BOSTON:
W. S. KEY, - Room 75, 320 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

" Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

INDEX TO VOL. IV.—The Index to Vol. IV of "Electricity" is now ready, and will be mailed to any address, upon request, from the main office, 6 Park Place, New York, or from our branch offices in Boston and Chicago.

The Storage Battery Situation.

The unfortunate litigation in which a large number of electrical patents have been involved has been the means of retarding the development of the art in many directions, and in no instance is this fact more apparent than in the case of storage batteries. A glance at the progress of this industry at home and abroad will amply attest this fact, and it is only necessary to examine the course pursued by the holders of the broadest patent in this country to explain the fact that in the manufacture and use of accumulators America is at least five years behind Europe.

It is perhaps not equally apparent why those having this business largely under their control have made no effort to keep abreast of the times by perfecting and introducing an article for which so great a demand exists, but it must be remembered that this company is controlled by the Trust, which evidently considers this branch as an interference with its other business, and only holds these patents as a means of obstructing any advances in this line.

It is well known that the company claiming to legally manufacture the only practical storage battery has never produced anything more substantial than a laboratory toy totally unfit for any kind of continuous or severe service, and has taken every advantage of the law to suppress competition. This of course is to be expected, as it is but natural for a company to make its patent claims as broad as possible; nor could any objection be urged against it except for the fact that, like the dog in the manger, it has refused to do anything itself and has prevented, as far as possible, anybody else from making any progress. The attitude assumed by this company is an acknowledged policy of obstruction which would place an efficient battery of this type for central station or railway work out of reach as long as this patent exists. The success which has met these efforts is unfortunately too complete, as there is probably not one concern in this country that can supply accumulators which can compare in quality or performance with any of those now in common use in many European stations.

In traction work the same lack of progress in this direction exists, and elsewhere will be found described this company's effort to bulldoze a competitor after its own apparatus had been rejected. As the opposition in this instance have a strong case, it is to be hoped that they will maintain their stand through the courts, and confine the obstructionists to the strict limit of their patents.

……o……

HOLDERS of General Electric shares had one consolation when they saw the price drop to 31¼. There was only $31.25 more to lose on every share they held—unless, as in Richmond Terminal, there was an assessment of $1.50 a share before they could get out clear.

More Lamp Factories Closed.

The advantages gained by the Trust in recent lamp litigation should not be underestimated. While they can not result in any material increase of earnings for the Trust itself within the next three months, they may easily pave the way for a further abuse of the privileges intended to be granted under the United States patent law.

The flat refusal of the New York Edison Company to sell lamps for use on an isolated plant in the Holland House, this city, noted in another column, is a fair example of what may be expected in the future. The equally flat refusal of the proprietors of this building to change their method of lighting, and their purchase of a supply of Westinghouse lamps, is proof of the fact that the purchasing public may be looked to to support independent manufacturers.

While we look for a complete victory for the outside interests at the final hearing in the Oconto case, which is soon to come up, and the early re-opening of the closed lamp factories, this is no time to idly await developments, or to go to sleep.

No opportunity should be lost for striking a blow at the Trust, and ELECTRICITY's only regret is that it is not able to print seven issues a week instead of one issue.

……o……

The Aid of Congress Must be Invoked.

By the time this issue of ELECTRICITY reaches our readers in the West, Congress will have convened in special session, and it should be invoked to lend its aid to secure justice to the entire public in the matter of the supply of electric lights—a public necessity—and to those who have invested their money in good faith in electrical manufactures.

The best interests of the art and of the trade demand that the Electric Trust should be compelled to abandon its illegitimate use of United States patents and to reorganize on an honorable and business-like basis.

If every man in the trade does his full duty in laying this matter before his Representative in Congress, a full and impartial investigation of the methods of the Electric Trust can not be avoided.

Such an investigation would result in the annihilation of the Electric Trust.

ELECTRICITY has on hand a number of copies of the blank forms of petition, printed two weeks ago, which we will be pleased to send free of charge to those who can use them.

The Trust scheme is not yet dead. It has, indeed, been crippled by the mismanagement of its own officials, and is temporarily weakened. But it is even now preparing to again raise its ugly head in defiance of the law, of decency, and of justice to invested capital.

Now is the time to strike—the time for every enemy of monopoly to do his duty.

……o……

THE Electric Trust having sold apparently all its treasury assets, the question arises, What will it sell the next time it needs money in its business? Will it sell its factory machines and office furniture?

The Truth is Coming Out. The developments in General Electric affairs last week were no surprise to those whose acquaintance with T-H. business methods extends back six or eight years.

They were not a surprise to the Wall Street speculators, who have a cruel habit of forming their own judgment of the affairs of a company, regardless of the high standing of the executive heads, and regardless of the number of official misstatements put forth.

If any one was surprised it was those stockholders who have paid no attention to the affairs of the company but have merely relied on the statements put forth by various members of the Board of Directors. And there is a mild suspicion abroad that some of these Directors, upon whose good names the company has lived for a year and a half, were also surprised. The comments of the *Tribune* are noteworthy as leading to this opinion.

It is the honest opinion of ELECTRICITY—and our opinion is reinforced by the judgment of the best-informed men in the business—that the company has from the start been paying money for dividends which never should have left the treasury, and that *a rigid adherence to the spirit of the law would have made the payment of any dividend whatever an impossibility.*

A synopsis of the various reports given out from time to time since the company was founded will appear in due season; if the same methods had been pursued by men of less standing in their respective communities, there would have been talk long before this of vigorous proceedings.

As the case stands to-day, the worst charges made by ELECTRICITY are thoroughly substantiated. Thousands of investors have lost their money in the largest electrical enterprise in America; they have lost it through the basest kind of misrepresentation, and the entire electrical business of the country will be the sufferer for a long time to come. Capital will not be easily found henceforward for any electrical enterprise whatever.

When we went to press last week we scarcely looked for the fulfilment of our prophecies to come so soon. But from the partial report which we have obtained of what took place at the Directors' meeting, referred to elsewhere, there is no reason to doubt that Drexel, Morgan & Company are in actual control of the company, and that a radical change in the management will not long be delayed. There is, further, no reason to doubt that the sub-companies in which the old T.-H. element were largely interested as individuals, have been worked to milk the parent company in a way that was scarcely looked for by the New York members of the Board of Directors. There will be a speedy end to this sort of thing.

The Boston clique, notwithstanding their brilliant record as financiers in New England, have proved themselves but children in Wall Street knowledge, and their usefulness as actual managers is at an end. There can be no doubt in the minds of any student of the situation that it required the strong arm of Mr. Pierpont Morgan himself to save the company from wreck.

Little by little the truth is coming out, and it will yet be plain to the bitterest enemies of ELECTRICITY that we have been too moderate in our criticisms.

That the General Electric Company has reached a turning point there is not a shadow of doubt. The success of the company will now depend on the thoroughness with which the T.-H. element are weeded out, and the liberality of the policy pursued towards their honest competitors in the field.

Until there is some assurance from headquarters that these suggestions will be acted on, there will be no diminution of the odium under which the company is now suffering, no softening of the feeling of bitter hatred which permeates the trade.

······o······

What Does It Mean? In April last the General Electric Company published its first annual statement, making the flat assertion that the net profits for eight months had been upwards of $3,000,000, but withholding all information in regard to volume of business done and running expenses.

And the stock went down.

Some weeks ago there were many rumors afloat that the company was in serious need of funds, and that trouble was near at hand.

The stock went down.

These rumors were officially denied.

The stock still went down.

Then came the sale of New York and other local Edison illuminating companies' stock—a confession that the statements referred to had not been correct. At about this time the vice-president of the company was quoted in an interview as saying that the company "had been" in need of funds, but that the sale of these Edison illuminating companies' stocks would give them plenty of cash for a long time to come. Then the vice-president denied having made such an admission. Afterwards, we are told, he denied his denial.

The stock continued to go down.

Then came the official statement, which was not denied, that the proceeds of the sale of these gilt-edged treasury assets would pay all maturing obligations of the company then in sight.

And the stock again went down.

At this point the Wall Street bears asserted that these treasury assets had already been used as collateral for loans, and that the margin left to go into the Trust's treasury was not large; and ELECTRICITY asserted that when a man pawns his watch or his best suit of clothes he must be in need of funds.

And the stock went down.

Last week the Directors met "to consider new contracts," as it was announced.

And again the stock went down.

After the Directors' meeting it was officially announced that it had been decided to sell $4,000,000 of treasury assets, which would pay off all the floating debt, and that 70 per cent. of the $4,000,000 had already been pledged.

And the stock went down.

The next morning it was rumored that Drexel, Morgan & Company had secured a controlling interest in the company.

And the stock went up.

······o······

The Art of Drawing Specifications. The manner in which the agents of the General Electric Company endeavored to make a sure thing of the contract for installing the proposed plant at the Joliet Penitentiary, as related last week, will surprise no one familiar with the methods of the Trust. The drawing of specifications is a fine art, and no one understands it better than the General Electric Company. It is gratifying to know that the plan has not worked smoothly at Joliet, and that before the plant is installed there will be a square deal.

That crookedness existed, and that crookedness was relied on to milk the State Treasury of $15,000 to $20,000 there can be little doubt.

To the Chicago *Tribune* is largely due the credit for frustrating the scheme before it was fully developed.

The manufacturer, whether of dynamos, engines or boilers, who becomes a party to any scheme whereby other manufacturers are practically barred from competition for a contract of this nature, publishes to the world the fact that he is afraid of competition, and the only inference is that he is *particeps criminis* in an intended robbery; either his apparatus is not up to the standard or he hopes to get more than the market price by a "divide" with the person authorized to make the purchase.

It looks at this distance as though both the latter were features in the Joliet affair.

······o······

Arc Lamp Specifications. For years the agents of the Thomson-Houston Company, and lately of the General Electric Company, have given special attention to the drawing of specifications for plants upon which they were to bid and upon which they hoped to be the only *actual bidders.* They have never hesitated to adopt whatever means were necessary to bring the engineer around to their views, and in a great many cases they have been successful.

In the matter of arc lighting they have, on account of their ownership of certain patents on double carbon arc lamps, been industrious in their efforts to convince the public that the double-carbon lamp was the only practical all-night lamp, and they have been too successful in this regard. Whenever the opportunity presents itself, they get a clause worked in to the specifications that bids will not be accepted on single-carbon lamps.

This is a radical injustice, and it is time the public were made aware of the fact and of the reasons for the particular solicitude of the Trust lest single-carbon lamps be admitted to the competition.

The fact is that there has been material progress in the making of arc lamps in the past few years, and there are now single-carbon arc lamps on the market which are guaranteed by responsible manufacturers for all-night service, and in many places throughout the country they are in use and giving perfect satisfaction.

And moreover the single-carbon lamps have a decided advantage in the fact that they are simpler in construction, more easily attended to, and less liable to get out of order.

Purchasers of electrical apparatus, whether individuals or corporations, should see to it that the field is left open for free competition. In no other way can they be sure of getting good value for their money.

……

We take pleasure in assuring the Electric Storage Battery Company of Philadelphia that Electricity is with them. We believe they have a good battery. And moreover, we wish to emphasize the fact that the Brush patent, which has been from the beginning in the hands of people who cannot make a good storage battery, has been used long enough as a club to knock in the head all progress in that branch of the art.

……

While the New York *Sun* is recognized everywhere as the brainiest newspaper in America, there has always been a strange fatality attending its prophecies, showing that a man may be a good scribe and at the same time a poor prophet. This has been especially marked in matters of finance and politics. As an example, within forty-eight hours after the *Sun* proclaimed General Electric a good buy at 45 or thereabouts the stock dropped to 33.

……

The Brooklyn City Railroad, which has had about 600 T.-H. car equipments in use for the past year, has used better judgment in placing its last order for 100 motors. Fifty of them will be of the Curtis Electric Company's make and fifty of the Westinghouse type.

A Remarkable Statement.

How the General Electric Company Tried to Silence Criticism.

(*From the Brooklyn Citizen.*)

"In the vicinity of eighty people who had ventured to criticise the conduct of the General Electric management were threatened with imprisonment. When the stock was selling out at 75 it was suggested in this column that but for the fact that criticism or adverse comment regarding the policy of the management or the condition of General Electric was almost an indictable offence a few plain remarks might be made."

The outrageous attempt to throttle Electricity made by the Trust is a matter of record. The failure of that attempt is also, we are proud to say, a matter of record.

The day that General Electric securities were listed on the New York Stock Exchange the affairs of that company became of public interest, and were legitimate subjects for newspaper comment.

The desperate effort made by the officials to keep the facts from the public has been one of the chief causes of the loss of confidence by its stockholders.

If the company's affairs had been in a healthy condition the publication of a full and clear statement would have been the natural course to pursue.

When all the vital facts were suppressed—the gross business done and running expenses—it was conclusive proof that they were not fit to publish.

The Trust may threaten eighty people with arrest every day in the year, but Electricity will, as heretofore, publish all the news and draw its own conclusions.

Legal Notes.

The Packard and Buckeye Lamp Factories Closed.

On Friday, July 28, Judge Ricks, of the United States Circuit Court for the Northern District of Ohio, on behalf of the Edison Electric Light Company et al., granted restraining orders against the New York and Ohio Company of Warren, Ohio, and the Buckeye Electric Company of Cleveland.

Judge Grosscup is Needed in New York.

On June 30, as announced in Electricity at the time, Judge Lacombe granted an order restraining the Holland House and others in this city from using Sawyer-Man lamps. Thirty days were granted to provide new lamps. The Holland House has a Westinghouse isolated plant. The proprietors applied to the Edison Company for lamps, but were met with a flat refusal unless they would also use the Edison current.

Finally, a supply of the Westinghouse stopper lamps having been purchased, the hotel was properly lighted without any infringement on the Edison patent.

Suit has been begun in the Circuit Court at Chicago by Campbell, Zell & Company of Baltimore, Md., against the Illinois Electrical Forging Company for $25,000. The action is brought to collect an account of $22.500 for boilers and machinery supplies furnished the defendant company and for damages and costs.

On Thursday last two suits were begun in the United States Circuit Court, New York, by the Edison Electric Illuminating Company, respectively against the Mount Morris Electric Light Company and the United Electric Light and Power Company, for injunctions restraining them from supplying current for incandescent lamps. These suits are the first suits brought on the patent in question against competing central station companies. The hearing will be held before Judge Lacombe on the 2d inst.

Commissioner Seymour of the Patent Office has rendered a decision in the disbarment proceedings of Church & Church against Foster & Freeman, attorneys for the Bell Telephone Company, and William E. Simonds, late Commissioner of Patents. Mr. Seymour finds that Foster & Freeman are not guilty of wrongdoing, as charged. As to ex-Commissioner Simonds, he finds that what he did was within his discretion as Commissioner, and that the taking of the copies of the Drawbaugh application, especially as he had the consent of Secretary Noble to do so, was not, under the rules of the office, a matter of which he could be cognizant. The complaint, therefore, against all of the parties was dismissed.

The Brush Electric Light and Power Company of Niagara Falls has made application to Justice Ward, of the Supreme Court, for an order of voluntary dissolution. The order is desired to enable them put affairs in shape to be sold to the Buffalo and Niagara Falls Electric Light and Power Company.

Death of John Stephenson.

John Stephenson, the pioneer of American street railway car builders, died on Monday, the 31st of July, at his home near New Rochelle, age eighty-four. He was born in County Armagh, Ireland, and came to this country with his parents in 1811.

Flight of Charles C. Lockstaedt.

Charles C. Lockstaedt, who put in a bid for lighting the World's Fair in the name of the South Side Machinery Company and afterwards turned the matter over to the Westinghouse Company, who secured the contract, has fled from Chicago, after having discounted notes for upwards of $50,000 to which he had forged the name of the Westinghouse Company.

General Electric.

Notes and Comments from Various Sources.

The collapse of the General Electric securities discloses a large floating debt on the heels of the declaration of a dividend at the rate of 8 per cent.—*New York Times.*

At a meeting of the Board of Directors of the General Electric Company it was decided to offer to the stockholders securities now in the treasury sufficient to pay the entire floating debt of about $4,000,000. Of the amount necessary to underwrite the above, seventy per cent. has already been subscribed. The dividend will be paid on Tuesday in cash. A circular will be issued early next week offering to the stockholders for every 100 shares of stock $1,500 par value of the securities in the treasury, which are to be sold at a price to net 80 per cent. of their par value.—*Statement of the Board of Directors.*

At the office of the General Electric Company to-day there was a positive refusal to add anything to the brief and indefinite statement made yesterday afternoon concerning the conclusions reached by the Board of Directors. It was requested that the "securities in the treasury" referred to in that statement as to be used for the payment of the entire floating debt of $4,000,000. be specified, but the request was denied.—*Evening Post.*

The inference from the statements made by officials of the General Electric Company for weeks and months was that this concern was placed in an impregnable position when $6,000,000 of the 5 per cent. debentures were floated some time since. The claim now that the insiders took the series at par and have also been heavy losers on the stock does not go far towards restoring confidence.—*World.*

The raid on General Electric was helped, undoubtedly, by liquidation in that stock on the part of tired holders, who are tired not only of the continued decline in the quotations, but also of the mystery that is observed concerning the operations of the company's business.—*Daily America.*

The statement that the company had something to sell looked as though they needed money and were willing to let go their household effects to obtain it. Another criticism was that it looked strange for a company in such a condition to declare with one breath that it needed money and with the next to assert that the dividend, due August 1, of 2 per cent. was waiting in cash to be paid.—*World.*

It would appear from these statements that the worst about General Electric is now known. This may be true as to its future but not as to its past. According to excellent information, the company has not derived the fullest benefits that it might from its dealings with subsidiary corporations.—*New York Sun.*

Within two months it was stated on high authority that the company had cash or quick assets much beyond its present obligations. It is hardly credible that a floating debt of $4,000,000 has been incurred in sixty days.—*Tribune.*

The untoward developments in the financial situation recently, rather than any sense of their duty to their security holders, have finally compelled an acknowledgment by the eminent capitalists referred to of the actual condition and necessities of the General Electric Company.—*Brooklyn Citizen.*

The official announcement that the General Electric Company had a floating debt of $4,000,000, and that it was forced to sell treasury assets in order to meet these obligations, was a most disagreeable surprise. It is only two months ago that an officer of the company stated that the sale of its Edison Electric Illuminating stock furnished money enough to meet all its obligations for some time, and it is within two weeks that the directors declared the usual quarterly dividend of 2 per cent. It is no wonder that the price of the stock fell abruptly.—*Tribune.*

Litigation Invited.

The Consolidated Electric Storage Company Must Prove Its Allegations.

The Electrical Storage Battery Company of Philadelphia, one of the few competitors of the Consolidated Company, has come into violent collision with the latter on the question of patent infringement and has taken steps to bring the question before the courts at once. The Metropolitan Railway Company of Washington recently adopted storage batteries on their road and have been trying a number of different makes of batteries, of which the "Chloride Accumulator" made by the Philadelphia Company proved one of the best.

The Consolidated Company, which under the Brush patents claims everything in this line except the plain Planté plates, notified Mr. Pearson, President of the Metropolitan Railway, in February and again in July, that they were about to proceed against the Philadelphia Company, and warned him against purchasing or using the chloride batteries. The following reply from Mr. Gibbs, of the Philadelphia Company, speaks for itself:

Electrical Storage Battery Company,
Drexel Building,
Philadelphia, Pa., July 27, 1893.

MR. WILLIAM BRACKEN, President Consolidated Electric Storage Co., New York, N. Y.

DEAR SIR: I am favored with copies of your letters of the 27th of February and 24th of July, 1893, to Mr. George W. Pearson, President of the Metropolitan Railway Company of Washington, D. C., wherein you state that the battery manufactured by the Electric Storage Battery Company of Philadelphia is a clear infringement of the Brush patents, and of which "there is no earthly doubt."

There may be no doubt in your mind. This is not surprising, as you seem to be completely ignorant of the state of the art as applied to the manufacture of storage batteries, but you will find the very greatest legal doubt when you come to take the advice of competent lawyers and experts who are familiar with the state of the art and do not rely upon your statements. No competent lawyer or expert can honestly advise you, with a full understanding of our battery and your Brush patents, as construed by the courts, that our battery infringes any claims of your Brush patent.

You show your ignorance of our battery when you say "They cast a lead frame or support around tablets of active material," for we do nothing of the kind. Our tablets are not of active material when the frame is cast around them, and that even you ought to know considering the experience you are supposed to have had with storage batteries. Our active material is formed out of the tablets by electrical disintegration after the tablets are cast and the frame cast around them. Again, the claims of your Brush patent, as construed by the courts, are not for "active material of absorptive substance," but for a "plate or suitable support primarily coated or combined with mechanically applied active material or material adapted to become active," as you no doubt know, and should have said had your desire been to truthfully advise Mr. Pearson instead of to deceive him to our injury.

By what authority do you say our battery infringes the claims of your Brush patent? Surely on the authority of no court, for, you well know that no court has declared our battery to be an infringement, and although we have been, to your knowledge, openly engaged in manufacturing our batteries for some years, you have not, down to this moment, proceeded against us, although threatening to do so for nearly eight months past. You apparently propose to dispose of our battery and business without even resorting to the courts wherein such questions are usually determined.

Undoubtedly this is the safest way for you, considering that our battery is totally unlike any battery yet held to be an infringement of your patents, and that it is a battery 100 per cent. better in every particular than any battery ever manufactured by you or under your patents. It certainly is a great burlesque on your intelligence or the intelligence of your engineers that we are able to manufacture a battery 100 per cent. better than any you ever produced if any features of your patents are employed by us.

Unlike you, we have sufficient confidence in our position to submit the question to the courts empowered to consider and determine such questions, and there we invite you to meet us at once, and unless you do so or discontinue your libelous statements against our battery, we will take such steps as we are advised are open to us to protect our interests.

We are advised by our counsel and experts that our battery does not infringe any of the claims of your patents, and having confidence in their opinion we propose to continue making and selling our battery, and shall protect and save harmless all users of them, not only as against any claim you may make, but against all claims from whatever source.

Now, being advised of our intentions we demand, in view of statements made in your letter to Mr. Pearson, and to other parties, that you proceed at once against us on a bill for infringement, accompanied with motion of injunction, so that the question of our infringement of your patents may be determined; and to that end we advise you, viz.:

We are a New Jersey corporation with a factory at Gloucester in that State where batteries are being manufactured daily, and we will at any time furnish you with one of our batteries, at the usual price, accompanying same with a sworn statement of precisely how they are made, with permission to use the same in any proceedings against us.

We have, to avoid delay, authorized our counsel, Mr. John R. Bennett, Potter Building, New York City, to accept service of papers in our name and to aid you in every way possible to reach the courts at the earliest possible moment, and you can arrange with him, either direct or through your counsel, for one of our batteries and a statement of its construction.

If you have confidence in your position you will, of course, accept our most reasonable proposition to proceed against us at once, and if you do not we hereby notify you that we shall proceed against you to protect our interests, holding you responsible for the damages resulting to our business by the making of statements and the sending out of such unfounded libelous letters as you have sent to Mr. Pearson.

Very truly yours,
W. W. GIBBS, President.

Mr. Gibbs's opinion as regards the non-infringement is supported by Dr. C. F. Chandler, who, in a report on the chloride accumulator, says:

"In conclusion I am therefore of the opinion that your battery does not either in itself, in the process by which it is manufactured, or in its use infringe the claims of the Brush patents.

"I am familiar with all the batteries that have been held to infringe the Brush patents, and in all of them the distinguishing features of the Brush invention as set forth in the above quoted passages of the opinion of the Court of Appeals were clearly present.

"No battery such as yours has been held to be an infringement of the Brush patent, and from my understanding of the opinion of the court of last resort, the Circuit Court of Appeals, such conclusion would be impossible."

The chloride accumulator plates are manufactured in the following manner: Chloride of lead and chloride of zinc mixed in the proper proportions are cast into rectangular tablets which may be then subjected to such treatment as will withdraw the chloride of zinc and at the same time decompose the chloride of lead and thus convert the tablets into plates suitable for use in storage batteries without any further mechanical treatment.

It is customary, however, to first incase the tablets in a frame of metal, which serves to hold them rigidly and protect them from injury in handling. This is accomplished by placing the tablets of chloride of lead and chloride of zinc in a suitable mould and pouring in a melted alloy of lead and antimony, which flows around the tablets, forming a frame in which they are firmly and permanently fixed.

The above constructed plates of chloride of lead and chloride of zinc are not capable of use in a storage battery. They are not capable of serving as oxygen plates as they will not absorb oxygen.

They are not capable of use as hydrogen plates, as not only would their immersion in the dilute sulphuric acid of a storage battery cell result in contaminating the fluid with chloride of zinc, which would be fatal to its proper action as a storage battery fluid, but the effect of hydrogen liberated would, if any action took place, be to form hydrochloric acid with the chlorine of the chloride of lead, which hydrochloric acid would further contaminate the fluid and make it inoperative as a storage battery fluid; moreover, these tablets are non-conductors of electricity.

It is evident, therefore, that the plate of tablets consisting of chloride of lead and chloride of zinc is worthless in its present condition as a storage battery plate, and cannot be used as such. Its chemical composition must first be radically changed in order to fit it for service in a storage battery either as an oxygen or as a hydrogen plate. This chemical change is brought about by means of a bath of chloride of zinc or some equivalent substance in which the plate of tablets is to be immersed in connection with a slab of metallic zinc. This arrangement is in fact a primary battery in which the zinc acts as the positive element while the tablets constitute the negative element.

The chemical action in this combination results in withdrawing the chloride of zinc from the tablets by simple solution in the bath, and the withdrawal of the chlorine of the chloride of lead from the tablets and the fixing it in combination with the zinc with the formation of chloride of zinc.

The chloride tablets in the plates are not in any sense active material, nor are they material capable of becoming active in a secondary battery fluid.

They only constitute material which may be subsequently rendered active by the electrical disintegration which is brought about when they are connected with the zinc plates in the bath of chloride of zinc. When the process of electrical disintegration is complete and we have washed all the chloride of zinc out of the plate, we have a mass of metallic lead which is suitable for immediate use in a storage battery without the tedious forming process of Planté, and without the application of any active material or material about to become active by the processes of Brush or Faure.

Cleveland Likes the Trolley.

The Cleveland City Railway Company has announced that it will abandon cable power on its Payne Avenue line, about three and one-fourth miles in length, and equip it with the trolley this fall. This company is a consolidation of the Cleveland Cable Railway Company and the Woodlawn Avenue and West Side Street Railroad Company. The latter road was equipped early in the spring with the trolley on all its lines but one, which still retains horses, and when the combination was effected it was predicted that the cable would be superceded by the trolley.

Cable traction has not been a signal success here and the trolley has. The cable road was built to float bonds on rather than to earn dividends on its stock, and it has been found that electric traction is cheaper here than cable and less likely to suffer complete paralysis from a broken cable.

It is believed that the Superior Street cable, which is the other branch of the road, will be replaced as soon as practicable by electricity. It is clear that the cable cannot compete with the trolley in Cleveland.

Among the wedding presents of the Duke of York and Princess May was an electric launch from the Royal London Yacht Club.

Boston Notes.

As the topic uppermost in men's minds in Boston the present week has been the General Electric Company's affairs, so it is entitled to first mention in these notes. There is no gainsaying the fact that everybody is becoming interested in the Trust, and as each succeeding day has dawned the interest has increased until just now, when it may be said that matters are at white heat. Slump, slump, slump has been the action of the stock, and these repeated tumbles, helped by the well founded statement that 2,000 employees have been laid off at Lynn, and the removal of the railway department to New York, have caused such universal consternation that everybody feels confident the end is near. When stocks begin to go off 8 and 9 points at a bound as General Electric has done to-day, no wonder men begin to exclaim, "Where are we at?" and "Listen, if you want to hear something drop."

That is a mighty powerful searchlight that has just been finished by the Schuyler Electric Company of Middletown, Conn., if we may believe the newspaper reports which state that, with lens and mirror five feet in diameter, the light shown by this monster will be equal to 375,000,000 candle power. We rather suspect the printer has wrongly added three ciphers, thus making millions when they should have stated 375,000 candle power. A light of the last named power is a good deal of a flame and indicates how useful electricity has become for lighting up the dark corners of the earth.

We have heard of two or three magnificent contracts for lighting plants ready for placing in New England as soon as the commercial and financial outlook improve. For no other reason are they withheld for the present, and this is an indication of the boom that may be expected as soon as the clouds lift, and that they will lift ere long is the sincere wish of everybody engaged in the electrical as in all other businesses.

Col. L. W. Burnham, the genial manager of he Electric Gas Lighting Company of this city, was to have left Boston for a two weeks' sojourn in Chicago in company with his daughter on Wednesday, but owing to a sudden attack of sickness he has been unable to start this week. Col. Burnham is so widely known and universally respected that his innumerable friends all over the country will receive this intelligence with regret.

A gigantic and handsome electric switchboard is in course of construction at the works of the W. S. Hill Electric Company, for the Boston Museum, the popular old family theatre, that is being renovated throughout and equipped with electric lights, fans and other devices.

The great gathering of cyclists and others at Waltham last Monday evening to see the races that were run under the brilliant rays of innumerable electric lights were more than pleased with the entire arrangements. Though several of the crack wheelmen did not materialize, the crowds thoroughly enjoyed themselves, the electric illuminations demonstrating the practicability of having out-door sports and pastimes arranged to take place after darkness has set in with as great assurance of their being successful as on the most brilliant day.

The frequent exceedingly hot days we have had of late have given quite a boom to the fan motor business, so that every local manufacturer of these useful devices has been about cleared out of his stock, hence the factories are kept pretty busy in that particular line. More than one Boston firm has already sold every fan motor equipment it can make up to the end of the season.

The large factory that is being erected in Milford, Mass., for the building and equipping of storage battery electric cars is being pushed by the company, which does not seem at all daunted by the defeat it has sustained recently in the State Legislature. So sanguine is the company that it is a matter of only a few months, or at most a year or two, when the public will insist on storage battery propulsion, that it is determined to be ready for that time, although even now it is doing quite a business in its own special line and has more to come.

General News.

What Is Going on in the Electrical World.

Denver, Col.—Moonlight excursions over the electric lines here are a popular fad this summer.

Gettysburg, Pa.—Notice to vacate the battlefield has been given to the electric railway company that was laying its tracks within the lines of the battle.

Aurora, Neb.—Bonds have been voted by this city to put in an electric light plant in connection with the waterworks. The city will own both the waterworks and the electric light plant.

Norwalk, Ohio.—Work on the Sandusky, Milan & Norwalk Electric road is at a standstill, and the men have been laid off on account of lack of funds caused by the present financial trouble.

Memphis, Tenn.—The great driving-wheel in the electric power house here exploded on Friday last, the flying pieces tearing up the building and instantly killing the engineer, Patrick McDermott.

Smyrna, Mich.—The Spencer Electric Light and Power Company, which recently filed articles at Belding, will put in two large dynamos at Symrna, utilizing the excellent water power at this place.

Flatbush, L. I., N. Y.—The Knickerbocker Electric Light and Power Company has been granted a franchise to "conduct and distribute electricity for lighting, for power or traction within the town of Flatbush."

Woodhaven, L. I.—The Jamaica town board, having rejected the bid of the Suburban Electric Lighting Company to furnish Woodhaven with arc lights at $80 per lamp, this village will remain in its present unlighted condition.

Washington, D. C—Negotiations have been concluded through which the Great Falls Electric Railroad has passed into the possession of a syndicate, the controlling interest being held by Stilson Hutchins and Jacob P. Clark.

St. Louis, Mo.—The East St. Louis Electric Street Railroad Company has increased its capital stock to $500,000 and issued bonds, the proceeds of the sale of which will be used to complete the double track extension to Fireworkstown.

Buenos Ayres, S. A.—Mayor Latrobe, of Baltimore, having heard that Buenos Ayres had an excellent system of electric lighting, wrote to the American consul for information about it, and the consul's reply was that Buenos Ayres is lighted by gas.

Leavenworth, Kan.—The city attorney has been instructed by the city council to institute proceedings in the District Court to compel the dummy line to forfeit its charter. This means that the company will either build an electric road or be deprived of all rights in the city.

Baltimore, Md.—The Southern Electric Company, of Baltimore, has made a voluntary assignment. Failure to collect overdue accounts made it impossible for the company to meet its obligations. The assets of the concern are estimated at $175,000; liabilities, $100,000.

San Francisco.—At the annual meeting of the stockholders of the California Electric Light Company the old board of directors were re-elected. The directors organized and elected the following-named officers: President, John R. Spring; vice-president, George H. Roe; secretary, J. R. Green; treasurer, the Nevada Bank.

Portsmouth, O.—Work on the Portsmouth electric railway was begun on the 20th inst. "amid music and oratory." Speeches were made by George Davis, president of the company; Sam Timmonds, its secretary; Jas. Whiteley, the contractor, and by leading citizens. After the speech-making the band played enlivening airs.

Elmira, N. Y.—At the conclusion of the Knights of Pythias parade here on Wednesday last, Manager Baldwin, of the Elmira and Horseheads Electric Railway, ran a solid train of sixteen cars to Eldridge Park, carrying nearly a thousand people. This is believed to be the greatest train ever run in this country by electric motors.

New York.—On Thursday night last the entire telephone plant at the Eighteenth street branch of the Metropolitan Telegraph and Telephone Company was destroyed by a fire which gutted the building. The plant was valued at $40,000.—The sheriff, on Friday last, sold out the effects of the Electrical Device Company, No. 42 Wall street.

Philadelphia. — President Widener, of the Metropolitan Traction Company, states that the business of the Catharine and Bainbridge streets road gives an example of the success of the trolley in Philadelphia. The thirteen cars on that line run by electricity are making five hundred and sixty miles per day, more mileage than was made by eighteen horse cars, and the receipts have averaged since the starting an increase of sixty per cent.

Boston.—The creditors of Jerome Redding & Company, electrical engineers and manufacturers of electrical goods, have decided to have the business continued by the assignee, the committee being continued to act in an advisory capacity in co-operation with him. The direct liabilities are about $6,500 and the indirect $500, while the assets nominally aggregate about $12,000. It is thought that the creditors will eventually get their pay in full.

Pittsburg, Pa.—The electric fountain to be donated to Schenley Park, this city, by the Fifth Avenue and Duquesne traction companies has been ordered, but it will not be completed for a month. It will probably be in operation by September 1. The plans are elaborate and the total cost will reach $20,000. The makers promise that it will be the finest of its kind in the world, surpassing even the remarkable fountain in Lincoln Park, Chicago, one of the wonders of that city.

Danville, Ky.—It is reported that a syndicate of wealthy Englishmen have purchased the Cumberland Falls, in Whitley County, and will erect there an immense electric plant, utilizing the falls as a motive power. From this plant they expect to furnish light and power to cities, corporations and individuals at a distance at a nominal cost. They also propose to build an electric passenger and freight railway from Jellico, via Williamsburg and the falls, to some point on the Cincinnati Southern Railway.

Noblesville, Ind.—The officers of the Chicago and Central Indiana Electric road a few days ago filed a petition with the board of commissioners of Marion County, at Indianapolis, asking for the privilege of running their tracks along the highways of said county to Broad Ripple, and thence to the corporate limits of Noblesville. The petition was withdrawn temporarily to arrange some details, and will be filed again. Three lines have been surveyed. It is said a novel storage battery by a local inventor will be tested by the company, and if approved will be used on the road.

Paterson, N. J.—The New Jersey Improvement Company, composed of New York, New Jersey and Philadelphia capitalists, is said to be preparing to build an electric railway between Paterson and New Brunswick, passing through or near Montclair, Orange, Plainfield, South Orange, Bloomfield and Metuchen and skirting the Orange Mountains for thirty miles. The officers of the company are: President and general manager, Jacob L. Stadelman, of Bath, Pa.; secretary, John N. Bethel, of Philadelphia; treasurer, Charles E. W. Smith, of Morristown; directors, Lewis C. Mans, Philadelphia; Roland F. Hill, New York; A. D. Thompson, Plainfield; and William N. Mills, Boston, Mass.

Lancaster, Pa.—The Pennsylvania Traction Company's board of directors have elected Hon. John J. Patterson president of the company. Work will be started immediately on the main line from Philadelphia to Harrisburg, but the first system that will be built will be what is to be called the Lancaster system. This is to consist of five different lines and they are all expected to be completed and equipped by Christmas. The speed of fifty or sixty miles an hour is expected to be attained on the main line, which is intended to compete with the Pennsylvania Railroad for passenger traffic.—A branch of the National Brotherhood of Electrical Workers was organized here recently; twenty-five names were enrolled.

The Law Battery.

Figure 1 represents the Law Battery complete.

Fig. 2 shows the carbon and zinc (negative and positive elements) connected to the cover. The negative element of Law Double Cylinder is a body of carbonized material moulded in the form of a cylinder within a cylinder, weighing 25 ounces, and being 6 inch. long x 3¼ inch. in diameter over all, thus giving an enormous surface for so small a body, there being 147 square inches of exposed carbon surface in this negative element. This is more than double the surface usually found in open circuit negative elements.

The Law Battery depends for its holding-up and recuperating power on this large exposure of the negative element, which takes care of the hydrogen gas created when the circuit is closed. There is nothing in this negative element to deteriorate, for as soon as the cell is thrown out of circuit, or is at rest, the gases dissipate and the element is restored to its normal condition. It is the practice in a great many elements to use a depolarizer, a chemical which undergoes a constant change from being called on during action of the battery to give off oxygen, and oftentimes when the cell is supposed to be at rest. It is this loss of chemical energy which deteriorates and renders useless the average negative element, and the peculiar construction and large exposed surface of the negative element of the Law cell render the use of chemicals unnecessary. The element does not deteriorate with use, and its service is most uniform and reliable. Its maintenance is without cost.

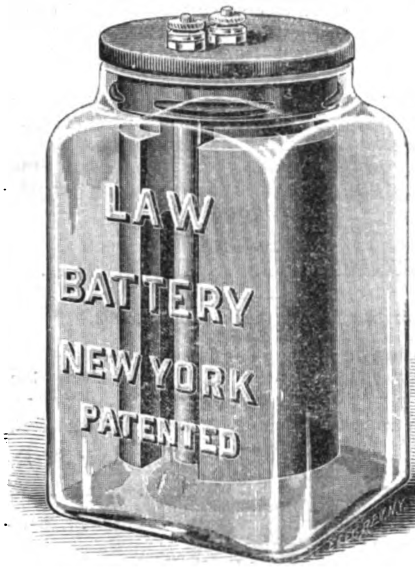

Fig. 1.

The positive element consists of a rod of alloyed zinc and mercury, 5⅛ inch. long x ⅜ inch. in diameter.

The jar is of flint glass, 4⅛ inch. diameter by 8 inch. high. The cover is of material closely resembling hard rubber in appearance. The flange of the cover carries three lugs adapted to engage with small lugs on the inside of the neck of the jar. A slight turn of the cover when in place locks and seals the jar so that the solution cannot evaporate or creep out. This evaporation and creeping is a detriment to the good working of a cell, as thereby the internal resistance is increased, and very frequently corrosion of the connections or wires occurs from this cause.

The zinc and carbon elements are bolted to the cover by means of a carbon-head-screw. Here again the Law cell is unique. Instead of connecting the metal post directly to the negative element a small carbon button is used into which the binding-post is firmly imbedded by a process used only by the Law Company. This button is made of very hard carbon of very heavy pressure, and after the binding-post is placed in position the carbon button is treated to a process which drives out all the air and moisture from the carbon button and renders it thoroughly impregnable to moisture. The button complete ud in half, showing dowel and metal, is illustrated in Fig. 3.

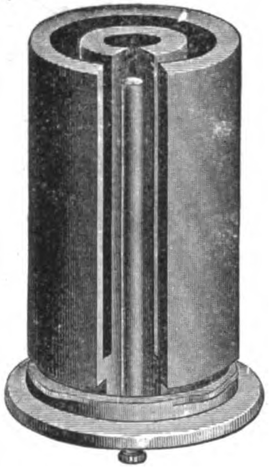

Fig. 2.

It will be observed that the negative element itself is not treated in any way with paraffin or other oils.

It is impossible to connect the metal binding-post to the carbon element direct and so treat the element as to prevent moisture and consequent corrosion at point of contact between metal and carbon, as this corrosion is an electrolytic action, and if enough paraffin was introduced into the element to prevent the absorption of moisture the element would be ruined as a negative element.

The excitant consists of five ounces of prime white granular sal ammoniac put up in a circular pasteboard box, illustrated by cut No. 4.

The complete cell is 8 inch. high over all x 4¼ inch. square, and weighs 4¾ lbs.

The metal binding-posts are tin plated, which prevents, to a great extent, the unsightly appearance caused by handling the binding-posts with wet hands.

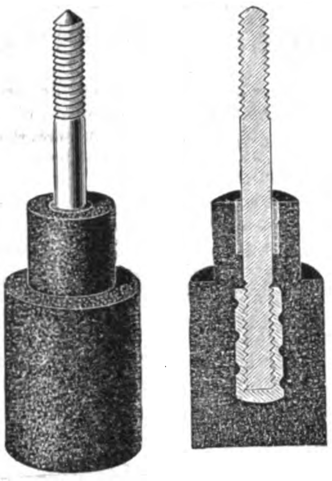

Fig. 3.

The cell is thoroughly adapted for telephone work and for electro-therapeutical work. The company guarantee against corrosion or renewal of any part of the cell excepting the zinc and sal ammoniac, which, of course, wear out with use.

Fig. 5 represents the Clay Porous Cup element made by the Law Battery Company, generally known as the "Leclanche Disque." This element differs from the usual manufactured article from the fact that the lead head has been done away with and a patented connection used instead, which renders corrosion at this point of the element impossible.

Fig. 4.

By referring to illustrations 6 and 7 the different parts of the connector can be understood. The washers next the screw are of pure block tin, having a centrally perforated hub projecting from one side. These hubs fit the hole in the carbon plate and project into the same from the opposite sides. The faces of the washers bear rigidly against the opposite faces of the carbon plate. The screw passes centrally through both of these hubs from one side of the element to the other. A small tinned washer is placed immediately under the head of the screw and bears against the large tinned washer. The thread end of the screw carries a nut which clamps the carbon plate and the washers securely together. Next to this nut on the screw is placed a tinned washer, then a binding nut and last a lock nut. Between the washer and the binding nut the conducting wire leading from the cell is to be clamped.

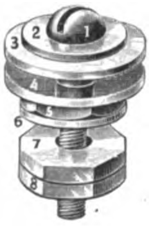

Fig. 6.

It will be observed that the hubs on the tinned washers effectually prevent contact between the carbon plate and the screw, the axis of this screw being held in a position concentric with the hub, and therefore the contact and connection is from the carbon plate direct to, and only to, the pure tinned washer, which covers a large surface each side of the plate.

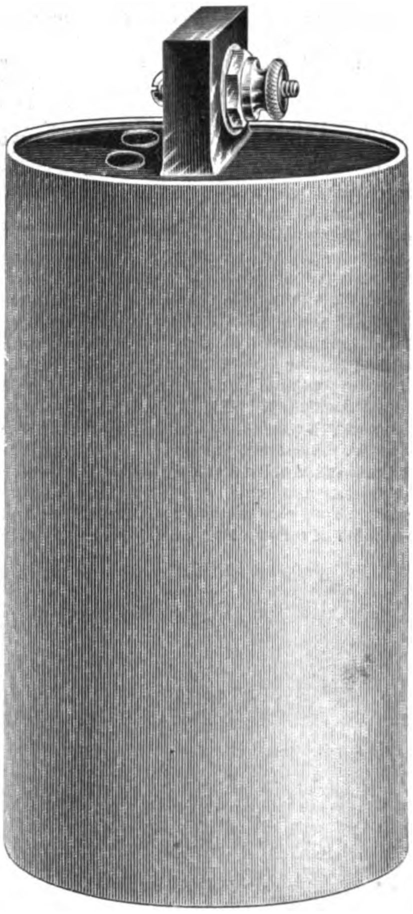

Fig. 5.

An attempt has been made to prevent corrosion by surrounding that portion of the screw standing in the carbon, and which was liable to come in contact with it, by using soft rubber washers or an insulating tape, but both these methods have been found to be ineffective, for after a short period of time the rubber loses its elasticity and becomes a seat for the moisture, or the tape becomes ineffective and draws and holds the moisture between the screw and the carbon, and the electrolytic action causes corrosion.

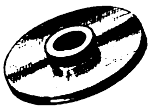

Fig. 7.

The electromotive force of this cell fitted with this element together with an alloyed zinc and good sal ammonia is 1.55 volts, and the amperage is in excess of that possible where a lead head is used, because of the extra resistance and the always present corrosion in the lead head. The crushed carbon and manganese used as a filler is selected with special reference to the work, and a third element is added in the filling which increases the E. M. F. to 1.55 volts.

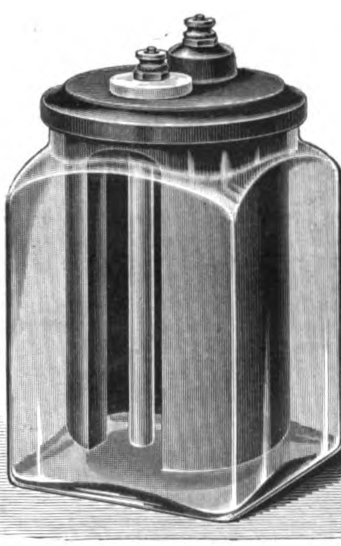

Fig. 8.

This connection has been fitted to all sizes of carbon plates and finds high commendation among the telephone companies, who use it in connection with a standard cell used for long distance work.

Fig. 8 shows a Single Cylinder Carbon Cell also manufactured by the Law Battery Company.

This consists of a cylinder made integral, with cover different from other cells of this class from the fact that the jar used is a round Leclanche jar with pour-out, and the porcelain bushing through which the zinc passes fits into this pour-out in the jar so as to prevent the carbon from turning. In other words, the cylinder is adapted to be used with a stock Leclanche disque jar. The zinc, however, is a special zinc and is an alloy, moulded with lugs at its top which hold it in place in the porcelain bushing and away from the bottom of the jar. This cell is specially intended for bell hangers and for that class of work where a reliable but cheap cell can be used.

Fig. 9 represents a Carbon Porous Vessel with a screw cover. Carbon porous cups as heretofore made for open circuit work have been filled with manganese and then permanently closed by filling or plugging with wax, which it did not pay to remove, so that when the element had lost its efficiency the depolarizing agent could not be renewed, but the complete element went to the ash barrel and a new one substituted. The illustration comprehends a carbon porous cup vessel in combination with a removable carbon cover. The cover being removable allows the renewal of the manganese or depolarizing agent whenever the same has become exhausted or deteriorated through work. This carbon porous cup and cover will do duty for an incalculable number of renewals of the depolarizing mixture.

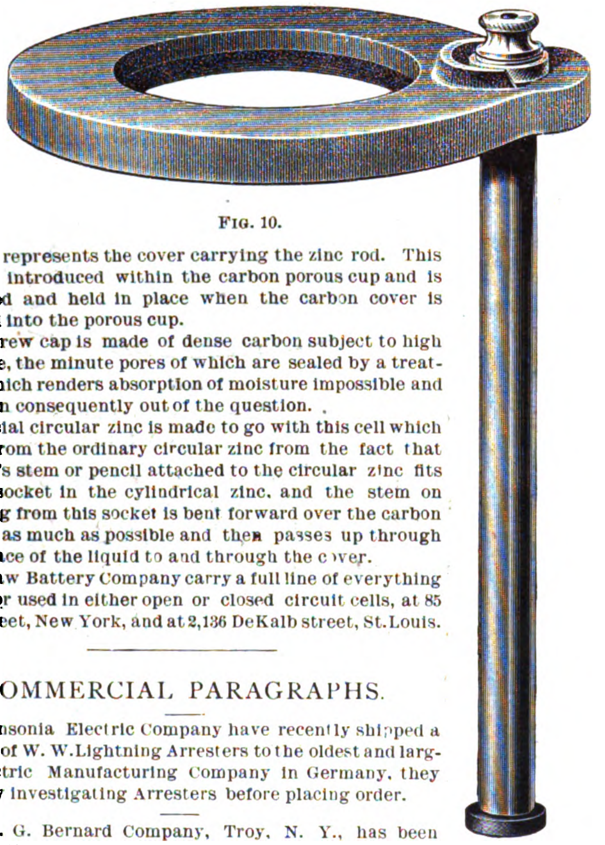

FIG. 10.

Fig. 10 represents the cover carrying the zinc rod. This cover is introduced within the carbon porous cup and is tightened and held in place when the carbon cover is screwed into the porous cup.

The screw cap is made of dense carbon subject to high pressure, the minute pores of which are sealed by a treatment which renders absorption of moisture impossible and corrosion consequently out of the question.

A special circular zinc is made to go with this cell which differs from the ordinary circular zinc from the fact that the zinc's stem or pencil attached to the circular zinc fits into a socket in the cylindrical zinc, and the stem on emerging from this socket is bent forward over the carbon element as much as possible and then passes up through the surface of the liquid to and through the cover.

The Law Battery Company carry a full line of everything needed or used in either open or closed circuit cells, at 85 John street, New York, and at 2,136 DeKalb street, St. Louis.

COMMERCIAL PARAGRAPHS.

The Ansonia Electric Company have recently shipped a number of W. W. Lightning Arresters to the oldest and largest Electric Manufacturing Company in Germany, they carefully investigating Arresters before placing order.

The E. G. Bernard Company, Troy, N. Y., has been awarded the contract for the electric lighting plant at the House of Refuge at Hudson, N. Y. The same firm is just completing the contract for lighting the Troy Orphan Asylum and also the putting in of 700 lights for the Shenandoah mills at Utica. The company reports business very good, despite the dull times.

The United Electric Improvement Company of Philadelphia is doing the electrical work for C. H. Crisman's plant at Branchville, N. J., which will be placed in operation early this month. Branchville will then have the honor of being the best lighted town in North Jersey.

The La Roche Electrical Company, of Sixth and Arch streets, Philadelphia, has purchased Schepper Bros.' six-story mill building, at American and Diamond streets, their business having grown so rapidly as to necessitate extended facilities. The building is 86 by 100 feet in dimensions and for many years was used by Schepper Bros. for the manufacture of worsted and woollen goods. During the past week a force of workmen has been employed putting the building in order for the firm's plant, which they intend to move from their present location. The interior of the western end of the building, fronting on Diamond street, is being remodelled for office purposes.

The Campbell & Zell Company of Baltimore, Md., have published a useful pictorial souvenir of the World's Columbian Exposition, for free circulation at the World's Fair in Chicago, and are distributing thousands of copies. It is formed of infolding leaves containing separate photographic views of the principal buildings, a birdseye view of the whole Fair, and an engraving representing the plant of 2,850 H. P. Zell Improved Water Tube Safety Boilers erected by the company in the main power house at Machinery Hall. (These boilers are equipped with patent petroleum burners for burning the crude product.) In addition to the illustrations in the book there is a valuable directory giving the location of railroad depots and routes, principal hotels, prominent buildings, theatres, museums, monuments, parks, etc., and much information for the visitor who wishes to improve all the opportunities offered by a visit to the Fair.

INCORPORATIONS.

The What Cheer Electric Light and Power Company, Des Moines, Iowa, has filed an amendment to its articles of incorporation limiting its capital stock to $14,000. Directors: J. B. Wilson, J. W. Emery, Henry Horn, W. C. Windell and W. C. Maltby.

The Electric Burglar-Alarm Company, Chicago, Ill.—to manufacture and sell burglar alarms and electrical goods. Capital stock, $250,000. Promoters: Jacob Lindheimer, Geo. D. Hoffman, Jacob Hoffman.

The Pennsylvania Traction Company, Lancaster, Pa.—to construct and operate motors and cables, or other machinery for supplying motive power to passenger railways, etc. Promoters: Robt. McMeen, S. M. Patterson, John D. Skiles, J. Hay Brown, John J. Patterson.

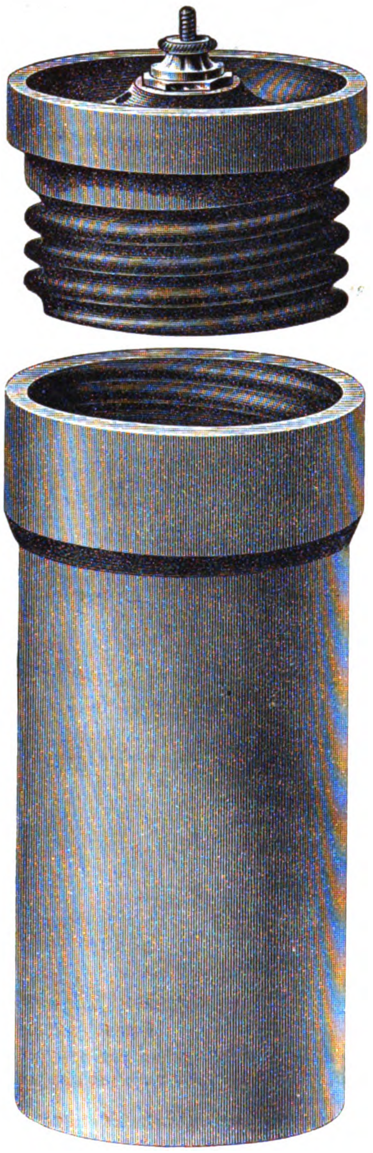

FIG. 9.

The Home Investment and Realty Company, Butte, Mont.—to construct railroads, do electric lighting, storage, etc. Capital stock, $200,000. Promoters: Jno. B. Read, Jas. H. Montieth, Frank S. Smith: Butte.

The Central Light and Power Company, Rochester, N. Y.—to manufacture and sell electricity for producing light, heat and power in Rochester. Capital stock, $25,000. Directors: J. Dewitt Butts, Frank W. Elwood, George Wilson, E. V. Stoddard, Joseph C. Tore, Hiram L. Parker, Isaac W. Butts and F. S. Macomber, of Rochester.

The Montclair Light, Heat and Power Company, Denver, Col.—to produce and sell electricity for light, heat and power, etc. Capital stock, $50,000. Promoters: Edw. W. Rollins, W. G. Fisher, G. A. Batchelder, Jno. H. Poole, Albert E. Grier, Denver.

The St. Vrain Water and Power Company, Ward, Col.—to acquire rights for mining, milling, electricity, power, etc., in Boulder County, Col. Capital stock, $100,000. Promoters: Robt. Haynes Kline, J. Quincy Hunsicker, Louis J. Beacon, Jos. K. Davidson Jr., of Philadelphia, Pa.; Jos. K. Davidson, Germantown, Pa.; John S. Reid, Ward, Col.

A charter has been granted at Harrisburg, Pa., to the West Side Electric Light Company of Luzerne Borough. Capital stock, $10,000.

The Goliad Water and Light Company, Goliad, Texas—to supply citizens of Goliad with water and electric light. Capital stock, $30,000. Promoters: J. H. Elwell, R. R. Stoul, W. B. Campbell, L. A. Mastze, Jno. W. Code, L. Seeligson, Jr., R. T. Davis, all of Goliad.

The South Peoria Street Railway Company, Peoria, Ill.—to construct and operate horse, dummy and electric railways or tramways in Peoria. Capital stock, $100,000. Promoters: Charles A. North, Isaac M. Horbacker, John W. Culbertson.

The General Machine and Electric Company (incorporated in West Virginia), New York City—to manufacture, sell and use electrical and other machinery, and mechanical devices, etc. Capital stock, $5,000,000. Promoters: Granville Woods, N. Y. City; Wm. S. Hanford and Oliver Duncan, Brooklyn.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JULY 4, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

500,827. Railway Signal System. G. L. Thomas, Brooklyn, N. Y., and E. C. Seward, Montclair, N. J. Filed March 6, 1893.
500,851. Electric Locomotive. L. W. Case, Highland Park, Conn. Filed May 9, 1891.
500,937. Conduit Railway Insulator. G. E. Noyes, Washington Grove, Md. Filed Aug. 8, 1892.
500,943. Electric Railway System. F. S. Perrin, Lynn, Mass. Filed April 2, 1892.
501,009. Overhead Electric Railway. J. C. Henry, Westfield, N. J. Filed Sept. 27, 1889.

ELECTRIC LIGHTS AND APPLIANCES.

500,657. Electric Arc Lamp: R. M. Hunter, Philadelphia, Pa. Filed April 3, 1893.
500,670. Incandescent Electric Lamp. W. E. Nickerson, Cambridge, and E. E. Cary, Boston, Mass. Filed April 1, 1893.
500,671. Incandescent Electric Lamp. W. E. Nickerson, Cambridge, Mass. Filed April 3, 1893.
500,829. Electric Arc Lamp. W. A. Turbayne, Detroit, Mich. Filed Nov. 5, 1892.
500,849. Electric Incandescent Lamp. H. D. Burnett, Lynn, Mass., and S. E. Doane, Swampscott, Mass. Filed Oct. 28, 1892.

DYNAMOS, MOTORS, ETC.

500,614. Brush Holders for Dynamo-Electric Machines. H. G. Reist, Lynn, Mass. Filed Jan. 28, 1893.
500,663. Electric Motor. J. MacHaffie, Schenectady, N. Y. Filed Oct. 8, 1891.
500,902. Ring Armature C. W. Jefferson, Schenectady, N. Y. Filed Feb. 13, 1893.

BATTERIES.

500,622. Secondary Battery. W. L. Silvey, Lima, O. Filed July 9, 1892.
500,978. Secondary Electric Battery. C. Theryc and A. Oblasser, Paris, France. Filed Dec. 2, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

500,545. Telephone System. G. L. Anders, London, England. Filed Dec. 1, 1892.
500,957. Ear Piece. R. Seiffert, Chicago, Ill. Filed Feb. 23, 1893.

MEASURING INSTRUMENTS.

500,868. Multiphase Meter. T. Duncan, Fort Wayne, Ind. Filed Sept. 3, 1892.
501,000. Meter for Alternating, Pulsating or Intermittent Electric Currents. T. Duncan, Fort Wayne, Ind. Filed Oct. 10, 1892.

SIGNALS AND SIGNALING APPARATUS.

500,563. Signaling System. W. E. Decrow, Boston, Mass. Filed Dec. 31, 1892.

MISCELLANEOUS.

500,579. Power Transmission. A. L. Ide, Springfield, Ill. Filed July 12, 1892.
500,601. Safety Cut-Out. O. Offrell, Middletown, Conn. Filed Dec. 5, 1892.
500,604. Method of and Apparatus for Separating Ores., C. Q. Payne, Stamford, Conn. Filed April 19, 1892.
500,605. Magnetic Ore Separator. C. Q. Payne, Stamford, Conn. Filed May 22, 1892.
500,606. Device for and Method of Adjusting and Equalizing the Magnetic Density in the Pole Pieces of Magnetic Separators. C. Q. Payne, Stamford, Conn. Filed May 26, 1892.
500,629. Electric Switch. E. Thomson, Lynn, Mass. Filed April 20, 1890.
500,631. Rheostat. E. Thomson, Swampscott, Mass. Filed Aug. 25, 1892.

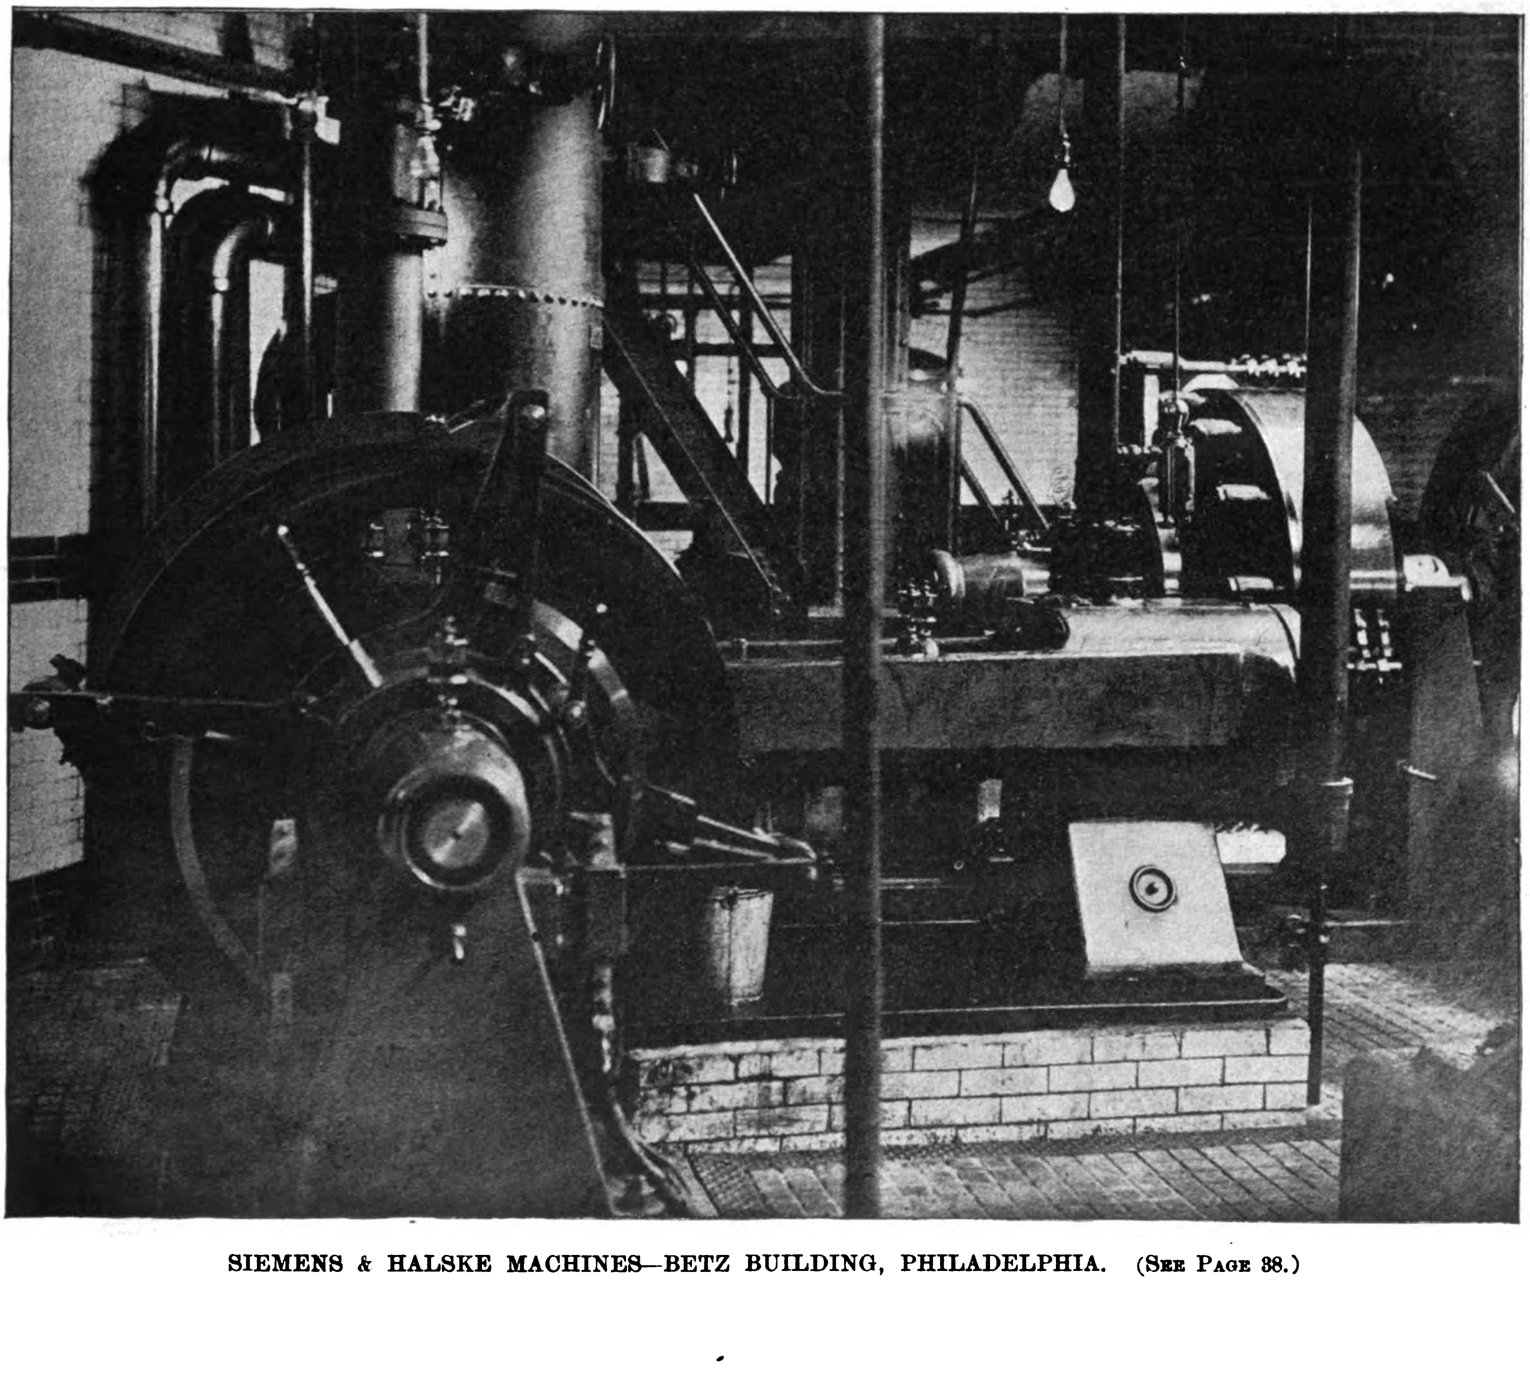
ELECTRICITY.

Vol. V. New York. AUGUST 9, 1893. Chicago. No. 4



SIEMENS & HALSKE MACHINES—BETZ BUILDING, PHILADELPHIA. (See Page 38.)

A Compact Isolated Plant.

Siemens & Halske Dynamos Installed in Philadelphia.

It has long been a matter of regret to electrical engineers that in the designing of buildings in which isolated lighting plants are to be erected there is, as a rule, but scanty provision in the space set apart for this purpose, and for this reason the principal work in arranging such a plant is often to procure engines and dynamos of sufficiently compact construction to accommodate themselves to the available floor space. This has been an important factor in the movement towards direct connected engines and dynamos and the gradual disappearance of belting from plants of this kind.

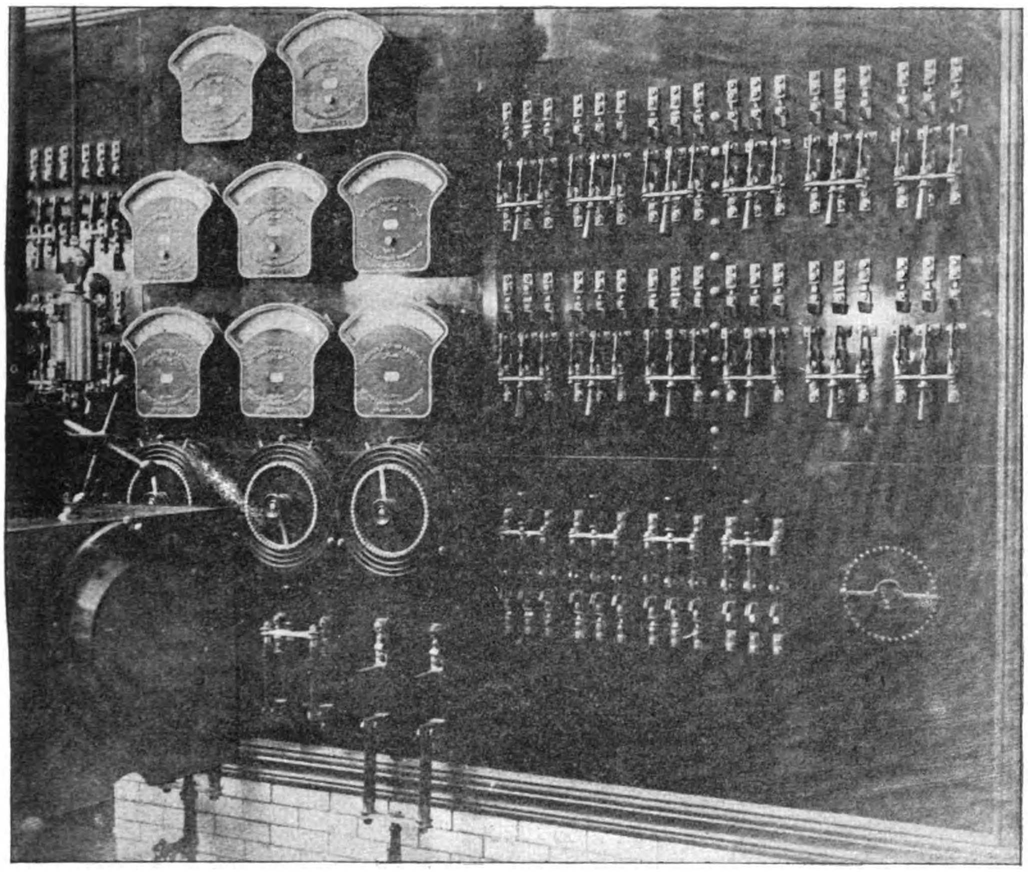


FIG. 1.

The isolated plant of the new Betz building in Philadelphia is probably one of the most compact plants to be found, and its electrical machinery, of the Siemens & Halske type, is the first in this country to be illustrated. The plant has a capacity of four thousand 16 C. P. incandescent lamps and consists of three direct connected Straight Line engines and multipolar dynamos, which with the switchboard occupy a space of but thirty by twenty-three feet, yet leaving sufficient passageway between the machines to give the attendants ready access to any part requiring attention.

Two of the dynamos have each a capacity of 1,600 lamps and the third of 800 lamps. These machines have six internal poles about which the armature revolves. The armature is wound with copper bars, the outside surface of which acts as the commutator, and the corresponding sections between the different poles are cross-connected so that only two sets of brushes are required.

The Frontispiece gives an idea of the way space has been economized in this plant, of which, owing to its location, only a portion can be photographed. The switchboard, shown in Fig. 1, is made of marbleized slate, and in addition to the Weston instruments and Carpenter rheostats contains only the switches for the feeders leading to auxiliary switchboards on each floor, and those connecting the house wiring to the street circuit in case of accident to the house plant.

The wiring is done on the three-wire system, and all the circuits are carried in interior conduit, but the three-wire system is only supplied in order to adapt the plant to the street circuit and is generally not in use. The middle wire of the system has a carrying capacity equal to both the outside wires, and the latter are used ordinarily as one wire and the middle one as the other of a two-wire system.

Fig. 3 shows one of the auxiliary switchboards with which each floor is supplied, containing the cut-outs and in some cases the switches which control the circuits on that floor. The illustration shown is on the thirteenth floor, which is largely utilized as a dining room and contains a number of electroliers and bracket lights that are controlled from the auxiliary board. On the other floors, where the office lights are more accessible, these switches are either dispensed with altogether or placed in convenient positions in the offices.

In addition to the use of separate conduits for each wire, weatherproof and fireproof wire is used, rendering any danger from short circuits almost impossible, and the substantial character of the equipment, which was installed by H. Ward Leonard & Company of New York, leaves hardly any chance of accident or trouble in the operation of the plant.

Personal.

Mr. James W. Godfrey, General Manager of the New York Insulated Wire Company, who has been in Chicago for a long time in charge of the company's large wiring contract at the Fair, has returned to New York.

Prof. James H. Mason, of the Mason Electrical Company, who has been doing the Fair, has returned to New York full of enthusiasm over the big show.

Mr. J. B. Olson has been appointed Manager of the Chicago office of the New York Insulated Wire Co.

Mr. John W. Howells has just returned from a business trip to the City of Mexico undertaken in the interest of the Edison Lamp Works.

World's Fair Notes.

The Department of Electricity has nearly completed arrangements to give a free course of practical lectures on electrical subjects by prominent electrical inventors and scientists. The lectures will be given on three days of the week, viz., Tuesdays, Thursdays and Saturdays, from 3 to 4 o'clock. The directors of the course have secured the use of the Western Electric Company's Scenic Theatre for the hours of the lectures Among the subjects to be handled are the following:

Testing Instruments.
Search Lights.
Electric Lighting by Arc Lights.
The Telautograph.
The Phonograph.
Electroplating.
Electric Railways.
Long Distance Transmission of Power.
High Tension and High Frequency of Alternating Currents.
Primary Batteries.
Electrical Patents.
Electricity in Mining.
Electric Welding.
Ocean Cables.
Underground Cables.
Alternating vs. Direct Currents.
Lightning Effects on Electrical Apparatus.

Each subject is to be treated by a man prominent in his line of work. Invitations have been issued to a number of the most prominent electricians to deliver additional lectures to the ones named above. If the course proves as interesting as it is expected to be, a larger room will be secured in which to deliver the lectures.

The following petition was circulated among the exhibitors in the Electricity Building last week. It was handed to Professor Barrett, Chief of the Electrical Department, for such action as he saw fit to take:

PROF. J. P. BARRETT,
Chief Department of Electricity.

DEAR SIR: There having been more or less said against the electric belts exhibited in this building, and referring to them as fakes, we the undersigned respectfully request that said belts be submitted to the jury for them to test same for voltage, amperage and internal resistance.

We ask this to sustain you in your action in giving them a space, and also in justice to themselves as exhibitors. There are many electrical appliances and belts that are fakes, from which no current can be obtained, and those that do not have merit should be known, especially the exhibitors that you have admitted in this Electrical Building in the World's Fair.

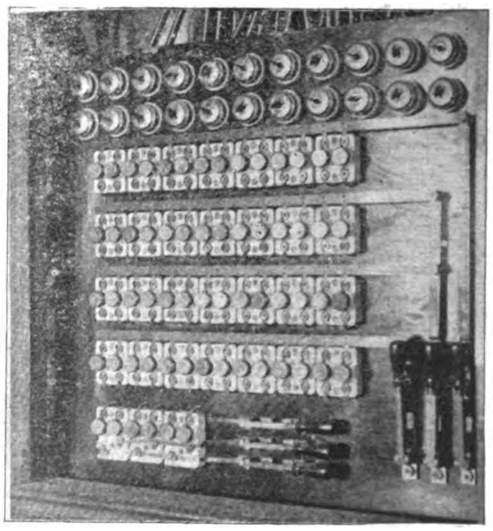

FIG. 2.

A large number of the exhibitors in the Electricity Building have, in conjunction with exhibitors in the other buildings, formed an association, to be known as the Associated American Exhibitors of the World's Columbian Exposition. The object and purpose of the society, as stated in the first announcement, is to observe American week after a manner which will be in direct interest of every American exhibitor in the Exposition.

The name of Dr. Louis Duncan was added to the list of judges of electrical apparatus last week.

The Duration of the Discharges of Induction Coils.[*]

BY H. LOUIS JONES, M.D.

In the course of an investigation into some of the properties of medical induction coils I had occasion to set up an apparatus for counting the rate of vibration of their contact breakers, and so obtained the accompanying tracings, which may be of interest to your readers, because they seem to show that the secondary discharges of induction coils are not so brief as is generally supposed. For particular coil Blaserna worked out the times of 0.000485 second and 0.000275 second as the duration of the make (inverse) and break (direct) discharges, and these figures are usually taken as showing that the discharges are of extremely short duration. The coil used is 7 in. long and 2⅜ in. in diameter. Core small, ¾ in. in diameter; primary turns 100, secondary 8,000 approximately; resistance of secondary 2,750 ohms, wound in two sections, paraffin insulated; weight of hammer, 300 grains; spring of stiff brass, 1½ in. long, ½ in. broad. Contact breaker screw close up to head of hammer, which, therefore, rebounds at once after contact, 52-55 times per second. With 4 volts and 2 amperes, gives 1 in. sparks. Condenser the usual size as fitted.

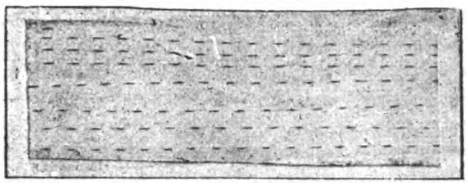

Fig. 1.—Electric Light ~ 100. Length of diagram = one-seventh Second.

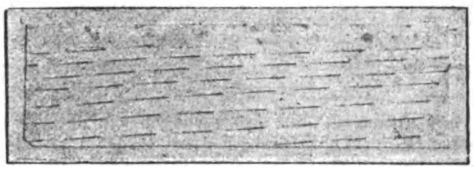

Fig. 2.—"Break" Discharges of Coil. Length of diagram = one-seventh Second.

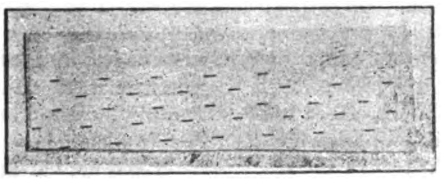

Fig. 3.—" Make " of Coil. Length of diagram = one-seventh Second.

The tracings (Fig. 1, 2, and 3) were taken upon a small revolving drum of metal covered with a strip of blotting paper wetted with starch paste containing iodide of potassium; the liberation of iodine at the positive pole strikes a dark blue color with the starch. This reaction is much more sensitive than that of the ferrocyanide of potassium papers used in Bain's chemical printing telegraph. The drum was fixed upon the axle of a small electromotor, which was joined to a Young's speed indicator (Fig. 4). One terminal of the secondary coil was connected to the rotating drum, and the other to a fine platinum needle which was held against the paper by the hand and was moved from end to end of the revolving drum. The needle was bent near the end into an acute angle or elbow; this was the part used to make contact with the drum, as the point was found to scratch the soft paper. The marks made by the bent elbow of the needle were not at all elongated until the recording surface was made to move, so the shape of the markings is not due to the shape of the surface of the needle. In this way a succession of streaks and intervals was drawn in a spiral upon the cylinder. The paper was taken off the drum and the tracings were photographed at once, as the marks are very fugitive. The figures represent the stripes of paper used, photographed to half-scale.[†]

For purposes of comparison a trace was taken from the alternating electric lighting current. This is shown in Fig. 1. Fig. 2 shows the "break" discharges (positive pole) of the secondary of an induction coil capable of giving 1 in. sparks. Fig. 3 shows the "make" discharges (positive pole) of the same coil, the direction of current in the primary having been reversed. The strips are to be read from right to left, beginning at the right hand top corner.

The speed of rotation recorded was seven revolutions per second, the circumference of the drum 4½ in., the velocity of the surface 31½ in. per second.

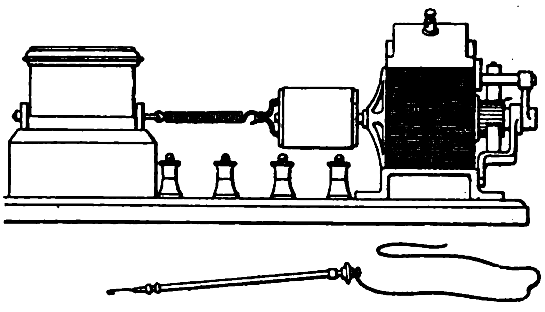

Fig. 4.—Motor, Revolving Drum, and Counter.

The rate of vibration of the contact-breaker works out at 52 to 55 a second; and the rate of alternation of the electric lighting current at 112, the nominal rate of the latter being 100, I believe. The difference between these two figures is probably due to error in the indications of the speed indicator, which is a little difficult to read exactly, but it may show that the alternator at the central station was running a trifle faster than usual on the morning when the trace was taken. On another trial the rate came out at 105. Several tracings were taken on each occasion, and on each of those occasions the several traces agreed among themselves.

Measurement of the photographed tracings gives the mean duration of the discharges as follows:

Break..................0.0134 second.
Make...................0.0046 "

The dotted marks at the top of Fig. 2 were caused by sparks passing through the air to the paper. It is interesting to note that they are not elongated or drawn out. The other marks are very long, and also taper off in a significant way; but no sign of this tapering appearance can be seen in Fig. 3.

The intervals in Fig. 1 (dynamo current) are longer than the marks; and from this we may reasonably infer that the method of recording does not exaggerate the length of the discharge, but rather tends to reduce its apparent duration. The resistance of the damp paper varies a good deal, but its average is rather more than 1,000 ohms.

When the make-and-break tracings are combined, and this can be done very simply by superposing their photographic negatives, it is clear that the intervals which correspond to the periods of no current in the secondary coil are very short indeed—at a rough estimate about 0.001 second, or even less in a total period of 0.019 second. At first I assumed that the short marks must be "break" discharges, and the long ones "make" discharges, but further experiments showed that this was not the case.
